at the upper end of the apparatus the lightest parts of the naphtha vapour from the boiler A, and being itself here the coldest condenses them. The lower down the liquid flows, the higher becomes the temperature of the apparatus, the heavier are the gases it meets, and gradually yields its volatile elements. Thus only the heaviest part of this liquid naphtha, or in other words only the residues reach the boiler A by the pipe *d'*. On the other hand, this very liquid flow serves for fractionating off the vapour rising from A. Entering the space *e*, the latter comes into contact with the bottom of pan *b*, cooled by its liquid contents, condenses and falls on the tray, and flows out through *f' f*. Uncondensed vapours are forced to dive under partition *g*, into the mass of liquid naphtha, thus heating it, yielding to it some heavy vapours and entering the space between *b<sub>1</sub>*, *d<sub>2</sub>*, and *b<sub>2</sub>*; here again it comes in contact with the cooler bottom of pan *b<sub>2</sub>*, condenses and falls on the tray *d<sub>2</sub>* and flows out through *f<sub>2</sub>*, &c. This process may be continued according to the number of pans. The lightest gases which could not be condensed in the apparatus are carried away through the pipe *i* and condensed separately. The boiler is heated by pulverised residues.

The principal results of using this apparatus in practice are as follows: the average difference of temperature between each two neighbouring pans is 30° C., which makes for

seven pans a total difference of  $210^{\circ}\text{C}$ . at the upper and the lower ends of the apparatus. Thus it may contain at the same time the lightest and the heaviest distillation products. The volume of the daily output is 27 times the capacity of the apparatus, which makes in one case 105,000 kilos., the proportion of the naphtha residues being only 40 per cent., while the best apparatus in common use leave not less than 60 per cent. of residues.—N. W. T.

*On the Condensation of Benzene Vapour and of Acetylene under the Influence of the Glow-Discharge.* P. Schutzenberger. *Compt. Rend.* **110**, 889—892.

BENZENE vapour was introduced into the annular space between two concentric tubes by means of a semi-capillary tube, the end of which was then sealed with the blow-pipe. A glow discharge was then caused to pass in the enclosed space by means of sulphuric acid electrodes (as in the Berthelot ozone apparatus). The liquid benzene in the bottom of the tube gradually evaporated and condensed on the active surfaces in the form of a layer of a transparent light yellow substance. Although the author believes that no oxygen was present in the tube at the beginning of the experiment, the substance contained oxygen. The author concludes that *glass under these conditions is permeable*. The time during which the experiment lasted was variable, the inner tube often breaking; no tube withstands the passage of the current for more than six hours when the annular space is filled with benzene vapour, or for more than a few minutes when the space is entirely exhausted.

The amount of oxygen absorbed varied from 0.7 per cent. to 7 per cent. of the product formed (12 analyses). In one case the deposit on the internal and external surfaces was analysed separately and gave the following results:—Deposit on internal surface, C = 90.54 per cent., H = 7.30 per cent., O = 2.10 per cent.; deposit on external surface, C = 87.14 per cent., H = 7.48 per cent., O = 7.0 per cent.

The author regards the following experiment on acetylene as conclusive. The annular space was not sealed in this case, but closed by a surface of mercury. A volume of 250 cc. of the gas was gradually introduced and condensed by means of the glow discharge; the residue of acetylene was then measured, and pure dry hydrogen was introduced and the glow discharge continued for 12 hours. At the beginning of this period an absorption took place corresponding to the volume of the acetylene in the apparatus, after which no further absorption was observed.

The condensed product contained C = 75.0 per cent., H = 8.9 per cent., O = 16.1 per cent. This corresponds to an absorption of 2 centigrammes of water from the exterior. This product does not absorb oxygen from the air. The appearance and weight of the glass are not sensibly altered. After the combustion of the substance, a very slight superficial deposit of alkaline salt on the glass is observed, not weighing more than from 1 to 2 milligrammes. —P. J. H.

*The Action of Litharge on Toluene: Production of Benzene.* C. Vincent. *Compt. Rend.* **110**, 907—908.

BENK and Van Dorp, and after them Lorenz (Ber. **7**, 1096) have shown that stilbene, diphenyl, anthracene, and a liquid hydrocarbon are produced by the action of litharge on toluene at a dull red heat. The author has investigated the reaction at different temperatures. The apparatus consisted of a long iron tube heated by a row of regulated gas burners, connected to a condenser and a wash-bottle containing baryta water. The iron tube was filled with litharge in scales, and toluene was introduced drop by drop into the end of the tube until all the litharge was reduced.

The author obtained the following results—

(1.) At a temperature a little below  $335^{\circ}$  (the melting point of lead) a simple oxidation of the side chain took place, giving rise to benzene and carbonic acid. The oily liquid which distilled over consisted only of the excess of unattacked toluene mixed with 10 per cent. of its weight of benzene.

(2.) At a higher temperature, less benzene is formed, the chief product being stilbene, mixed with other hydrocarbons. The principal reaction is—

(3.) At a low red heat, besides the above compounds, their condensation products are also formed—diphenyl, phenanthrene, anthracene, &c.

(4.) The production of diphenyl is not due to the presence of benzene as an impurity in the toluene, but to the benzene formed by the reaction.—P. J. H.

# PATENT.

*A New or Improved Process for the Purification of Mineral Oils and for Producing Alcohol.* W. P. Thompson, Liverpool. From P. Marix, Paris, France, and N. Notkin, Moscow, Russia. Eng. Pat. 13,653, August 29, 1889. 6d.

NAPHTHA and mineral oils are usually purified by means of strong sulphuric acid, whereby a "black acid pitch" is obtained. The inventor proposes to make use of this "pitch" by mixing with it various vegetable matters, such as wood, straw, paper, &c., which yield glucose when acted on by sulphuric acid. These vegetable matters are either introduced into the oil before treatment with acid or incorporated with the "pitch" thus produced. The mixture is then treated with boiling water for some time, the solution neutralised, filtered, concentrated and fermented. The inventor also proposes to use the pitch, as usually obtained, for absorbing ethylene from illuminating gas, thus forming ethyl sulphuric acid, which when distilled with water yields alcohol and sulphuric acid.—A. L. S.

## IV.—COLOURING MATTERS AND DYES.

*The so-called Trisulphonic Acid.* C. Loring Jackson and G. T. Hartshorn. Ber. **23**, 2143.

THE authors formerly reported the discovery by them of a method of preparing aniline trisulphonic acid (this Journal, 1888, 669). They now find to their surprise and sorrow that what they obtained was simply sulphanilic acid, and that consequently aniline trisulphonic acid has yet to be discovered.

*Homofluoresceïn.* E. Grimaux. *Compt. Rend.* **110**, 1074—1076.

ON heating a mixture of oreinol, chloroform, and soda, Schwartz, in 1880, obtained a crystalline compound to which he assigned the formula  $\text{C}_{23}\text{H}_{15}\text{O}_5$ , regarding it as trimethylfluoresceïn, a homologue of fluoresceïn, which he named homofluoresceïn. Schwartz assumed that the body was formed by the condensation of 1 mol. of methylphthalic acid with 2 mols. of oreinol, the methylphthalic acid, according to his view, being produced by the replacement of two OH-groups in oreinol by two COOH-groups—a view which seems to the author difficult of acceptance, as he considers that the reaction would agree better with the formation of an aurin of the empirical formula  $\text{C}_{22}\text{H}_{15}\text{O}_5$  and the constitution—

As Nencki in 1882, by acting on oreinol with formic acid and zinc chloride, prepared an aurin of the above constitution, the author concluded that Schwartz's homofluoresceïn and this body must be identical, and made

experiments to prove that such was the case. Schwartz's compound was prepared by the published method, being obtained in the form of the soda-derivative, which was twice crystallised from acetic acid; red needles with green reflex were so obtained, containing acetic acid of crystallisation; on drying at 100° the compound lost 31.3 per cent. of acetic acid, Schwartz giving the loss at 31.4 to 31.7 per cent. Nencki's oreinol-aurin was crystallised in a similar way from acetic acid, needles of precisely the same appearance as Schwartz's compound being obtained; on drying at 100° they lost 32.2 per cent. of acetic acid. The two compounds were now closely examined, identical reactions being in all cases observed, for example, both compounds melt at 300°; heated in test tubes, both compounds at a high temperature decompose with separation of carbon and evolution of red fumes; both yield barium salts sparingly soluble in cold water; the alkaline solutions of both compounds are intensely fluorescent.

The compound obtained by Schwartz by nitrifying homofluorescein and acting on the nitro-derivative with ammonia, and to which that chemist gave the formula  $C_{22}H_{20}N_{10}O_{10}$ , assuming that it was a pentanitrodiazamidocompound, when referred to the aurin-type, will be seen to be a hexanitrodiamido-derivative of oreinol-aurin of the formula  $C_{22}H_{10}(NO_2)_6(NH_2)_2O_3 \cdot 11H_2O$ , Schwartz's analytical figures confirming this.

Using resorcinol in place of oreinol in Schwartz's experiment a red-brown solution is obtained, from which acids precipitate a yellow powder identical with the resaurin prepared by Nencki by heating together to 140° resorcinol, formic acid, and zinc chloride.

It is interesting to note that whilst the alkaline solutions of resorcinol-aurin are devoid of fluorescence, those of the corresponding oreinol-compound are extremely fluorescent, but conversely, whilst resorcinol-phthalein in alkaline solution is richly fluorescent, oreinol-phthalein, as stated by E. Fischer, is non-fluorescent.—E. B.

*On Amethyleamphophenolsulphone and its Tetra-nitro derivative: a Yellow Colouring Matter.* P. Cazeneuve. *Compt. Rend.* 110, 961—964.

IN a previous note (this Journal, 1890, 647; see also 1889, 815) a certain class of camphor derivatives called *campho-sulphophenols* was described. The first member of the series yields, on splitting off the methyl group, the body *amethyleamphophenolsulphone*. This body is also formed according to the equation—

The substance crystallises in white scales, soluble in water and alcohol, insoluble in benzene, ether, chloroform, and carbon disulphide. It contains two hydroxyl groups, the one phenolic, the other corresponding to a secondary alcohol. Baryta water gives a precipitate corresponding to the formula—

A monacetic ester is obtained by heating to ebullition with acetic anhydride; the diacetic ester by boiling for an hour with acetic anhydride and sodium acetate. Heated with phenylhydrazine on the water-bath, a liquid compound (difficult to purify) is slowly formed. Hence it follows that the ketonic group of camphor still persists in this compound.

Added gradually to five parts of fuming nitric acid at a temperature of from 0° to 10° the body dissolves without any evolution of gas. A precipitate forms on addition of ice water which, on recrystallisation from alcohol, was found to be the tetranitro derivative,  $C_9H_{10}(NO_2)_4SO_2O_3$ , or more probably  $C_9H_9(NO_2)_3(SO_2)(OH)(ONO_2)O$ . This body is only slightly soluble in water, more soluble in alcohol. It melts at 87° and solidifies at 80°. It distils above 200°, but not without decomposition, and explodes when projected into a red hot crucible. It is a dibasic acid, and gives crystalline salts of an orange-yellow colour, all of them soluble, even those of the alkalis. The barium salt has the formula—

It is obtained in orange crystals containing two molecules of water; the water may be driven off at 100°, leaving a red anhydrous salt of the colour of chromic acid, which readily absorbs moisture from the air and again becomes orange yellow. The nitro body and all its salts dye wool and silk of a splendid yellow or orange colour without the use of a mordant. It is the first nitro colouring matter of the terpene series, of which the fundamental hydrocarbon can only be, according to the author, a hydride of propylbenzene.—P. J. H.

## PATENTS.

*A New Manufacture of Violet and Blue Azo Dyes.* H. J. Haddan, London. From the "Farbenfabriken vorm. F. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 9510, August 10, 1885; amended March 27, 1890. 6d.

THE patentee confines himself to the use of the tetrazo compound of *ortho* tolidine in the production of the above colouring matters (see this Journal, 1886, 427).—O. H.

*Improvements in the Manufacture of Azo Dyes.* J. Y. Johnson, London. From the "Farbenfabriken vorm. F. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 14,424, November 24, 1885; amended March 27, 1890. 6d.

THE patentee disclaims "the use of the Alpha-mono-sulpho acid and the Gamma-disulpho-acid of Beta-naphthylamine;" also the use of "benzyl ethers of the diamidophenols" as stated in the first claim, restricting himself to the "ethyl methyl or amyl ethers." Compare the abstract of original specification, this Journal, 1886, 428.—O. H.

*The Production of Paranitrobenzyl-sulpho Acid, and also Azo Colouring Matters from the Amidobenzylsulpho Acid corresponding to this Nitro-compound.* A. Bang, Leeds. From Dahl and Co., Barmen, Germany. Eng. Pat. 7588, May 7, 1889. Reprint. 4d.

THIS specification has already been abstracted (this Journal, 1889, 611). The amendment made by order of the Comptroller prior to the sealing of the patent is to the effect that the patentee is "well aware that it has been previously proposed to use sulpho acids of amines in the production of mixed azo colours."—T. A. L.

*The Preparation of New Sulphonic Acids suitable for the Manufacture of Colouring Matters.* The Clayton Aniline Co., Limited, and C. Dreyfus, Manchester. Eng. Pat. 10,934, July 6, 1889. 6d.

A METHOD for the production of sulphonic acids from phenyl- and tolyl- $\beta$ -naphthylamine. Zimmer (Ger. Pat. 45,940) describes the production of a new sulphonic acid of phenyl- $\beta$ -naphthylamine. This, according to the present specification, is a mixture of two monosulphonic acids which can be separated by the difference in solubility of their ammonium salts in water. The less soluble one called the A acid forms a sodium salt crystallising in needles free from water, which do not dissolve to fluorescent solutions in water or alcohol, whilst the more soluble one called the B acid forms a sodium salt crystallising in plates containing 3 molecules of water, soluble in water or alcohol to fluorescent solution, 100 kilos. of phenyl- $\beta$ -naphthylamine are dissolved in 400 kilos. of sulphuric acid monohydrate below 50° C., and allowed to stand two days at 15°—20°. The melt is then poured into 1,600 litres of water and boiled till the sulphonic acids separate out as a granular powder. The precipitate is filtered off, washed and suspended in 1,600 litres of water, sufficient ammonia being added to dissolve it. After filtering, the solution is allowed to cool, when the ammonium salt of the A acid separates out. A further quantity can be obtained by evaporating the liquor to one quarter its bulk. The sodium salt of the B acid is precipitated from the filtrate by the addition of

caustic soda or sodium chloride. The quantities of the two acids vary according to the temperature. The lower the temperature the larger the quantity of the A acid. Under the conditions above-mentioned about 2 parts of A and 3 parts of B are obtained. In a similar manner two isomeric acids are obtained from *o*-tolyl- $\beta$ -naphthylamine, which can be separated by means of the calcium salts.—F. A. L.

*Improvements in the Production of Orange-Red Colouring Matters from Flavopurpurin.* O. Imray, London. From the "Farbwerke vormals Meister, Lucius and Brünig," Höchst-on-the-Maine, Germany. Eng. Pat. 11,666, July 22, 1889. 6d.

A process for the production of two nitro-compounds designated  $\alpha$  and  $\beta$  from flavopurpurin—

The  $\alpha$ -compound is produced by the action of nitric acid on flavopurpurin in presence of concentrated sulphuric acid, whereas if glacial acetic acid be used the product will be the  $\beta$ -compound, the latter being a valuable colouring matter and preferable to  $\beta$ -nitro-alizarin on account of its dyeing a yellowish shade. It is obtained by mixing 1 kilo. of finely powdered flavopurpurin with 4—5 kilos. of glacial acetic acid, heating the mixture to 30°—35° C. and slowly adding 0.45 kilo. of nitric acid containing 60 per cent. of  $\text{HNO}_3$ . The temperature is then raised to 40°—45° for about an hour when the nitro-flavopurpurin is filtered off and washed. It dissolves with difficulty in ordinary solvents but crystallises from glacial acetic acid in ochre-yellow needles of melting point 265°. It dyes an orange tint on fibres mordanted with alumina. On reduction it is converted into the corresponding amido-compound which crystallises from acetic acid in brownish crystals and the salts of which are decomposed by washing with water.

—T. A. L.

*An Improved Manufacture of Compounds for Dyeing, Consisting of a Mixture of Nitrite with Basic Amido-azo Compounds, or with the Nitro-Compounds of Aromatic Monamines in the Form of a Paste, and the Application of such Paste for Diazotising.* O. Imray, London. From the "Farbwerke vormals Meister, Lucius and Brünig," Höchst-on-the-Maine, Germany. Eng. Pat. 12,031, July 29, 1889. 6d.

The patent describes the production of a paste for the use of dyers consisting of a mixture of equal molecules of nitrite and of one of the following bases, amido-azo-benzene, amido-azo-toluene, amido-azo-xylene, *m*-nitraniline, *p*-nitraniline, or *m* nitro-*p*-toluidine. For the formation of azo-colouring matters on the cotton fibre it is only necessary that the component which is not to be diazotised should be first fixed on the fibre and the material then passed through the diazo-bath obtained by adding the paste above described to a slight excess of hydrochloric acid.—T. A. L.

*Improvements in or Connected with the Manufacture and Production of Colouring Matters or Dyestuffs.* B. Wilcox, London. From the "Farbenfabriken vorm. F. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 13,665, August 29, 1889. 6d.

The two naphthol disulphonic acids described in Ger. Pats. 40,571 and 44,079, when fused with potash or soda yield dihydroxynaphthalenemonosulphonic acids and trihydroxynaphthalenes. These substances combine in an alkaline solution with the salts of diazo and tetrazo compounds, yielding a variety of azo-colouring matters.—T. A. L.

*Improvements in the Manufacture and Production of Colouring Matters or Dyestuffs.* The Clayton Aniline Co., Limited, P. Brunner and J. Hall, Manchester. Eng. Pat. 14,207, September 9, 1889. 6d.

The bases obtained by the action of sulphur on *p*-toluidine are dissolved in sulphuric acid and diazotised with sodium

nitrite in sulphuric acid. This solution is then combined with an alkaline solution of the sodium salt of the sulphonic acids of the above-mentioned bases, and the whole, after being stirred for some time, is raised to the boil. From the solution thus obtained the colouring matter is precipitated by adding salt, filter-pressed and dried. It dyes unmordanted cotton yellow. The yellow solution is turned deep red by the addition of an excess of caustic soda. In place of the bases first mentioned the sulphonic acids may be employed in a similar manner.—T. A. L.

*Improvements in the Manufacture and Production of Disazo Colouring Matters.* J. Y. Johnson, London. From the "Badische Anilin und Soda Fabrik," Ludwigshaven, Germany. Eng. Pat. 14,222, September 9, 1889. 6d.

The colouring matter described, which dyes unmordanted cotton salmon to orange-brown shades, is produced by the action of phosgene on *p*-amido-benzene-azo-naphthionic acid, and has the formula—

The following method is given for its preparation:—15 kilos. of finely powdered *p*-amido-acetanilide are dissolved in 45 kilos. of hydrochloric acid (containing 32 per cent. of  $\text{HCl}$ ), 200 litres of water, and 200 kilos. of ice, and diazotised with 7 kilos. of sodium nitrite in 21 litres of water. The diazo solution is run into 360 litres of water containing 31 kilos. of sodium naphthionate and 36 kilos. of calcined soda. When the azo compound is completely formed it is filtered off and boiled for some time with dilute caustic soda. By this means the acetyl group is split off, and the sodium salt of *p*-amido-benzene-azo-naphthionic acid is formed and crystallises out on cooling, when it is filter-pressed. To convert it into the disazo compound it is suspended in 450 litres of water, 600 kilos. of ice are added, and phosgene passed through the liquid until it shows an acid reaction. The colouring matter which is insoluble in the acid liquid separates out, and after filter-pressing is mixed with sufficient sodium carbonate to convert it into the sodium salt, and dried.—T. A. L.

*Improvements in the Manufacture, Production and Application of Colouring Matters.* B. Wilcox, London. From the "Farbenfabriken vorm. F. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 14,230, September 9, 1889. 6d.

Moxo- and di-nitroso compounds of the dihydroxynaphthalenes are produced by the action of nitrous acid on the latter, and yield colouring matters which dye mordanted fibres. The employment of the (1:8) dihydroxynaphthalene is disclaimed. An aqueous solution of 10 kilos. of ( $\beta$ 1,  $\beta$ 4) dihydroxynaphthalene (obtained by fusing  $\beta$ -naphthol- $\beta$ -sulphonic acid (Schäffer) with potash) in dilute alkali, is treated with 4.5 kilos. of sodium nitrite, cooled with ice and acetic acid run in until the yellow nitroso compound is completely formed. This is then salted out, filtered, and used as a paste. Wool mordanted with aluminium sulphate, when boiled with it, is dyed a deep dark brown to a black. For cotton-printing chromium acetate is preferably used.

—T. A. L.

*Improvements in the Production of Amido-ory-naphthalin Disulphonic Acid and of Amido-diory-naphthalin Monosulphonic Acid, and the Manufacture of their Diazo-compounds, and of Azo Colouring Matters therefrom.* O. Imray, London. From the "Farbwerke vormals Meister, Lucius and Brünig," Höchst-on-the-Maine, Germany. Eng. Pat. 15,175, September 26, 1889. 6d.

By fusing the  $\beta$ -naphthylamine-trisulphonic acid corresponding to the  $\beta$ -naphthol-trisulphonic acid described in Eng. Pat. 2544 of 1882, with caustic alkalis, two of the sulphonic

groups may be successively replaced by hydroxyl, forming, firstly, amido-hydroxynaphthalene disulphonic acid, and secondly, amido-dihydroxynaphthalene monosulphonic acid. Both these compounds may be diazotised and combined with phenols or amines, or they will react with tetrazo compounds, yielding colouring matters in both cases.

—T. A. L.

*Improvements in the Production of Amido-naphthol-mono-sulphonic Acids, and the Manufacture of their Diazo Compounds and Azo Colouring Matters therefrom.* O. Imray, London. From the "Farbwerke vormals Meister, Lucius, and Brüning," Höchst-on-the-Maine, Germany. Eng. Pat. 15,176, September 26, 1889. 6d.

THE  $\beta$ -naphthylamine disulphonic acids corresponding to the  $\beta$ -naphthol disulphonic acids R and Y described in Eng. Pat. 1715 of 1878, when heated with caustic alkalis to 200°–280° yield amido-naphthol-mono-sulphonic acids which differ from the isomeric acids hitherto known in that they yield diazo compounds. The acids can also be combined with various tetrazo compounds, giving blackish-violet to blue-black dyestuffs. The following table gives some of the reactions of the two acids produced:—

—	R.	Y.
Solution of neutral salts in water.	Violet fluorescence.	Blue.
With ferric chloride.	Dark blue colouration, turning to tan colour.	Dirty claret-red colouration.
With chloride of lime.	Light yellowish brown colouration, which disappears rapidly on adding an excess.	Dark reddish brown colouration, which disappears gradually on adding an excess.
Diazo compound.	Reddish orange.	Canary yellow.
Combination of the diazo compound with R salt* in an alkaline solution.	Claret red.	Violet-black.

\* R salt is the sodium salt of  $\beta$ -naphthol disulphonic acid.

—T. A. L.

*Improvements in the Manufacture of Colouring Matters or Dyes.* A. Remy, R. Kramer, and W. Herking, Neuwied-Weissenthurm, Germany. Eng. Pat. 8389, May 30, 1890. 4d.

A PROCESS for the precipitation of the metallic double salts of the alkylated and non-alkylated mono- and diamido-benzophenones and their sulphonic acids, and also of the tetra-alkylated diamidothiobenzophenones by dissolving them in hot weak acid, adding metallic salts, such as zinc chloride or common salt, and allowing the solution to cool. These double salts, or the original ketones, are then to be reduced with zinc and hydrochloric acid, and the hydrols thus formed are precipitated as double metallic salts by means of zinc chloride and common salt, giving colouring matters which dye cotton mordanted with tannin and tartar emetic blue to reddish-violet shades. Further, the hydrols may be employed as dyestuffs in an alcoholic solution by using them together with a mineral or organic acid.—T. A. L.

## V.—TEXTILES: COTTON, WOOL, SILK, Etc.

*Thermo-Chemical Investigations on Textile Fibres (Wool and Cotton).* L. Vignon. Compt. Rend. **110**, 909–910.

THE author who has previously shown the value of thermo-chemical investigations in the case of silk (this Journal, 1890, 771), now applies the same method to wool and cotton.

The absolute weight of each sample of cotton wool and cotton thread was determined by drying, and it was afterwards exposed to the air of the laboratory so that it might take up its normal amount of moisture and acquire the temperature of the calorimeter. It was then plunged into the calorimeter and the evolution of heat observed.

*Wool.*—Unspun wool and wool in threads was treated by potash, soda, hydrochloric acid and sulphuric acid.

The weight of substance taken varied from 10 to 12 grms.; the volume of the reagent was in all cases 500 cc.

In every case a distinct evolution of heat took place which ceased after five minutes. The results have been calculated for 100 grms. of substance and also for a molecular formula,  $C_{88}H_{119}N_{27}O_{27}S_3$  (= 2,111).

### QUANTITIES OF HEAT EXPRESSED IN CALORIES EVOLVED BY TREATING WOOL WITH DIFFERENT REAGENTS AT A TEMPERATURE OF 11°–12° C.

Reagent.	Woollen Thread, Unbleached.		Unspun and Unbleached Wool.	
	For 100 Grms.	For $C_{88}H_{119}N_{27}O_{27}S_3$ .	For 100 Grms.	For $C_{88}H_{119}N_{27}O_{27}S_3$ .
KHO (1 litre = KHO).....	1.16	24.50	1.37	28.90
NaHO (1 litre = NaHO) .....	1.15	24.30	1.10	23.20
HCl (1 litre = HCl) .....	0.95	20.05	1.00	21.10
H <sub>2</sub> SO <sub>4</sub> (1 litre = $\frac{1}{2}$ H <sub>2</sub> SO <sub>4</sub> ).....	0.99	20.90	1.05	22.20

Considering the difficulty of the experiment, these figures agree remarkably well.

*Cotton.*—Unbleached cotton thread and bleached cotton wool were experimented on. A weight of from 9 to 13 grms.

was taken and immersed in 500 cc. of the solution of the reagent. Cotton is permeated by the liquid more slowly than wool, nevertheless, by agitation, the total evolution of heat was made to take place in from 7 to 8 minutes.

QUANTITIES OF HEAT (EXPRESSED IN CALORIES) EVOLVED BY TREATING COTTON WITH VARIOUS REAGENTS AT A TEMPERATURE OF 11°—12° C.

Reagents.	Cotton Thread, Unbleached.		Cotton Wool, Bleached.	
	For 100 Grms.	C <sub>6</sub> H <sub>10</sub> O <sub>5</sub> .	For 100 Grms.	For C <sub>6</sub> H <sub>10</sub> O <sub>5</sub> .
KHO (1 litre = KHO).....	0·80	1·30	1·40	2·27
NaHO (1 litre = NaHO) .....	0·65	1·05	1·35	2·20
HCl (1 litre = HCl) .....	0·40	0·65	0·40	0·65
H <sub>2</sub> SO <sub>4</sub> (1 litre = $\frac{1}{2}$ H <sub>2</sub> SO <sub>4</sub> ).....	0·38	0·60	0·36	0·58

Bleached cotton evolves more heat with the alkalis than unbleached cotton. This is probably due to the formation of oxy-cellulose during the bleaching.

The author proposes to show in a future note how these and further results bear on the theory of dyeing.—P. J. H.

#### PATENTS.

*An Improved Method of Treating Cotton Fibres, or Masses of Cotton Fibres Preparatory to being Worked Up or Made into Yarns for Weaving or Manufacturing Purposes, applicable also to Fibres, Animal or Vegetable, other than Cotton.* R. S. Burn, Stockport. Eng. Pat. 9904, June 17, 1889. 11d.

THE object of this invention is to subject compressed masses of fibres, especially raw cotton as taken from the bales, to the action of currents of air or of "aeriform fluids" at pressure, in order to loosen them, &c. This has hitherto generally been done in various ways, viz., by beating, blowing and seutching machines, and the principle of this invention is to avoid as completely as possible such rough and harsh treatments which are injurious to the fibres. The cotton taken from the bales is brought into chambers, the inner walls of which have either a smooth or a corrugated or ribbed surface which the author proposes in some cases to cover with vulcanised india-rubber or other strong but soft and elastic material. This serves to make the concussions between walls and fibres as little injurious to the latter as possible. The form of the chambers is that of a cylinder or of a truncated cone. When the fibres are placed into the chambers, strong currents of air are produced in the chambers in various directions, and these currents of air, by producing a quick and violent motion of the masses of fibres, open them up. A pressure of several atmospheres may first be applied, but as the process of treatment goes on, and the masses of fibres become more and more separated, and take a light feathery free and open form, the pressure is gradually reduced so that dust, dirt and other impurities may fall to the bottom of the chamber, whilst the fibres are removed from the chamber by a gentle current of air which drives them through a tube at the top, the valve of which has been opened for the purpose. The time of treatment and pressure vary according to the nature of the masses of fibres to be operated upon.

Instead of air at ordinary temperature it may be useful in some cases to apply currents of hot air or of gases which have a bleaching or purifying effect upon the fibres.—H. S.

*Improvements in the Cleansing or Washing of Wool and like Animal Fibres, and in Apparatus employed therein.* A. Ambler, S. Ambler, and F. Ambler, Wilsden. Eng. Pat. 13,626, August 29, 1889. 11d.

THIS invention consists in applying for wool-washing purposes a closed conduit or channel which has abrupt changes of direction. Into this channel, wool and washing liquid are introduced simultaneously and continuously, the changes of direction effecting an intimate admixture of both, and so a thorough washing and cleansing of the wool. The liquid and dirt are separated from the wool fibres by means of

a straining process, gauze, wirework, grids, &c. being introduced into various parts of the channel for this purpose. The abrupt changes of direction may practically be applied by giving the closed conduit a zig-zag form.—H. S.

*Improvements in the Treatment of Fibres and Fibrous Materials, made of China-grass, Flax, Hemp, and the like Fibres, by which means such can be more easily Cleansed and Bleached.* K. T. Sutherland and G. Esdaile, Manchester. Eng. Pat. 15,333, September 30, 1889. 4d.

THE material is placed in a weak solution of carbonate of soda mixed with mineral oil or wax (1 pint of oil or  $\frac{1}{2}$  lb. of wax to 8 gallons of the solution). The material is worked in this solution (which is used "hot or boiling") from  $\frac{1}{2}$  to 3 hours, according to the state of the fibres, then wrung out, washed in water and dried. When the material is dry, it is placed for some time in paraffin oil, then wrung out and passed into a hot or cold weak solution of sodium carbonate in which it is left from ten minutes to half an hour. Afterwards the material is squeezed out and passed into a vat containing hot or cold water, in which it is steeped, beaten, squeezed or hammered, until it becomes cleansed and bleached. If the result be not satisfactory, the process can be repeated from the steeping in paraffin oil, until the material is completely bleached and cleansed. The advantages of this method of treatment are stated to be that the materials are more easily cleansed and bleached without fear of injuring the fibre, and that they are not liable to "ent"; that the fibre may be spun in short or longer lengths as required; that it will "flock"; and that the waste is less in spinning the fibre in short lengths.—H. S.

#### VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

*Fastness to Light of Substantive Cotton Dyes.* O. Müller. Oest. Woll. u. Leinen-Ind. 6, 288.

SAMPLES of cotton fabrics, dyed with various substantive dyes, were exposed to the light for 14 days with the results given below. The following dyes remained unaltered: Benzoazurine 3 G (treated, after dyeing, with copper sulphate), Chrysamin G and R, Brilliant yellow, Chrysophenin, Hessian yellow, Cureumine S, Mikado orange G, R, and RR, Brahma orange, and Diamine yellow N.

There were slightly altered: Congo eorinth G, B, Benzoazurine 3 G G (treated, after dyeing, with copper sulphate and soaped), Azo-violet, Congo brown G, Benzo-brown G, B, NB, Benzo-black-blue, Mikado brown G, B, Salmon red, Diamine red NO, N, Diamine blue 3 R, Fast pink B and G.

The following were destroyed: Congo red (all shades), Brilliant Congo, Hessian purple NG, B, NB, Benzopurpurin B, 4 B, 6 B, 10 B, Deltapurpurin 5 B, G, Benzoazurine 3 G, G, Azo-blue, Rosazurin BG, Heliotrope, Hessian violet,

Thiazol yellow, Sulphonazurine, Diamine blue B, St. Denis red, Brahma red, Violet-black.

The effect of the treatment with a boiling solution of copper sulphate of cotton goods dyed with Benzoazurin (this Journal, 1890, 289) varies according as the goods have been rinsed or not after dyeing. Repeated rinsing of the dyed cloth before treatment with the copper salt renders the action of the latter useless, the colours then being as little fast as when untreated.—E. B.

## PATENTS.

*Improvements in Bleaching, Disinfecting, Purifying and Preserving Substances, and Apparatus therefor.* G. Brownen, London, and J. Gamgee, Wimbledon. Eng. Pat. 9763, June 13, 1889. 8d.

See under XVIII. C., page 883.

*Improvements in the Manufacture, Production, and Application of Colouring Matters.* B. Willcox, London. From the "Farbenfabriken vorm. F. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 14,230, September 9, 1889. 6d.

See under IV., page 854.

*Improvements in the Method of Preparing Colours for Making Writing Inks.* R. Ashton, Manchester. Eng. Pat. 14,388, September 12, 1889. 6d.

PAPER, vegetable parchment, gelatin, sugar or other suitable carrier is to be coated with a strong solution of a coal-tar dyestuff, dried and cut into portions of a convenient size. When required for use one or more of these pieces is placed in an inkstand with a little water, thus furnishing a writing ink of the same colour as that with which the material was originally coated.—T. A. L.

## VII.—ACIDS, ALKALIS, AND SALTS.

*Some Observations on the Relations of the Ferric and Aluminium Hydroxides and of some Iron and Aluminium Salts to each other.* E. A. Schneider. Ber. 23, 1349—1354.

### A.—RELATIONS OF ALUMINIUM HYDROXIDE TO FERRIC SALT SOLUTIONS.

#### I.—Aluminium Hydroxide and Ferric Sulphate Solutions.

Freshly precipitated aluminium hydroxide precipitates all iron from neutral solutions of ferric sulphate at the boiling as well as at lower temperatures. This, however, cannot be explained by the equation—

but it is known that ferric sulphate solutions dissociate easily into basic salt and free acid, and if such solutions be boiled with aluminium hydroxide, the sulphuric acid which becomes free by dissociation is neutralised by the aluminium hydroxide. The ferric sulphate solution thereby becomes more and more basic, and an accelerated precipitation of basic iron salt is the result.

100 cc. of a weak basic ferric sulphate solution containing 0.5126 grm. of  $\text{Fe}_2\text{O}_3$  and 0.6596 grm. of  $\text{SO}_3$  were boiled with 0.7460 grm. of aluminium hydroxide for an hour and a quarter (1 mol. of  $\text{Fe}_2\text{O}_3$  : 1.4 mols. of  $\text{Al}_2\text{O}_3$ ). The filtrate contained:—grm. of  $\text{Fe}_2\text{O}_3$ , 0.1893 grm. of  $\text{Al}_2\text{O}_3$ , and 0.3980 grm. of  $\text{SO}_3$ , whilst it should have contained 0.6596 grm. if the reaction had been in accordance with the above equation; moreover, the iron is completely precipitated by the aluminium hydroxide, not only at the boiling, but

also at lower temperatures. Dissociation also in this case takes place, but it is preceded by a catalytic influence of the aluminium hydroxide. Time has little influence when the reaction is made at lower temperatures, e.g., two portions of a weak basic ferric sulphate solution, each containing 0.2068 grm. of  $\text{Fe}_2\text{O}_3$ , were gently heated each with 0.7460 grm. of aluminium hydroxide (1 mol. of  $\text{Fe}_2\text{O}_3$  : 3.6 mols. of  $\text{Al}_2\text{O}_3$ ), the first portion for 24 hours, the second only for half an hour. In both cases the filtrate was free from iron; in the first case it contained 0.0904 grm. of  $\text{Al}_2\text{O}_3$ ; in the second 0.0770 grm. of  $\text{Al}_2\text{O}_3$  (as sulphate). The influence of dilution on the reaction made at lower temperatures is in accordance with the fact that with increasing dilution the dissociation of the ferric sulphate continuously increases, and that therefore the same quantities of aluminium hydroxide precipitate larger quantities of iron, e.g., 25 cc. of a ferric sulphate solution which contained 0.2507 grm. of  $\text{Fe}_2\text{O}_3$  were gently heated with 0.7857 grm. of aluminium hydroxide for half an hour (3.2 mols. of  $\text{Al}_2\text{O}_3$  : 1 mol. of  $\text{Fe}_2\text{O}_3$ ); the filtrate contained 0.0773 grm. of  $\text{Fe}_2\text{O}_3$ . But the filtrate of a ferric sulphate solution, diluted to 2,000 cc., containing the same quantity of ferric oxide and treated as before with aluminium hydroxide, contained only 0.0072 grm. of  $\text{Fe}_2\text{O}_3$ . The process varies when the reaction is made at boiling heat. All iron is equally precipitated, in concentrated as well as in dilute solutions. The quantities of alumina, being in solution as aluminium sulphate, are in most cases almost the same, as the following figures will show:—

25 cc. of Ferric Sulphate Solution contain 0.2068 grm. $\text{Fe}_2\text{O}_3$ . The following cc. of water are added to every 25 ccm. of Ferric Sulphate Solution.		Quantities of $\text{Al}_2\text{O}_3$ in Solution after boiling.	No $\text{Fe}_2\text{O}_3$ found in the Solutions.
	Ccm.	Grm.	
I.	25	0.0760	
II.	100	0.0769	
III.	225	0.0768	
IV.	1175	0.0648	
V.	1175	0.0760	

In all these instances the substance was boiled for an hour and a quarter. In the experiments I. to IV. the quantity of aluminium hydroxide was 0.7460 grm. = 0.4888 grm.  $\text{Al}_2\text{O}_3$ , therefore we have approximately the proportion  $3\frac{1}{2}$  mols. of  $\text{Al}_2\text{O}_3$  : 1 mol. of  $\text{Fe}_2\text{O}_3$ . In the experiment V. the proportion was: 1  $\frac{1}{2}$  mol.  $\text{Al}_2\text{O}_3$  : 1 mol.  $\text{Fe}_2\text{O}_3$ .

#### II.—Aluminium Hydroxide and Ferric Chloride Solutions.

Freshly precipitated aluminium hydroxide is quickly and completely dissolved to a brown-red solution at ordinary temperature in neutral and basic ferric chloride solutions. This solution immediately coagulates when very small quantities of sulphuric acid are present, and the precipitate contains various quantities of ferric and of aluminium hydroxide, sometimes even the entire quantity of them, according to the duration of the reaction and the concentration of the ferric chloride solution. The dissociation of the ferric chloride solution begins here because of the catalytic influence of the present aluminium hydroxide, the hydrochloric acid which becomes free combines with the aluminium hydroxide, forming aluminium chloride, and the ferric hydroxide remains in solution in its colloid modification.

Aluminium hydroxide has the same relations to ferric nitrate solutions as to the just described ferric chloride solutions.

### B.—RELATIONS OF FERRIC HYDROXIDE TO ALUMINIUM SALT SOLUTIONS.

#### I.—Ferric Hydroxide and Aluminium Sulphate Solutions.

Freshly precipitated ferric hydroxide is dissolved easily and in considerable quantities in concentrated aluminium sulphate solutions. A weak basic aluminium sulphate solution, containing 80.7 grms. of  $\text{Al}_2\text{O}_3$  and 0.1287 grm. of

$\text{Fe}_2\text{O}_3$  per litre, was heated for some time on the water-bath with dry ferric hydroxide, until a precipitate was obtained on the cooling of the liquid. The resulting dark brown-red solution contained 66.73 grms.  $\text{Al}_2\text{O}_3$  and 6.62 grms.  $\text{Fe}_2\text{O}_3$  per litre, and was evaporated to dryness without being decomposed. By subsequently adding water a basic salt was precipitated, showing approximately the following composition:  $\text{SO}_3, 3\text{Fe}_2\text{O}_3, 3\text{H}_2\text{O}$ . The formation of this compound cannot result but from the influence of a part of the sulphuric acid which was combined with the alumina, whilst the alumina becoming free, is dissolved in the aluminium sulphate which is present in excess. In this case ferric hydroxide acts as a basis which is stronger than aluminium hydroxide.

## II.—Ferric Hydroxide and Aluminium Chloride Solutions.

Freshly precipitated ferric hydroxide is dissolved in neutral aluminium chloride solutions in considerable quantities, if gently heated for some length of time. If, however, a part remains suspended in the solution, and is collected by means of a filter and washed, then the water always assumes a yellow colour. The ferric hydroxide thus collected on the filter now easily dissolves in larger quantities of water, forming an intensely red-brown solution, showing fluorescence. The results of the experiments were as follows:—

100 cc. of an aluminium chloride solution which contained 0.858 gm. of  $\text{Al}_2\text{O}_3$ , dissolved a quantity of ferric hydroxide containing 0.820 gm. of  $\text{Fe}_2\text{O}_3$ ; 0.752 gm. of  $\text{Fe}_2\text{O}_3$  were coagulated by a minute quantity of sulphuric acid. The resulting solution appeared light yellow. 0.717 gm. of  $\text{Al}_2\text{O}_3$  remained dissolved, and 0.141 gm. of  $\text{Al}_2\text{O}_3$  were precipitated. 100 cc. of the same solution, treated with the same quantity of ferric hydroxide, and diluted with water to 1,000 cc., dissolved a quantity of ferric hydroxide containing 1.747 grms. of  $\text{Fe}_2\text{O}_3$ ; 1.691 grms. of  $\text{Fe}_2\text{O}_3$  were coagulated by a minute quantity of sulphuric acid. The resulting solution appeared dark brown, 0.818 gm. of  $\text{Al}_2\text{O}_3$  remained dissolved, and 0.040 gm. of  $\text{Al}_2\text{O}_3$  were precipitated. A strong basic aluminium chloride solution (1 mol. of  $\text{Al}_2\text{O}_3$ ; 7 mols. of  $\text{HCl}$ ) showed the same relations to ferric hydroxide as described. The author adds that he has hitherto not found a satisfactory explanation of these experiments.

## III.—Ferric Hydroxide and Aluminium Nitrate Solutions.

Aluminium nitrate differs from aluminium chloride inasmuch as solutions of the first, containing the same quantities of alumina as the aluminium chloride solutions used in the above-described experiments, dissolve only very small quantities of ferric hydroxide. But when ferric hydroxide is mixed with an aluminium nitrate solution of the said concentration, and water afterwards added, then a considerable quantity of ferric hydroxide is dissolved. 100 cc. of an aluminium nitrate solution, containing 0.858 gm. of  $\text{Al}_2\text{O}_3$ , dissolved only 0.024 gm. of  $\text{Fe}_2\text{O}_3$ , after having been gently heated for some length of time. This solution was not coagulated by a minute quantity of sulphuric acid. But 100 cc. of the same aluminium nitrate solution, treated with the same quantity of ferric hydroxide, and diluted to 1,000 cc., dissolved a quantity of ferric hydroxide containing 1.148 grms. of  $\text{Fe}_2\text{O}_3$ . That part of the ferric hydroxide which remained unaffected after being washed with much water, gave a solution of colloid modification.

The author finally adds some remarks upon the relations of aluminium chloride solutions to very small quantities of sulphuric acid. It is known that aluminium hydroxide will be precipitated from basic aluminium chloride solutions if the minutest quantities of sulphuric acid be added. The author considers it a new item that acid aluminium chloride solutions are also coagulated by sulphuric acid, e.g., an acid aluminium chloride solution (1 mol.  $\text{Al}_2\text{O}_3$ ; 7.2 mols.  $\text{HCl}$ ), containing 0.1894 gm.  $\text{Al}_2\text{O}_3$  in 400 cc., gave a precipitate of 0.0486 gm. of  $\text{Al}_2\text{O}_3$  on adding a very minute quantity of sulphuric acid, this being 25.6 per cent. of the total quantity of alumina present. Moreover, the author finds that solutions of aluminium

chloride coagulate in larger quantities by sulphuric acid if they have been prepared from aluminium hydroxide which was kept for some time in ammonia water, than if they have been prepared from freshly-precipitated aluminium hydroxide.—H. S.

## The Action of Hydrogen Dioxide on the Oxides of Manganese. A. Gorgen. *Compt. Rend.* **110**, 857—859.

See under XXIII., page 895.

## On Soda-Alum. E. Augé. *Compt. Rend.* **110**, 1139—1140.

THE author shows how unreliable are the data given in chemical text-books and treatises with respect to the properties of soda-alum.

Statements.	Facts.
(1.) Soda-alum is exceedingly efflorescent and falls to powder after a few days' exposure (all authors).	(1.) Soda-alum is but slightly efflorescent and keeps without alteration for months.
(2.) Its solubility is considerable. 100 parts water dissolve 110 parts soda-alum at 16° C. ( <i>Dictionnaire de Wurtz</i> ).	(2.) 100 parts water dissolve 51 parts soda-alum at 16° C.
(3.) A solution of soda-alum boiled loses its property of crystallisation ( <i>Muspratt, Wagner, &amp;c.</i> ).	(3.) A solution of soda-alum may be boiled indefinitely without losing the property of crystallisation.

If a solution containing aluminium sulphate and sodium sulphate in the proper proportions is boiled down to above 38° B. (hot); such a solution on cooling yields an amorphous paste in which even microscopically no crystals can be observed. The formation of this amorphous mass is solely due to the high concentration of the liquor, and not a function of the temperature. If same solution is cooled down before sp. gr. 38° B. is reached crystals of soda-alum are obtained. The amorphous mass between 7° and 25° C. parts gradually with its mother-liquor and is transformed into crystals of  $\text{Al}_2\text{O}_3, 3\text{SO}_3, \text{Na}_2\text{O}, \text{SO}_3, 24\text{aq.}$  For layers 5 cm. in thickness the crystallisation is complete in three days. Above 28° C. the transformation into a crystalline mass is extremely slow, at about 0° C. crystals of soda-alum are formed accompanied by crystals of sodium sulphate. This latter phenomenon explains statement No. 1, the soda-alum obtained in the laboratory having been mixed with sulphate of soda.

According to the foregoing the manufacturer must concentrate the solution of the two sulphates up to 39°—43° B., then cool and drain the amorphous mass, the mother-liquor draining off, representing about quarter of the whole mass, will carry nearly all impurities away; after the crystallisation is complete at about 15° C. the crystals are dried. (See abstract of *Eug. Pat.* 11,975, on next page.)—K. M.

## On the Oxides of Manganese obtained in the Wet Way. Second Part: Manganous Acid. A. Gorgen. *Compt. Rend.* **110**, 1134—1137. (See this Journal, 1889, 541 and 774.)

A CLOSE study of the methods of preparation of binoxide of manganese and of the oxides obtained has led the author to the conclusion that it is practically impossible to isolate the pure hydrate of manganese peroxide. The best way to obtain the hydrate consists in mixing cold and strongly acidified solutions of nitrate of manganese and permanganate of soda; but even by this method it is impossible to obtain hydrated binoxide of manganese free from manganous oxide.

The hydrated binoxide or manganous acid reddens blue litmus and combines with soluble basic oxides producing manganites; it decomposes carbonates, acetates, and even sulphates. The composition of the manganite of potassium obtained from the decomposition of the acetate by the hydrate of the peroxide is expressed by the formula  $25(\text{MnO}_2)_2\text{K}_2\text{O}$ , and the corresponding soda compound by

$25(\text{MnO}_2)\text{Na}_2\text{O}$ ; while the manganites obtained in presence of acetates and sulphates vary from  $3(\text{MnO}_2)\text{K}_2\text{O}$  to  $9(\text{MnO}_2)\text{K}_2\text{O}$ . The anhydrous binioxide acts as an indifferent oxide; the presence of manganous hydrate, however, seems to lend it an acid character. An interesting reaction was observed by the author. If to an alkaline (potash) solution of permanganate of potash which does not appreciably decompose when cold or on boiling manganous hydrate or still better manganite of potash  $5(\text{MnO}_2)\text{K}_2\text{O}$  is added, these two compounds are dissolved without evolution of oxygen and the solution turns a green colour. The lower oxides are evidently oxidised and the permanganate reduced to manganate.—K. M.

*New Mode of obtaining Crystalline Metallic Oxychlorides; the Oxychlorides of Copper.* G. Rousseau. *Compt. Rend.* **110**, 1261–1264.

In a previous paper the author has shown that a crystalline ferric oxychloride may be obtained by heating a very strong solution of ferric chloride with the carbonate of an alkaline earth. He finds, contrary to his first expectations, that the method is not general, but confined to a small number of chlorides which are either extremely soluble in water or form hydrates of slight complexity capable of undergoing aqueous fusion. In the contrary case amorphous precipitates are obtained, as for instance from solutions of aluminium chloride. In accordance with Berthelot's principle of maximum work the decomposition of such chlorides is only possible when the heat of combination of the metal with chlorine does not exceed its heat of combination with oxygen by more than 4.8 cal., i.e., the difference between the heats of formation of hydrochloric acid (diluted) and water (in the liquid state). This at once limits the reaction to the chlorides of tin, titanium, antimony, bismuth, magnesium, zinc, and iron. Certain exceptions are, however, apparent; thus the formation of atacamite,  $3\text{CuO}, \text{CuCl}_2, \text{H}_2\text{O}$ , takes place easily under the most varied conditions although the difference between the heat of formation of cupric chloride and cupric oxide is greater than 4.8 cal. being, in fact, 6.8 cal. Berthelot explains this, however, by showing that although it is inexplicable from the heat of formation of  $3\text{CuO}, \text{CuCl}_2$  which is insignificant, yet an adequate cause is found in the heat of hydration of this salt, which is 10.9 cal., a quantity large enough to determine the reaction. Starting from these considerations one would expect to obtain oxychlorides of different compositions stable under different conditions of equilibrium, by the use of small quantities of water and higher temperatures, thus tending to dissociate the hydrated chloride and cause the formation of a notable proportion of the anhydrous salt. The author therefore experimented on the action of calcium carbonate, in the form of marble, on cupric chloride,  $\text{CuCl}_2, 2\text{H}_2\text{O}$ , when heated in sealed tubes at  $150^\circ\text{--}200^\circ\text{C}$ . After 48 hours a small quantity of a new crystalline oxychloride,  $\text{CuCl}_2, \text{CuO}, \text{H}_2\text{O}$ , was obtained; it was easily decomposed by water and was freed from the excess of unaltered cupric chloride by dissolving out the latter with boiling alcohol; by using a higher temperature the yield was greater and at  $250^\circ\text{C}$ . in the presence of natural magnesium carbonate (giöbertite) the crystals became larger ( $5 \times 2\text{ mm.}$ ). The new oxychloride forms yellowish green hexagonal tables which lose their water of crystallisation above  $250^\circ\text{C}$ . while retaining their shape; at dull red heat they decompose. When brought into contact with water they lose their transparency and their tint alters to pure green; at the same time hydrochloric acid is set free and they are found to be converted into atacamite (*v.s.*). The same reaction occurs when the salt dehydrated at  $100^\circ\text{C}$ . is used; a green colloidal mass is first formed which gives a pseudo solution, clear by transmitted, turbid by reflected light, and precipitated by the addition of an alkaline lorde.

By increasing the quantity of water used with the original ferric chloride to the proportion corresponding to the formula  $\text{CuCl}_2, 5\text{H}_2\text{O}$ , the new oxychloride is no longer modified, and on exceeding this limit and heating for three days at  $180^\circ\text{--}200^\circ\text{C}$ . atacamite is obtained identical with the natural variety; this constitutes a new method of pro-

ducing this substance essentially different from that employed by Debray. More diluted liquids give poor results. Work on similar basic salts is in progress.—B. B.

## PATENTS.

*Improvements in the Manufacture of Soda-Alum.* E. Augé, Montpellier, France. Eng. Pat. 11,975, July 27, 1889. 6d.

In the usual way of manufacturing soda-alum, solutions of equivalent parts of aluminium sulphate and sodium sulphate are heated to a temperature not exceeding  $60^\circ\text{C}$ ., and allowed to crystallise. The improvement consists in establishing the degree of concentration of the final liquor; this should not exceed at any stage of the process a density of about 70 Tw. at  $50^\circ\text{C}$ ., otherwise no crystallised alum will be obtained; whilst on the other hand a lower density interferes considerably with the yield of crystals. The required concentration can be obtained approximately by using a solution containing the molecular weight of aluminium sulphate per litre at  $50^\circ\text{--}60^\circ\text{C}$ ., and suspending therein the required quantity of pure anhydrous sodium sulphate. When all the sodium salt is dissolved, the clear liquor of 70° Tw. is allowed to cool in crystallising vessels, the crystals separated, whilst the mother-liquor returns to the process. (See also preceding page.)—H. A.

*Improvements in Generators for making Carbonic Acid Gas.* E. S. Chavasse, Ombersley. Eng. Pat. 12,346, August 3, 1889. 8d.

The object of this invention is to render the working of the generator automatic. Besides a pump for the supply of the whitening and water there are mechanical stirrers for the intimate mixing of the carbonate with sulphuric acid, the supply of which is regulated automatically by the height of the gas-holder in the following way. The top of the holder is connected by means of a chain leading over pulleys to a vertical rack, provided with slides and moving in guides. The rack is geared with a lever arm in the form of a toothed sector; the arm is centred on a pin and the other end formed as a small toothed sector to gear with a similar toothed sector on the plug of an earthenware tap on the vitriol supply pipe. When the holder is rising, the rack is set in downward motion, and so checks the tap; when the holder is falling, the supply of vitriol is in the corresponding way augmented; and when the holder is at its lowest point, the lever will fall out of gear altogether and shut off entirely the supply of vitriol. At this juncture the generator may be emptied of its spent contents by means of a sluice valve at the bottom, and carbonic acid from the holder will simultaneously enter into the generator (by means of a pipe provided with a back-pressure valve), thus preventing access of air and subsequent dilution of the carbonic acid.—H. A.

*Improvements in or Connected with the Manufacture of Acetic Acid, and in Apparatus therefor.* J. Farmer, Pollokshields. Eng. Pat. 13,264, August 22, 1889. 11d.

In the usual way of manufacturing acetic acid, acetate of lime is decomposed in a still with hydrochloric acid, and the escaping acetic acid passed through purifiers, which retain the tarry matters. These purifiers are liable to block up, and in consequence of the pressure exercised there is a frequent escape of acetic acid from the joints of the still. To obviate this nuisance the still is provided with two lids, an inside lid, made of gun-metal or stone, and an outside stone lid, jointed over the whole top. The inside lid is supported on its vertical lip in an annular gutter, jointed to the top-outside part of the still and luted with the purifying liquor. In distilling off the acetic acid from the charge, it passes through the seal (which may consist of pure acetate of lime and hydrochloric acid, with some paraffin on the outer seal), and from hence through the space between the two lids to the condenser, without exercising any considerable pressure.

Towards the end of the reaction the charge is steamed up; this is effected by means of a perforated copper pipe with stuffing-box and fittings for its withdrawal from the still, when not in use; the choking up of the perforations with mud is thus obviated.

The specification contains the drawings and description of another still, in which facilities are given for the cleaning out of the annular gutter.

The application of the improvements to an ordinary acetic acid still is also described and illustrated.—H. A.

*An Apparatus for Generating Carbonic Acid Gas under Pressure, to be used in Forcing or Raising Fermented Liquors from one Vessel to another.* C. Estcourt, Manchester. Eng. Pat. 13,309, August 23, 1889. 8d.

In this apparatus the supply of carbonate or bicarbonate is regulated automatically by the pressure of carbonic acid in the vessel. The generator is a cylindrical vessel with hemispherical bottom and a lid on the top. The pressure

THE GENERATION OF CARBONIC ACID.

is made to act on the piston, *g*, of a small cylinder, *f*, open at the bottom, which is fixed to the under part of the lid *c*. On the piston *g* is suspended a cage *m* containing the carbonate, which dips in the acid. The piston rod *h* extends through the lid, and is provided on its upper part with a support for weights *l*, whereby the pressure of gas to be obtained is capable of being adjusted and regulated to the greatest nicety.—H. A.

*Improvements in Treating Liquid Acid Residues containing Iron to obtain Products therefrom.* M. N. d'Andria, Manchester. Eng. Pat. 13,575, August 28, 1889. 4d.

The liquid acid residues from cleaning iron, previous to tinning, galvanising, wire-drawing, &c. consist of sulphate of iron and sulphuric acid. It is proposed to utilise this for the manufacture of iron pigment and magnesium sulphate. Milk of magnesia is added and the iron thus precipitated oxidised with a blast of air. After undergoing the usual processes the iron oxide will be available as a pigment, whereas the filtered liquor is boiled down for the manufacture of magnesium sulphate.—H. A.

*Improvements in the Preparation of Alkaline Cyanides and in Apparatus therefor.* H. Grüneberg, Köln, H. Flemming, Kalk, and W. Siepermann, Elberfeld, Germany. Eng. Pat. 13,697, August 30, 1889. 8d.

The invention consists in passing ammonia over a mixture of alkaline carbonate and charcoal at a dark red heat, and subsequently raising the temperature to a bright red in an atmosphere free from ammonia. The operation is performed in a series of vertical retorts, which are set in a furnace in such a way that the fire gases strike first on the lower part of the retorts, heating this to bright red, and in returning, the higher part to dark red. The ammonia is supplied from the top of the retort by means of a vertically adjustable pipe, which is introduced almost as far as the bright red part of the retort. The liquid products of the reaction are collected in a mutual receiver. The remaining mass in the retorts is boiled out with water and the cyanide separated in the usual way—or, in the case of potassium cyanide precipitated with sodium carbonate.—H. A.

*An Improved Process for Recovering Valuable Substances from the Mother-Liquor Resulting from Treatment of Copper Ores.* E. de Cuyper, Perennes-lez-Binche, Belgium. Eng. Pat. 13,726, August 30, 1889. 8d.

The object of this invention is the separation and utilisation of the zinc, sulphate of sodium, and iron contained in the liquors resulting from the treatment of copper ores by chlorination.

The liquor is evaporated down to a pasty condition in special chambers, by causing a fine spray (caused by a blast or agitation) of the liquor to meet the gases from a gas furnace. Hydrochloric acid and chlorine will be given off and a mixture of ferric oxide, oxychloride of zinc, sulphate and chloride of sodium remains. Water will dissolve the latter three constituents; zinc is precipitated by addition of carbonate or sulphide of sodium. It is proposed to treat the solution of chloride and sulphate of sodium with sulphuric acid and allow the sulphate of sodium to crystallise, or else to treat with bicarbonate of ammonium for the manufacture of alkali.

Instead of boiling down to pasty condition the liquor may be evaporated to 40° B. and the sulphate of sodium and ferric chloride fished out as they separate. The fished salts are calcined, the sulphate of sodium dissolved out and obtained by cooling down the solution to -3° C. The mother-liquor from the fished salts contain the zinc, which is precipitated as described before.—H. A.

*Improvements in Apparatus for Evaporating Brine and the like under a Vacuum.* W. Young, Droitwich. Eng. Pat. 13,814, September 2, 1889. 6d.

BRINE is evaporated under vacuum and the salt collected by means of mechanical rakes, or an endless screw, and deposited in pockets or boxes, which are in direct communication with the evaporating vessel. The boxes are provided with tight-fitting doors, which allow of the occasional removal of the salt.—H. A.

*Improvements in and Connected with Apparatus for Evaporating Brine and the like in Vacuum.* W. Young, Droitwich. Eng. Pat. 13,816, September 2, 1889. 8d.

The object of this invention is to produce salt in a continuous manner with economy of fuel and employment of unskilled labour. The apparatus consists of a conical vessel *A*, provided with a cone-shaped lid, and with appliances common to most vacuum pans. The bottom cone is narrowed down to a pipe *B*, 24 ft. long, dipping into a pan *C* fed with brine and preferably kept warm by waste heat from any available source. Part of the tube and the lower cone are surrounded with a steam-jacket, *A*<sup>1</sup>, *B*<sup>1</sup>. The upper cone is connected by a swan-neck *F* with the condenser *G*, terminating at the bottom in a pipe *K*, which passes down to a water tank; the height of this pipe should

of course be such that the water within will be below the bottom of the condenser. The condenser is connected with an air-pump at Q. In starting, the brine is drawn by the

THE EVAPORATION OF BRINE.

pump up the 24-ft. pipe until it reaches the middle of the boiling chamber, and is kept at this level by the vacuum—as is the case in Torricelli's experiment. Steam is now admitted in the jacket, and the vapours given off by the brine are condensed; as the brine becomes more concentrated, salt will separate and drop down the column of liquor in the tank below, and fresh brine will rise up in its place. The salt is continuously removed out of the bottom pan by means of rakes. It is obvious that the brine level in the bottom pan will influence the brine level in the boiling chamber.—H. A.

*Improvements in obtaining Ammonia, Chlorine, and Hydrochloric Acid from Ammonium Chloride, and in the Apparatus Employed therein.* F. Bale, Droitwich. Eng. Pat. 15,649, October 5, 1889. 8d.

Oxide of manganese in powder is suspended in molten chloride of zinc at a temperature below 350°C. and powdered chloride of ammonium introduced in the mixture. Ammonia is given off, and a chloride of manganese or an oxychloride is formed. The last traces of ammonia are eliminated by passing cold and dry air through the mixture. The temperature is then raised and hot and dry air introduced; the chloride or oxychloride is thus decomposed into chlorine (the first gases contain 12–20 per cent. of Cl) and oxide of manganese regenerated. When steam is used in place of dry air, hydrochloric acid is given off. The last traces of chlorine or hydrochloric acid are removed by a current of cold air and a new quantity of ammonium chloride added as before.

The process is carried out in retorts lined with ganister and “a layer of the fused chloride of a metal, whose fusion point is considerably above the temperature required for these reactions.” The retorts are worked in series and alternate ways of working are described. Chloride of zinc can be substituted by any other chloride or metal which is not affected by hydrochloric acid or ammonia vapour. In place of oxide of manganese other oxides may be used.

—H. A.

*A New or Improved Process for the Recovery or Regeneration of Nitric Acid Employed in the Manufacture of Chlorine.* W. Wolters, St. Petersburg, Russia. Eng. Pat. 16,609, October 21, 1889. 4d.

THE weak point in the manufacture of chlorine by the action of hydrochloric acid and nitric acid on manganese is the recovery of the nitric acid, considerable quantities of which are lost in calcining the nitrate of manganese liquor and in the subsequent conversion of the hyponitric acid vapours into nitric acid, by means of air and water. It is proposed to distil off the excess of nitric acid from the still liquor, using the weaker fractions for condensing the hydrochloric acid used in the process, and the stronger fractions, along with air, for the conversion of the hyponitric acid set free in the decomposition of the residual “nitrate of manganese sesquioxide” with steam or air.—H. A.

*Improvements in the Manufacture or Production of Cyanide Compounds from Ferro-Cyanide Compounds.* E. Bergmann, Hamburg, Germany. Eng. Pat. 4095, March 15, 1890. 6d.

THIS invention effects (1) the manufacture of cyanides by the action of silver or copper salts in dilute solution on ferrocyanides, which are dissolved or suspended in boiling water. The silver or copper taking part in the reaction should be sufficient to combine with the whole of the cyanogen present; and a small quantity of free acid is requisite to further the reaction—

When eupric salts are used, it is necessary to add a reducing agent, such as sulphites,  $\text{SO}_2$ , &c. to promote the reaction—

(2) the cyanide of silver or copper obtained by any of these reactions is available for the manufacture of double salts, in digesting them with sulphides of the alkalis or alkaline earthy metals, or with an alkaline ferrocyanide—

(3.) In the former reaction the solution of copper-barium cyanide can be utilised for the manufacture of other double salts. The copper ferrocyanide produced in the latter equation is available for manufacturing new quantities of cyanide of copper, as given above.—H. A.

*A New or Improved Process for Manufacturing Bleaching Powder and Caustic Soda.* J. D. Pennock and J. A. Bradburn, Syracuse, U.S.A. Eng. Pat. 8090, May 23, 1890. 4d.

THE object of this invention is the regeneration of the nitric acid employed in manufacturing chlorine, and the utilisation of the nitrate of soda obtained therein for the manufacture of caustic soda.

Salt and nitric acid are introduced in a still, and on heating the whole of the chlorine of the salt is given off as a mixture of nitrosyl chloride and chlorine, which is converted into

pure chlorine by passing it through nitric acid, holding dioxide of manganese in suspension; nitrate of manganese is obtained thereby as a by-product.

The hot still liquor, consisting of a saturated solution of nitrate of soda, undecomposed salt, and nitric acid, is run off: half of the nitre is deposited on cooling, and the mother-liquor used over again for a new batch. The nitre so obtained is available for the manufacture of caustic soda, for which purpose it is furnaceed at a moderate red heat with 2—3 times its weight of oxide of iron in a current of air. In lixiviating the resulting mass with hot water, a solution of caustic soda of a density of 50°—77° Tw. is obtained.

The nitric acid introduced in the process is regenerated by passing the hot waste gases from the revolver first over an oxidising substance ( $MnO_2$ , manganites, manganates, permanganates), and afterwards over the nitrate of manganese solution obtained in the washing of the chlorine, which is evaporated down to a plastic condition, when  $MnO_2$  will remain, and the nitrous compounds are condensed as nitric acid after the usual treatment with air and steam.—H. A.

*Improvements in Apparatus for the Condensation of Nitric Acid and other Distillation Products.* O. Guttman, London. Eng. Pat. 8915, June 9, 1890. 6d.

THE condensation is effected by passing the vapours through one or more series of vertical earthenware pipes, connected on top and bottom by means of bends, the bottom bends being provided with traps and branch pipes, which lead in one main and a common receiver. The acid is condensed by surface cooling and collected continuously from each bend. The undecomposed acid passes from the last earthenware pipe through a coke tower, as usual.—H. A.

*Improvements relating to the Manufacture of Acid Phosphates for use as Artificial Manure.* H. H. Lake, London. From A. Memminger, Charleston, U.S.A. Eng. Pat. 9129, June 12, 1890. 4d.

IN the usual way of manufacturing superphosphates, the finely-ground phosphatic rock is mixed with the requisite quantity of sulphuric acid of 50° B. and allowed to dry. The duration of the drying operation depends greatly on the quality of the rock, and the object of this invention is to reduce the time of drying and thus to make phosphates of any origin suitable for the manufacture of superphosphates.

This is effected by an addition of about 5 per cent. or more of fluor spar to the rock, grinding the two materials together to pass through a 40-mesh sieve.—H. A.

*Improvements in the Packing or Putting-up of Chloride of Lime and other Substances.* T. C. Steele, Glasgow. Eng. Pat. 9670, June 21, 1890. 4d.

THE package is made of paper, cardboard, or thin wood, and rendered gas- and water-tight by dipping it in molten wax, or a mixture of the same with rosin, pitch, gums, or drying oils.—H. A.

## VIII.—GLASS, POTTERY, AND EARTHENWARE.

*Alteration of the Coefficient of Compressibility of Glass at different Temperatures.* E. H. Amagat. Compt. Rend. 110, 1246—1249.

THE author has been led to determine the coefficient of compressibility of both ordinary soda- and lead-glasses at various temperatures by the need for accurate knowledge of possible alterations, as demonstrated by his own researches, and the conflicting statements current on the subject. The problem was attacked by observing the alterations in volume of a long glass cylinder subjected to high pressure at known temperatures. Among the difficulties encountered was the tendency of the cylinder to act as an ultra-sensitive thermometer, if made large, so as to give measurable readings, while the use of a small cylinder necessitated such high pressures that permanent deformation was apt to result. The instrument adopted consisted of what was practically a piezometer enclosed in a steel cylinder filled with mercury, which was jacketed, so that the intermediate annular space could be filled with ice, steam, or the vapour of methyl benzoate (boiling point 200° C.), according to the temperature needed. The readings of the instrument were regulated so that they ranged over a comparatively short scale (to avoid error due to imperfect calibration), which was kept at a constant temperature by a water jacket.

The following table shows the results obtained; the numbers are arbitrary, representing divisions on the scale.

Temperature.	Piezometer No. 1. (Glass.)		Piezometer No. 2. (Glass.)		Piezometer No. 3. (Flint Glass.)	
	Divisions on the Scale.	Alteration per 100 Divisions.	Divisions on the Scale.	Alteration per 100 Divisions.	Divisions on the Scale.	Alteration per 100 Divisions.
0	202.7	2.95	205.7	2.71	182.8	4.10
100	208.7		211.3		190.3	
200	215.5		218.6		203.0	

The increase in the variation with rise of temperature is here manifest; it is quite appreciable for ordinary glass and distinctly greater for flint glass. It is in all cases somewhat higher than the value arrived at by Guillaume in his work on thermometers of precision, but the instruments he used were of hard glass. Although the existence of this variation

is thus well established, it is in any case extremely small, and would generally be negligible. Thus, the error experienced in estimating a volume at 200° C. under a pressure of 1,000 atmospheres would be only 0.00028 if this correction were ignored.—B. B.

## IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

*Manufacture of Slag Cement.* J. Grosclaude. Dingl. Polyt. J. 275, 433—445.

THE trade in slag cement has recently grown considerably and its manufacture is now practised both in England and abroad. Besides being sold under its proper name it sometimes come into the market under the inappropriate titles of puzzolana and Portland cements. In the first place it is necessary to distinguish it sharply both from Portland cement proper, and from untreated slag often used as a sophistication for hydraulic cements. Slag cement is of the puzzolana order, *i.e.*, it is a mixture of active siliceous matter and lime which unite and set on the addition of water; the active siliceous matter is ordinary blast-furnace slag granulated and ground to bring it into a suitable condition and the lime is the ordinary substance carefully slaked. Taking the raw materials and their treatment systematically we have:—

(1.) *Granulation of the Slag.*—This is effected by quenching the molten slag with water and is absolutely essential for the production of a cement of any value; the precise change is not well understood. It may be regarded as analogous to the change produced in sulphur by fusing and quenching it where an altered molecular condition is preserved by sudden cooling; in this case the less complex molecule formed at a higher temperature would be prevented

from aggregating as it would were the cooling slow and retained in the same state when cold. A contrary hypothesis may be advanced to the effect that combinations existing at the higher temperature are decomposed by quenching and thus resolve themselves into simpler substances. In either case there is little doubt that granulation produces a state of greater molecular simplicity and activity, rendering the double silicate of lime and alumina constituting blast-furnace slag, active and capable of playing the same part that puzzolana does in cements made from that substance.

(2.) *Composition of the Slag.*—Besides its molecular condition, the ultimate composition of the slag is of great importance. Experience has shown that the oxygen of the silica, together with that of the alumina, should have to that of the lime approximately the relation 2:1. *Tetmajer*, who has worked considerably at the subject, is of opinion that a slag in which the relation of lime to silica is lower than unity—

$$\left( \frac{\text{CaO}}{\text{SiO}_2} < 1 \right)$$

is not available for cement making. He fixes the best composition as: lime 46, silica 30, alumina 16. Certain slags contain a notable proportion of calcium sulphide. Some of this is decomposed on granulation, but enough remains as a rule to give the cement a greenish colour due to the trace of iron present when allowed to set in water or damp air. It does not appear, however, that any harmful action can be ascribed thereto. The following table exhibits the composition of a few typical slags:—

—	Marnaval.	Saulnes.	Choizeux.	Hartzburg.	Middlesbrough.	Bilbao.
CaO .....	48.00	47.20	45.11	48.59	32.26	47.30
SiO <sub>2</sub> .....	30.50	31.65	26.88	30.72	31.65	32.90
Al <sub>2</sub> O <sub>3</sub> .....	19.50	17.00	24.12	16.40	25.30	13.25
FeO .....	0.85	0.65	0.44	0.43	0.10	0.46
MgO .....	0.75	1.36	1.09	1.28	3.54	1.37
CaS .....	..	..	1.86	2.16	1.42	3.42
MnO .....	0.40	0.85	0.50	Trace	0.36	1.13
Undetermined .....	..	1.29	..	0.42	5.37	0.17
	100.00	100.00	100.00	100.00	100.00	100.00

(3.) *Slaking the Lime.*—The common plan is to dip the lime contained in baskets bodily into water, but a preferable method is to use a special apparatus consisting of cylindrical vessels, in which the lime in pieces about the size of an egg is placed, enclosed in an outer cylindrical case fitted with a pressure gauge and safety valve. The whole being closed, water is admitted by sprinklers and the slaking goes on regularly, the lime being exposed to an evenly damp atmosphere, while at the same time local excess of water is avoided inasmuch as any volatilised during slaking falls back into the space between the vessel containing the lime and the outer cylinder, and does not drop back direct on to the lime itself. A pressure of 5—6 atmospheres is generally reached.

(4.) *Drying the Granulated Slag.*—Several methods have been proposed; the most obvious, *viz.*, exposing the slag, spread out in layers 6—7 cm. deep to flue gases, permits an output of 100 kilos. per sq. metre in 24 hours, with an expenditure of 6—7 kilos. per centner of dried slag.

*Ruelle* has devised an ingenious arrangement consisting of a long slightly tapering drum, capable of being rotated, within which is a screw by which the slag is carried from the end where it is fed into that nearer the furnace, the drying being thus systematic. Surrounding this drum is another coned in the reverse direction, and also provided with a screw, so that the dried and heated slag is gradually

carried back to the end whence it started, imparting its heat to the inner drum during its passage.

Such an apparatus will turn out about 25 tons of dried slag in 24 hours, with a coal consumption of 6 kilos. per 100 kilos. of dried product, and an expenditure of 6—7 horse power.

*Raty* has made an attempt, worth recording, to dispense with the necessity for such drying apparatus. He quenches the slag, with precaution, so as to avoid leaving any part semi-fused or plastic, while at the same time as nearly as possible the whole of the water is volatilised. Any final drying necessary is effected by passing molten slag through a pipe buried in a heap of the granulated product.

(5.) *Grinding the Granulated Slag.*—This is effected in an ordinary edge-runner, which, though rather wasteful of power, is best fitted for this particular purpose.

(6.) *Mixing the Slag and Lime.*—A mill, consisting of a cylinder with its inner surface shaped into a series of depressions and elevations and containing a number of iron balls, is used. The mingling is very perfect, while the fineness of the finished product may be gathered from the fact that it leaves a residue of 8—10 per cent. on a sieve of 5,000 meshes per sq. cm.; on the attainment of this degree of fineness, much of the quality of the cement depends.

The lime used is generally an ordinary "fat" lime, but it seems likely that a poorer lime would be better, there being less risk of the cement cracking if used in air.

It sometimes happens owing to the composition of the slag being not quite suitable that cement made from it sets badly and shows cracks and a tendency to disintegrate.

These evils may be overcome by mixing a little precipitated silica and alumina with it, the former being prepared by treating a portion of the slag with hydrochloric acid, while the latter may be obtained by precipitating the filtrate from the silica with lime.

(7.) *Strength of Slag Cement.*—The results about to be given are taken from the publications of the *Écoles des Ponts et Chaussées* (No. 3405, September 7, 1888), and refer to a cement made at the Donjeux factory from Marnaval slag and "fat" lime. The composition of the cement was:—

Sand .....	0.25
Silica .....	23.85
Alumina .....	13.95
Ferric oxide .....	1.10
Lime .....	51.40
Magnesia .....	1.95
Sulphuric anhydride .....	0.45
Loss on ignition .....	7.05
	<hr/> 100.00

When sifted it left on a sieve of 324 meshes per sq. cm., 0.7 per cent. residue, on 900 meshes 0.8 per cent., and on 5,000 meshes 21.5 per cent., the total residue amounting to 23 per cent. When gauged with 28 per cent. of water, it began to set in  $1\frac{1}{4}$  hours, and setting was complete at the end of 3 hours.

The following table shows the mean results of the mechanical tests:—

	In Tension.			In Compression.		
	Kilos. per sq. cm.			Kilos. per sq. cm.		
	7 Days.	28 Days.	84 Days.	7 Days.	28 Days.	84 Days.
Neat cement .....	21.87	26.88	31.15	275.7	377.3	462.3
Cement + Sand .....	14.93	26.03	29.23	180.0	260.2	319.2
(? 1:3)						

It must be admitted that this is about the best sample, the behaviour of which is recorded in the paper above mentioned, but it serves to show what quality may be attained. It has been alleged that slag cement fails when used for sea work, but it has been used for harbour work both at Bremen and Middlesbrough.

In judging a slag cement from the analytical data it affords, it must be remembered that the criteria of excellence that are in vogue for Portland cement do not apply to it.

Thus a good Portland cement of low specific gravity is almost a contradiction in terms, whereas a good slag cement may have quite a small density.

A detailed statement of costs for erecting the necessary plant and carrying out the manufacture are given in the original.—B. B.

## X.—METALLURGY.

*The Dry Assay of Tin Ores.* Part 1. H. O. Hofman. *Technical Quarterly*, 3, 112—143.

See under XXIII., page 899.

*The Estimation of Phosphorus in the "Basic" Siemens Steel Bath.* W. Galbraith. Paper read before the Iron and Steel Institute, May 1890.

It is usual to judge of the extent to which the oxidation of the phosphorus has proceeded by withdrawing a sample, hammering down, quenching in water and examining the fracture, which should be bright and crystalline and have a characteristic streaky appearance if the phosphorus be present in quantity. The appearance is apt to vary, however, with the size of the sample, the amount of hammering and the temperature at which it is quenched. The following chemical test is rapid and more reliable: 0.20 grm. of the drillings are dissolved in 3 cc. of aqua regia in a small flask, 3 cc. of water are added and enough ammonia to precipitate the whole of the iron. The precipitate is next dissolved in nitric acid added drop by drop until the liquid is distinctly clear. 10 drops of ammonium molybdate, prepared according to Fresenius, are then added, the liquid is transferred to a small bottle 2 in. high by  $\frac{1}{2}$  in. in diameter, diluted to a mark on the bottle and well shaken. Similar operations conducted with a standard steel containing say .05 per cent. of phosphorus, and the opacities were compared. The comparison becomes more simple if a series of bottles be prepared containing from .01 per cent. to .10 per cent. of phosphorus. The molybdic solution is made by dissolving 50 grms. of molybdic acid in a mixture of 100 cc. of ammonia and 100 cc. of water and pouring the liquid into 750 cc. of nitric acid (sp. gr. 1.20). It is not advisable to arrest a basic Bessemer blow sufficiently long to allow of this test being made, but the analysis may easily be performed between each blow and any phosphoric heat detected.—H. K. T.

*Aluminium in Carburetted Iron.* W. J. Keep. Paper read before the Iron and Steel Institute, May 1890.

THE author first describes the method used by him in making mechanical tests, he then gives the effect of aluminium on various kinds of iron and steel. With commercially pure iron in the form of Robert-Bessemer ingots, the addition of 0.25 per cent. of aluminium diminishes deflection by decreasing the set and elasticity. Rigidity is increased, the grain is closer and more uniform, and the metal is improved as a structural material. Remelted wrought iron containing 2.45 per cent. of aluminium makes a good weld and after being forged can be bent nearly double. Its grain is like that of fine steel. Wrought iron with the above percentage of aluminium can be easily cast. With a higher percentage of carbon, as in steels, aluminium slightly increases the hardness, owing to some of the graphite being expelled, since, with low percentages of carbon, aluminium does not convert the combined carbon into graphite, but expels some of the existing graphite. White cast iron is greatly improved by aluminium since the carbon is reduced in amount and part of it is converted into graphite, thus lessening the hardness of the metal and increasing its rigidity and elasticity. The author points out that if the graphite of grey cast iron could be produced by aluminium instead of by silicon the metal would be better for most purposes. Even at the present price of aluminium the addition is generally advantageous (compare this *Journal* 1888, 752).—H. K. T.

*Certain Chemical Phenomena in the Manufacture of Steel.* W. Galbraith. Paper read before the Iron and Steel Institute, May 1890.

IN the manufacture of soft steel either by the Bessemer or Siemens process, especially where a basic lining is used, there is often experienced a difficulty in keeping the metal

quiet in the mould. This is usually accompanied by a difficulty in teeming, a considerable quantity of metal being left in the ladle. The author considers that these difficulties are due to oxide of iron disseminated through the metal, especially as they are accompanied by a metallic-looking slag high in iron, by a large evolution of gas, and by an excessive consumption of spiegeleisen or ferro-manganese before the carbon can be increased. In support of this view it frequently happens that metal will teem badly whilst showing nothing abnormal on ordinary analysis, whilst on the other hand the effect of an oxidising slag in rendering steel infusible is well known. In further support of his view the author quotes Müller's experiments on the secretion of gases in iron and steel (Iron, September 14, 1883), in which it was found that basic steels contain an abnormal amount of carbonic oxide, the latter being produced at the expense of the oxides in the metal when the oxidising slag was removed. Another effect of a slag containing much oxide of iron is that the iron is oxidised more rapidly in proportion to the amount of phosphorus removed. In order to avoid the injurious effect of the basic slag on the spiegeleisen and to obtain a better control of the carbon in the metal, the steel after teeming is run into a second ladle until the basic slag begins to come, when the stream is stopped, at the same time some siliceous slag, similar to ordinary Siemens slag, together with the necessary alloys, is added.—H. K. T.

#### *Steel Rails considered Chemically and Mechanically.*

C. P. Sandberg. Proc. Inst. Mech. Eng. July 29, 1890. Industries, 9, 97—101.

The subject is discussed and tabulated analytical data given, under the following headings:—

Safety and durability.

Favourable effect of silicon.

Experiments on high silicon steel rails.

Hardness dependent on carbon and phosphorus.

Heavier and harder rails for safety.

The remaining headings have no direct connexion with applied chemistry.

*The Critical Points of Iron and Steel.* F. Osmond. The Iron and Steel Institute, May 1889. (See also this Journal, 1890, 517—518.)

The paper dealt with experiments carried out for the examination of the rate of cooling of samples of iron and steel of different composition with a view to determine their critical points.

The samples operated upon were in the form of bars, into one end of which one of the junctions of Le Chatelier's thermo-electric pyrometer (Journal de Physique, VI, Jan. 187) was soldered. The couple of the latter was composed of a cast platinum and a platinum-iridium wire, and the opposite ends were connected with a Deprez and D'Arsonval aperiodic mirror galvanometer.

The pyrometer was calibrated by means of the melting point of potassium sulphate (1,015°) and the boiling point of ammonium chloride (340°), and it was assumed that the temperatures, up to 1,500°, were proportional to the electromotive forces of the couple. In experimenting, the metallic bar, with wires attached, was placed in a porcelain tube closed with corks and heated to the required temperature. The furnace and tube were then allowed to cool spontaneously and the times at which the index passed each division of the scale were recorded by means of a chronograph. The temperatures were then plotted as abscissæ, and the times included between the passage of the index over two consecutive divisions of the scale as ordinates. The different critical points are indicated by the letters  $a_1$ ,  $a_2$ ,  $a_3$ , &c. —  $a_1$  representing the lowest temperature.

The first experiments were made on samples of iron and steel with increasing proportions of carbon, the other constituents remaining, as far as possible, constant. The following table gives the nature and composition of the different samples:—

	Electrolytic Iron.	Extra Mild Steel, basic Open-Hearth.	Mild Steel, basic Bessemer.	Fairly Mild Steel, acid Open-Hearth.	Hard Crucible Steel.	Swedish White Pig Iron.
Carbon.....	0.08	0.160	0.290	0.570	1.250	4.100
Silicon.....	..	0.012	0.060	0.085	0.190	0.220
Sulphur.....	..	0.021	0.060	0.020	0.010	0.040
Phosphorus.....	..	0.029	0.052	0.050	0.021	0.018
Manganese.....	..	0.110	0.270	0.230	0.100	0.120

The following arrests were obtained:—

	$a_3$ .	$a_2$ .	$a_1$ .
Electrolytic iron..	885° (abrupt and very long).	750°—690° (very gradual).	660° (almost imperceptible).
Extra mild steel..	845°—800° (gradual).	755°—710° (gradual).	680°—645° (gradual).
Mild steel.....	780°—690°		680°—640°
Fairly mild steel..	750°—661°		661°
Hard steel.....	860° (very slight).	..	674° (very long).
White pig iron....	..	..	695° (short).

The above results show that the delay in cooling  $a_1$ , which is almost imperceptible in electrolytic iron, goes on increasing with the proportion of carbon until it assumes enormous proportions in hard steel. Thus it is a function of the proportion of carbon, and is identical with the phenomenon discovered by Barrett in 1873, and named by him "recalcence."

The station  $a_1$ , which increases in duration with the proportion of carbon in steels, diminishes on passing from

hard steel to white pig iron, hence there is little change of state at this point, and the carbon at all temperatures is either in the form of hardening carbon or of cement carbon. With regard to the other points of rest in electrolytic iron, there is a sudden arrest,  $a_3$  at 855°, and a more gradual one,  $a_2$ , at 750°—690°. In extra-mild steel the same stations are observed,  $a_2$  remaining the same,  $a_3$  being somewhat lowered. In mild steel,  $a_3$  is still lower, and becomes confounded with  $a_2$ , so that there is a single gradual slackening,  $a_3-2$ . In medium steel, the point  $a_3-2$  continues to descend and joins on to  $a_1$ . Finally, in hard steel, the three critical points are merged into one, and  $a_3-2-1$  at 674°.

The point  $a_3$ , since it is most distinct in pure iron, probably represents a change of molecular state of the element, the change being analogous to that which is known to take place in the case of sulphur, silicon, &c. The point  $a_2$  may represent a distinct molecular modification of iron, but as it is not sharply defined, even in electrolytic iron, the author preferred to regard it provisionally as the end of  $a_3$ . Thus, below  $a_2$ , iron possesses the molecular form  $\alpha$ , whilst above  $a_3$  it assumes the allotropic form  $\beta$ . At intermediate stations it is a mixture of  $\alpha$  and  $\beta$ . The action of carbon on iron can now be easily summarised. Carbon, in the form of hardening carbon, maintains iron in the  $\beta$  condition, during slow cooling, down to a temperature which is lower

the greater the quantity of carbon present. The points  $a_3$ ,  $a_2$ , and  $a_1$  correspond with a number of changes already observed in the physical properties of iron, such as recalcence, variation in specific heats, appearance and disappearance of magnetism, and changes in rate of dilatation and electrical resistance.

**Influence of the Initial Temperature and of the Rate of Cooling on the Position of the Critical Points. Theory of Hardening.**—If samples be cooled from successively higher temperatures it is found that the temperature of recalcence is proportionally lowered. The temperature of recalcence is also lowered the more rapid the cooling. If the sample is cooled in water no retardation is observed. Thus, if the cooling is fairly rapid the changes produced during slow cooling do not take place, and the hardened steel consists of iron and carbon in the state in which they existed at high temperatures. In order to see if the heat which had not been evolved was really latent in the steel, equal weights of annealed and hardened steel were dissolved in the double copper ammonium chloride. The following rises in temperature were obtained:—

	Annealed.	Hardened.
Medium steel .....	2°366	2°477
Hard steel .....	2°148	2°369
White pig iron .....	1°665	1°878

Hence the hardened metal contains an excess of heat over the annealed one. The influence of time on the change of state during cooling is in accord with general chemistry.

With regard to the share of iron and carbon in communicating the usual properties of hardened steel to the metal, the author considered that they are mainly due to the iron and that hardened steel contains the iron in the  $\beta$  condition. In order to prove this, steel was hardened at a temperature between  $a_3-2$  and  $a_1$  that is, at a temperature at which the change (during cooling) of iron from the  $\beta$  state to the  $\alpha$  is well advanced, whilst the combination of the carbon with the iron has not yet commenced. The metal so obtained was soft under the file, yet when treated with nitric acid it gave the reaction for hardening carbon. On the other hand mild steel may be hardened by heating to a temperature above  $a_3$ , and rendering the cooling from this point extremely rapid by plunging the metal into a freezing mixture. Under these circumstances the tensile strength increases from 26·6 tons to 61·5 tons per square inch, the elongation decreasing from 30 to 4 per cent. This enormous diminution in malleability could not be due to the ·22 per cent. of carbon which the steel contained, but is due to the iron being in the  $\beta$  condition. The influence of carbon is the same as that of rapid cooling, and hinders the conversion of iron from the  $\beta$  to the  $\alpha$  condition.

**Phenomena observed on heating the same samples between 600° and 1,100°.**—On heating samples of iron and steel the same critical points were observed as on cooling, but they were uniformly lower. The difference in  $a_3$  for heating and cooling is least in electrolytic iron. These considerations explain the fact observed by Brinell that the temperature to which steel must be heated to enable it to be hardened and the temperature at which it suffices to cool it, are not identical.

**Heating and cooling below 600°. Theory of Tempering.**—Annealed steel does not show any critical points below 600°. Hardened steel on heating begins to evolve heat at 200°, so that there is an acceleration in the rate of heating when this temperature is reached. The maximum liberation of heat is reached at 350°, and it ceases at 520°. A further evolution of heat occurs at 660°—680°. Hence the iron and carbon in hardened steel are in a state of unstable equilibrium similar to that of plastic sulphur, and during tempering the  $\beta$  iron returns to the  $\alpha$  state and the hardening (uncombined) carbon to the condition of iron carbide.

**Influence of Foreign Metals. Boron.**—A sample from Roberts-Austen was examined. There were two liberations of heat, viz.,  $\frac{a}{m} r_3$  of which the maximum is produced between 815° and 805°;  $a r_2 + \frac{(m-1)a}{m} r_3$  of which the maximum is produced between 738° and 725°, each station being lowered. The two liberations of heat are fairly equal. This action is analogous to that of carbon.

**Nickel.**—The sample showed a single station,  $a_3-2-1$ , at 650°. In a steel containing the same amount of carbon,  $a_1$  would be quite distinct; thus, the nickel has considerably lowered the charge of iron and of carbon.

**Manganese.**—The temperature of the allotropic change of iron and of recalcence is lowered in proportion as the percentage of manganese is increased. Ferro-manganese only shows traces of arrestation. Thus manganese has the same effect as carbon in maintaining the iron in the  $\beta$  condition. In ferro-manganese and highly manganiferous steels all the iron is in the  $\beta$  condition, a condition similar to that of iron at a temperature above 860°. This explains why these alloys are not magnetic, since iron above 860° cannot be magnetised.

**Copper.**—The samples were prepared by Dr. Edwin J. Ball and Mr. Arthur Wingham (Jour. Iron and Steel Inst. 1889, 123). With 0·847 per cent. of copper the three points,  $a_3$ ,  $a_2$ , and  $a_1$  are quite distinct, but  $a_3$  is lowered some 40 or 50 degrees. With a greater proportion of copper,  $a_3$  becomes confounded with  $a_2$ , and  $a_1$  descends. The effect therefore of copper is the same as that of the previous metals but it is not so energetic, 4 per cent. of copper having the same effect as 0·2 per cent. of carbon.

**Chromium.**—Three samples were examined with 1·0, 2·0, and 10—12 per cent. of chromium. With the first the maximum  $a_3-2$  is slightly higher than with steel containing the same amount of carbon. The remaining two samples, cooled from 1,100°, show only one perturbation  $a_3-2-1$  in the form of a highly accentuated recalcence. The third sample cooled from 800°; recalcenes at the exceptionally high temperature of 744°. Hence it appears that the effort of chromium is to raise the critical point  $a_1$  and its action is of an opposite nature to that of manganese, and is equivalent to annealing. If chromium steels unite in a remarkable manner certain opposite properties and are but slightly brittle in proportion to their hardness, we must assume that their hardness is due to the chromium itself, and their consistency to the absence of  $\beta$  iron. The influence of the initial temperature on the portion of  $a_1$  is greater in chrome steels than in carbon steels.

**Tungsten, 0·26 to 1·53 per cent.**—The points  $a_3$  and  $a_2$  retain their original positions, but  $a_1$  is lowered to 530°. Thus tungsten has no action on the change of iron per se, but it has a hardening action through the agency of the carbon which it has a tendency to retain in the form of hardening carbon. This action is peculiar to tungsten. The lowering of  $a_1$  only takes place when the initial temperature is sufficiently high. If cooled from 750°  $a_1$  appears at 670°.

**Silicon.**—The samples were supplied by Mr. Hadfield, and consisted of an extended series in which the silicon was the only variable (Iron and Steel Institute, September 1889). With increase of silicon  $a_3$  is raised and approaches its position in pure iron. It eventually disappears altogether and is not found even when the metal is heated to 1,400°. Hence the effect of silicon is to keep the iron in the  $\alpha$  condition.

**Arsenic.**—The effect of this element is similar to that of silicon in tending to raise  $a_3$  and to diminish its intensity;  $a_2$  and  $a_1$  are not affected.

**Phosphorus.**—Two samples were examined, a sample of puddled iron ( $P=0\cdot38$  per cent.) and one of basic Bessemer metal (before afterblow,  $P=1\cdot35$  per cent.). The curve for the puddled iron is exactly similar to that of electrolytic iron,  $a_3$  being gradual and not abrupt. Probably in this sample the phosphorus was chiefly in the form of phosphate

of iron. The Bessemer metal gave only one very indistinct point ( $a_1$ ) at  $680^\circ$ . The effect of phosphorus is therefore similar to that of silicon.

**Sulphur.**—A single sample of basic Bessemer steel (S=0.28 per cent.) was examined and its curve compared with that for a steel containing the same amount of carbon and manganese. The stations  $a_{3-2}$  and  $a_1$  were found to be raised. The action of sulphur appears to be similar to that of silicon and phosphorus.

**General Conclusions on the Influence of Foreign Elements.**—Roberts-Austen has found that the effect of foreign elements on the properties of gold is related to the periodic classification (Phil. Trans. 179, 339–349). The author finds that a similar relation holds in the case of steel. Thus in general those elements the atomic volumes of which are less than that of iron, delay during cooling, the change of  $\beta$  iron (hard) into  $\alpha$  iron (soft), and that of hardening carbon into carbide. They therefore have a hardening action. (To this class belongs hydrogen, since electrolytic iron is very hard and brittle.) On the other hand, those elements the atomic volumes of which are greater than that of iron, tend to raise the change of the iron to the normal position which it occupies in pure iron. They hasten during cooling the combination of the carbon with the iron, and retard the inverse change during heating. They therefore communicate softness and malleability. In other words, elements of low atomic volume tend to maintain the iron in the form in which it has itself the lowest atomic volume, and conversely. The magnetic properties of iron are subject to the same influence, those elements the atomic volumes of which are less than that of iron increasing the permanent magnetism of the iron, whilst those the atomic volumes of which are greater, have no action on the permanent magnetism.—H. K. T.

#### PATENTS.

*Improvements in the Treatment of Refractory Gold and Silver Ores and in Apparatus therefor.* H. Hutchinson, London. Eng. Pat. 16,270, November 26, 1887. (Second Edition.) 8d.

Previously described (this Journal, 1889, 287).—A. W.

*Improvements in Coating or Plating Metal Plates or Articles of Large or Small Size.* W. P. Thompson, Liverpool. From A. A. L. Levy, Paris, France. Eng. Pat. 12,556, August 8, 1889. 6d.

This is a claim for the coating of any metal with another metal by simple immersion of the former in a solution of the chloride of the latter mixed with chloride of ammonium. The presence of the latter salt is the "essential foundation" of the process.—A. W.

*Improvements in Treating Liquid Acid Residues containing Iron to obtain Products therefrom.* M. N. d'Andria, Manchester. Eng. Pat. 13,575, August 28, 1889. 4d.

See under VII., page 860.

*An Improved Process for Recovering Valuable Substances from the Mother-Liquors Resulting from Treatment of Copper Ores.* E. de Cuyper, Perennes-lez-Binche, Belgium. Eng. Pat. 13,726, August 30, 1889. 8d.

See under VII., page 860.

*An Improvement in Foundry Sand.* J. Patriek, Frankfurt-on-Main, Germany. Eng. Pat. 14,408, September 12, 1889. 4d.

The patentee mixes with the sand, coal-tar, asphalt, bitumen, or a similar viscous body. Five parts of tar are liquefied by

heat, stirred into five parts of hot water and the mixture poured on to 100 parts of sand. It is maintained that by this means sand which is either too fine or too coarse for cores or moulds is rendered suitable, the former by having its porosity increased and the latter by an increase in its density and cohesion.—A. W.

*Improvements in Metallurgical Furnaces.* C. A. Piat, Paris, France. Eng. Pat. 18,985, November 26, 1889. 8d.

This is an arrangement in which a small cupola is placed over a crucible furnace in such a way that the waste gases from the latter can be utilised in assisting the heating of the former. Neither furnace is a fixture. The cupola is adapted to a hollow bearing, through which the air is supplied, in such a manner that it can be slightly raised from the crucible furnace and swung round out of the way, while the latter, which is held on one end of a counter-balanced rocking beam, is raised to discharge its contents. The cupola is so arranged that it can be used by itself simply as a cupola or in conjunction with the crucible furnace.—A. W.

*Improved Manufacture of Compositions or Alloys for Anti-Friction Purposes.* E. C. Miller, London. From The Magnolia Anti-Friction Metal Co., New York, U.S.A. Eng. Pat. 8655, June 4, 1890. 4d.

The ingredients are the following:—

Lead.....	80 lb.
Antimony.....	15 "
Tin.....	5 "
Bismuth.....	4 ounces.
Graphite.....	8 "

and according to the desired quality of the alloy—

Silver.....	4 ounces.
or Aluminium.....	4 "

The lead is melted and cleaned with sal-ammoniac, the antimony added, the graphite then stirred in and the tin and bismuth mixed in last. When desired silver or aluminium can be incorporated. The alloy is recommended for shaft bearings.—A. W.

## XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

*On the Electro-deposition of Platinum.* W. H. Wahl. J. Frank. Inst. 130, 1890, 62–75.

THE author points out the great demand that exists for a good and reliable process for producing a bright and adherent deposit of platinum, and mentions that, of all the methods that have been proposed, only three deserve special notice. These are: (1.) The Roseleur-Lanaux method, based on the electrolysis of a solution of the double phosphate of sodium and platinum. (2.) The process of the Bright Platinum Plating Company (London), a modification of that of Roseleur, involving the introduction into the bath of certain substances, such as sodium chloride and borax, to ensure a bright deposit of the metal; and (3.) Boettger's method, founded on the electrolysis of a solution of the double chloride of ammonium and platinum in sodium citrate. These processes give good results at the commencement, but the solutions deteriorate from a variety of causes, the chief among which is the insolubility of platinum as an anode, which necessitates occasional additions to the baths of fresh quantities of the platinum salt, whereby the electrolytes are continually altering in conductivity, and gradually becoming contaminated with secondary products. The character of the deposit of platinum is naturally impoverished by such alterations in the conditions.

All the solutions recommended for electro-plating, except Boettger's, are made by treating the platonic chloride with alkaline salts, the most favoured of which are the phosphates and oxalates. The result is a solution of the double phosphate or oxalate, as the case may be, together with the chloride of the alkali from the decomposition of the platonic chloride. As the solution becomes impoverished it is strengthened by fresh additions of platonic chloride, with the result that the alkaline chloride accumulates, until the bath is practically spoilt. Boettger maintains his bath by fresh additions of the original solutions, but here again the accumulation of foreign substances must follow. The author then describes his own experiments on the subject with a view to remedy these defects.

Platinum black deposited on carbon was used as an anode, in the hope that a large surface would facilitate the solution of the metal, but it was found to be impractical, as the solution had to be strongly acid, and the current of such a strength that only a black and non-adherent deposit was obtained. Again, it was quite useless with those solutions which give the best deposits, that is, the phosphates and oxalates. A solution of platonic hydrate in caustic potash was found to give a good deposit of metal, and the bath could be kept up to standard by additions of the platonic hydrate without any deterioration due to the accumulation of foreign salts. The author recommends the use of platonic hydrate in the preparation, and the maintenance of the strength of the ordinary solutions in use, and gives the following directions:—

#### *The Alkaline Platinate Solution.*

Platonic hydrate.....	2 oz.
Caustic potash .....	8 oz.
Distilled water .....	1 gall.

One-half of the caustic potash is dissolved in a quart of water and the platonic hydrate gradually added; when solution is effected, the remainder of the caustic dissolved in another quart of water, is stirred in, and the solution made up to a gallon. A current of about 2 volts is the best, and there should be only a slight, if any, evolution of hydrogen at the cathode, but a liberal one of oxygen at the anode. The solution may be worked at half the above strength. A little acetic acid improves the working of the bath when a heavy deposit is required. Articles of steel, nickel, tin, zinc, or German silver are preferably first thinly coated with copper in a hot cyanide bath.

The oxalate solution is prepared by dissolving 1 oz. of platonic hydrate in 4 oz. of oxalic acid, and diluting to one gallon. The best plan is to work with a saturated solution of the oxalate, keeping an undissolved excess always present. The addition of a small quantity of oxalic acid now and again is advantageous. The double oxalate may be prepared by saturating the alkaline oxalate with platonic hydrate, the strength of the bath being maintained by the presence of the single oxalate, as above. The deposits from these solutions are sensibly harder than that obtained with the alkaline bath, and will buff tolerably well.

#### *The Phosphate Solution.*

Phosphoric acid, syrupy (sp. gr. 1.7).....	8 oz.
Platonic hydrate .....	1-1½ oz.
Distilled water .....	1 gall.

The acid should be moderately dilute, and the solution of the hydrate effected at the boiling temperature, after which it is diluted to a gallon. The current in this case can be stronger than in the previous ones. The strength is maintained by additions of platonic hydrate. The double alkaline phosphates may be used, and are prepared by neutralising the above with the alkali, and then adding an excess of phosphoric acid. The deposit is described as brilliant and adherent, with the same steely appearance as with the oxalate, but to a less pronounced degree.

The author states that Professor Dudley has, quite independently, worked out, in a precisely similar manner, the problem of electro-plating with iridium. His work is not published, but he employed, in 1886, a bath made up of,

preferably, the double sulphate of iridium and ammonium, maintaining the strength by hydroxide of iridium suspended in canvas bags near or around the anodes.—A. W.

#### *The Electrolysis of Metallic Phosphates in Acid Solution.*

E. F. Smith. Amer. Chem. J. **12**, 329-336.

See under XXIII., page 898.

##### *Improvements in Galvanic Batteries and in Electrolytic Baths.*

J. L. Roberts and H. L. Breyvoort, Brooklyn, U.S.A. Eng. Pat. 18,494, December 18, 1888. (Reprint.) 8d.

ALREADY appeared, this Journal, 1889, 623.—B. T.

##### *Improvements in Galvanic Batteries.*

A. Schanschieff, London. Eng. Pat. 7,005, April 26, 1889. 6d.

THE battery cell is made in the form of a drum (or box) by the rotation of which through a quarter of a revolution the electrodes can be either immersed in or withdrawn from the electrolyte.

One quarter of the drum is cut out by two *radial* planes at right angles; radial covers are then fitted on, to one of which the electrodes are fixed. When the electrodes are out of the liquid, they occupy one-third, and the liquid the remaining two thirds of the interior of the cell.—E. T.

##### *Improved Means for Supporting and Separating the Plates of Electric Accumulators.*

R. E. B. Crompton, London. Eng. Pat. 12,901, August 15, 1889. 6d.

A PAIR of notched double rails of suitable insulating material are used to support the plates in each cell, each double rail being made up of two single rails held apart at suitable intervals by short bars. Each rail is notched at regular intervals, and gaps are cut in the material between the notches; the single rails are then joined together by the before-mentioned bars in such a way that the notches of one are opposite the gaps of the other. All the positive plates will then rest in the notches of one rail, passing through the gaps of the attached rail and will rest in a similar manner in the notches of one of the rails opposite, while all the negative plates rest in the notches of the other two rails. A pair of supporting feet are provided for each pair of rails.—B. T.

##### *Electrolytic Treatment of Vegetable Matters and Cereals for the Production of Starch.*

E. Hermite, E. J. Paterson, and C. F. Cooper, London. Eng. Pat. 12,906, August 15, 1889. 4d.

See under XVI., page 878.

##### *Improvements in the Construction of Electric Accumulators.*

G. Downing, London. From J. F. Weyde and F. Clas, Cassioire, Hungary, and J. Eloner, Paris, France. Eng. Pat. 13,459, August 27, 1889. 1s. 3d.

THE active material is pressed into solid sticks or bars of any desired cross-section, and these bars are held firmly in plates of lead bent into a zigzag or corrugated tube form to make the electrodes. For large accumulators frames of wood, celluloid, porcelain, or other insulators may be coated with lead, and used to retain the active material. Various modes of suspension and connexion of the plates are described.—B. T.

##### *Improvements in Electric Glow Lamps.*

A. Berstein, London. Eng. Pat. 14,656, September 17, 1889. 6d.

CONDUCTING wires of springy nickel are used inside the lamp, and are so constructed as to very nearly approach one another at one part while they are held apart at one end by a glass distance-piece and at the other by the carbon rod. Should the carbon rod break, the springiness of the nickel conductors brings them into contact, so short-circuiting the lamp.—B. T.

*Improvements in or Relating to Secondary Batteries.*

P. J. R. Dujardin, Paris, France. Eng. Pat. 14,971, September 23, 1889. 6d.

In order to keep the plates of secondary cells at a uniform and unchangeable distance apart, even when the cells are moved about, the spaces between them are filled with "artificial white stone" broken into small pieces. This stone is prepared by compressing a paste of fine white sand and water, and burning in a kiln.

To regulate the potential difference in an incandescent circuit fed from accumulators, as the E.M.F. of the latter varies, a high resistance relay is placed across the mains, and according to the position of its tongue, causes one or other of two armatures to tremble like the armature of an electric bell, and so work a ratchet wheel, which causes resistance to be inserted into, or removed from, the circuit till the correct voltage is regained.—E. T.

*Improvements in Electrical Furnaces and their Manipulation.*

T. Parker, Wolverhampton. Eng. Pat. 17,060, October 29, 1889. 8d.

In this furnace the working electrodes, if of carbon, are held in metal sockets—kept cool if necessary by circulating water—at the required working distance. The arc is started by supplementary small electrodes inserted into the furnace temporarily. The electrodes may be kept in order by introducing fine or divided carbon on to their ends while the furnace is working. The potential difference between the ends of the carbons is regulated by a rheostat in the field magnet circuit of the dynamo, the carbons themselves not being moved.—E. T.

*An Improved Fluid for Primary Batteries.*

T. Coad, London. Eng. Pat. 1347, January 25, 1890. 4d.

"Nitric acid, mercury, carbonate of potash, carbonate of soda, bichromate of potash, sulphuric acid, common soda and water" are employed in varying proportions in this single fluid battery according to the nature of the work required.—B. T.

*Improvements in Electric Batteries Working with Two*

*Liquids or Electrolytes.* H. Weymerseh and R. McKenzie, London. Eng. Pat. 2302, February 12, 1890. 8d.

THE casing containing the cells of this two-fluid battery is provided with two channels, preferably in the bottom of the casing, one channel communicating with all the cells which are to contain one electrolyte, and the other channel with those which are to contain the other electrolyte; a gauge-glass and tap are provided at the outside end of each channel so that the cells can either be filled or emptied to any given level without taking the battery to pieces.

—B. T.

*An Improved Electrolytic Solution for Galvanic Batteries.*

L. Weigert, Berlin, Germany. Eng. Pat. 4949, March 29, 1890. 4d.

To prevent polarisation the inventor employs a solution of one or several chlorides such as zinc, copper, iron, &c. in combination either with a salt of mercury or with oxidising agents.—B. T.

*A New or Improved Storage Battery.*

A. J. Jarman, London. Eng. Pat. 6236, April 24, 1890. 8d.

PELLETS of an inactive partly soluble material are placed in position in a mould, and this mould is then filled with a suitable metallic alloy of lead and copper, or, aluminium and lead, or, aluminium and zinc, &c., to form the electrode, any desired form of terminal being provided for electrical connexion. Or long rods of the partly soluble material may be made in the form of screws, and a suitable alloy poured round them so as to form a solid block. Plates of

any desired thickness can then be cut off from this block, the cut being made at right angles to the length of the rods, the screw threads of which serve to retain the pellets in position. Several compounds, chiefly composed of lead salts, are described as suitable for the manufacture of the pellets and rods. The plates thus formed may be immersed in an electrolyte composed of an acidulated solution of alum, or of hyposulphite of soda with water and alcohol, or water alone, or acidulated sulphate of magnesium.—B. T.

*An Improved Method of Renewing the Carbon Filaments of Incandescence Electric Lamps.*

H. H. Lake, London. From La Société "L'Incandescence Electrique," Paris, France. Eng. Pat. 6581, April 29, 1890. 6d.

THE glass bulb of the lamp whose filament is to be repaired is opened at the top and the old filament removed, leaving only about 2 mm. of the old carbon upon the electrodes of platinum to serve as joining-pieces. A new filament is introduced and placed in such a position that its ends are in line and in contact with the carbon on the electrodes.

A suitable "hydrocarburet" is then introduced into the bulb so as to cover the joints, and a current of electricity passed through the joints decomposing the "hydrocarburet" and producing a deposit of carbon at the points of contact so as to form a strong joint.—B. T.

*An Improved Battery Element.*

J. N. Leysen, Amsterdam, Holland. Eng. Pat. 7383, May 12, 1890. 6d.

THIS is a modified form of Leclanché battery with the carbon and zinc placed in a loose sack filled with a mixture of retort carbon and manganese, sealed with resin and pitch, and the whole immersed in a solution of sal-ammoniac.

—B. T.

## XII.—FATS, OILS, AND SOAP MANUFACTURE.

*The Acidity of Vegetable Oils.*

Holde. Mitt. Konigl. Tech. Versuchs. 1890, 78—82.

See under XXIII., page 900.

### PATENTS.

*Ammoniated Soaps.*

C. R. Huxley, London. Eng. Pat. 11,817, July 25, 1889. 4d.

SOAP quite free from oleates is cut up in shavings and this is incorporated with gaseous ammonia by submitting the soap to the action of ammonia under a pressure of 15 lb. until every tissue of the soap is impregnated. The inventor claims that "its hygienic properties are such that it cleanses the pores of the skin which ordinary soap containing grease hermetically seals up."—K. M.

*A Manufacture of Linseed Mucns or Mucilage and the Preparation of Toilet and other Articles therefrom.*

A. Bosset, Paris, France. Eng. Pat. 13,535, August 27, 1889. 4d.

AQUEOUS extract of linseed is worked up in various ways into a variety of articles for toilet use. For example, the solution is mixed with rice starch and fecula, stirred well, passed through rollers and dried in the open air. It is pulverised, sifted, and scented as desired to form a toilet powder. From it are also prepared a shaving soap and a toilet liquid called "Lacto Neige."—A. J. K.

*Improvements in Apparatus for Purifying and Refining Oil.* E. Noppel, Philadelphia; B. Grosche and J. Bigler, New York, U.S.A. Eng. Pat. 5375, April 8, 1890. 8d.

In this apparatus the oil is heated by a steam coil and purified by settling and by repeatedly washing with water or other suitable liquid. For details of the apparatus the specification must be consulted.—K. M.

*Improvements in the Manufacture of Soap.* A. W. Rehnström, Malmö, Sweden. Eng. Pat. 7854, May 20, 1890. 4d.

Milk is used as a raw product for the manufacture of hard or soft soap.—K. M.

*Improved Composition of Soap.* G. Allen, London. Eng. Pat. 8077, May 23, 1890. 4d.

ONE part of paraffin wax is melted with one part ammonia and this compound is incorporated with 14 parts common soap.

This composition of soap is specially adapted for washing woollen goods and for preventing their shrinkage.—K. M.

### XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

*On the Atomicity of the Right-handed Russian Turpentine.* A. Shehukarev. J. Russ. Chem. Soc. 22, 290—296.

As it has been recently suggested to divide all terpenes into two classes, diatomic terpenes or pinenes, combining directly with  $\text{HCl}$ ,  $\text{Br}$ , &c.—and tetraatomic, isoterpenes or limonenes taking  $2 \text{HCl}$ ,  $2 \text{Br}$ , &c., the author undertook to verify the diatomicity of the Russian right-handed terpenes, having some doubts on this matter; his doubts being corroborated by Tilden (J. Chem. Soc. 1888, 882). The action of  $\text{Br}$  upon the hydrocarbon in dry chloroform being repeated, the results proved that the right-handed terpene in weak solution at first takes up only  $\text{Br}_2$ , but in strong solution, and especially when bromine added in excess gives an unstable compound  $\text{C}_{10}\text{H}_{16}\text{Br}_4$ , which partly decomposes into  $\text{C}_{10}\text{H}_{14}\text{Br}_3$  and  $\text{HBr}$ .—N. W. T.

#### PATENT.

*Improved Process for making Paper, Linen, and similar Material Impervious to Water.* A. J. Boulton, London. From D. Macdonald and W. T. Tassie, Toronto, Canada. Eng. Pat. 7024, May 6, 1890. 4d.

THE material is soaked in oil, preferably hot boiled linseed oil, passed between wringing rollers and dried, then completely covered with printer's ink, or similar material evenly distributed over its surface with or without pressure. The object of the invention is to render the materials under treatment impervious to water, and to give them at the same time a highly finished smooth surface.—K. M.

### XIV.—TANNING, LEATHER, GLUE, AND SIZE.

*Unhairing of Skins in the Manufacture of Sole Leather.* W. Borchers. Zeits. f. angew. Chem. 1890, 230—233.

A NUMBER of erroneous statements may be found in books about this branch of leather manufacture. Lietzmann, e.g. (*Die Herstellung der Leder*, 42) states that in the manufacture of sole leather the skins have to be subjected to a so-called putrid fermentation, technically termed "sweating process," whilst the unhairing of those skins which are intended for upper leather is effected by the influence of solutions of alkalis or alkaline earths, especially lime water. This is wrong, for each method may be employed for either purpose, and moreover by a combination of them very good sole leather is obtained. F. Fischer (*Handbuch d. chem. Technologie*) gives a practically correct rule, viz., that the "sweating process" is to be recommended for thick tough skins, and the treatment with lime water for thinner ones. The chief objects in sole leather manufacture are to obtain as good a quality and as great a weight as possible. But in the process of manufacture it is difficult to ascertain the precise time when both these features have been attained. This juncture lies not in the tanning process but in the preceding process of unhairing the skins. Whether the unhairing is done by the "sweating" or by the lime water process, in both cases very often the great mistake is made to continue the treatment until the hair can be removed quite easily. In this respect the methods applied as they are in America are much to be preferred. The skins subjected to the "sweating process" are not left in the warm rooms until the conditions for unhairing are completed, but they are taken out sooner and then placed for about seven hours in a weak lime water solution, where they are kept in constant motion by machinery. This treatment gives very good results. The "sweating process" is doubtless a process of putrefying which begins on the surface and proceeds to the interior of the skins. Ammonia compounds are hereby formed which increase the action of the lime upon the skins. Therefore, if first the "sweating process" and afterwards the lime water treatment are applied, but both to a limited extent only, we restrict as much as possible the harmful influence of both methods, which consists in dissolving and removing substances from the skins which are capable of forming good leather. Long application of the "sweating" as well as of the lime water process, even if used in weak solutions, have a very bad influence upon the skins, and cause great losses of substance. In Buffalo, N.Y., another treatment came into use which gives favourable results as regards weight and texture of the leather. The skins are soaked for about seven hours in a strong solution of lime water, where they are kept in motion, then put into warm water for one night, and after that they are generally ready for unhairing. Should it, however, happen that after this process the hair is not easily removed, then the skins are treated once more in warm water. When it is considered what great losses constantly occur in leather manufacture by improper treatments in the unhairing of skins, especially by the common practice of applying lime water for as long a time as three or four days, the value of a knowledge of the above-mentioned facts in this branch of sole leather manufacture will be recognised.—H. S.

#### PATENT.

*Improvements in Machinery for Dressing or otherwise Preparing Hides, Skins, and Leather.* J. Hall, Leeds. Eng. Pat. 11,138, July 10, 1889. 11d.

THE improvements relate to the construction of machines for preparing leather. The claims are:—(1.) The application and use in leather-working machines of a cam on the crank pin for reciprocating the tool head by means of a rigid connecting rod in combination with a roller or face on a rigid connecting rod for imparting the required rocking motion to the tool-holder." (2.) The application and use in

leather-working machines of the various "stops" and means for actuating same from any desired point for the purpose of facilitating the lifting of one or other of the tools off the leather while the machine is in motion and thus being able to increase the working speed. (3.) "The construction of apparatus shown in the drawings" which accompany the specification.—B. II.

## XV.—AGRICULTURE, MANURES, Etc.

*Memoranda of the Origin, Plan, and Results of the Field and other Experiments, Conducted on the Farm and in the Laboratory of Sir J. B. Lawes, at Rothamsted. June 1890.*

*Experiments on Barley. Thirty-eighth Season.*—On the continuously unmanured plot the amount of dressed grain was 11.25 bushels per acre, the average yield over the first 19 years being 20.1 bushels, and over the second 19 years 13.25 bushels. The plot manured with superphosphate (3.5 cwt. per acre) gave 20 bushels per acre, which is nearly as much as the average yield over the whole 38 years (21.75 bushels). The produce with ammonium salts alone (200 lb. per acre per annum) and with sodium nitrate alone (275 lb.) amounted to 22.5 and 25.25 bushels respectively. The highest yield (42.1 bushels per acre) was on the plot manured with sodium nitrate, sodium silicate, and superphosphate; but the farmyard manure plot (14 tons per acre) gave nearly as much (41.75 bushels); the average yield over the whole period (38 years) is for the former plot 45, and for the latter 48.4, bushels per acre. When ammonium salts and sodium nitrate are supplemented by superphosphate, the average yields (38 years) are raised from 29.25 and 32.75 to 42.9 and 45.75 bushels respectively.

*Experiments on Wheat. Forty-sixth Season.*—The unmanured plot yielded 12.25 bushels per acre, not much less than the average over the first 38 years (13 bushels). The highest average yield (36.5 bushels) is that of the plot which received potassium sulphate (200 lb.), sodium and magnesium sulphates (each 100 lb.) superphosphate

(3.5 cwt.), and ammonium salts (600 lb. per acre), whilst the next highest (35.5 bushels) is the plot receiving the same minerals but sodium nitrate (275 lb.) instead of the ammonium salts. The farmyard manure (14 tons per acre) plot, which gave the highest yield this season (40.5 bushels), gave an average of 34 bushels over the first 38 years. A complete mineral manuring (as in the ammonia and nitrate plots already mentioned), but without nitrogen, gave 15.1 bushels this year, which is practically the same as the average yield (15 bushels) over the first 38 years. On the other hand nitrate alone (275 lb.) and ammonium salts alone (400 lb.) gave the respective average annual produce 22.9 and 20.25 bushels. The plots which are alternately manured with ammonium salts (400 lb.) and minerals, gave this season: ammonia plot 23.4 bushels, mineral plot 10.25 bushels.

*Experiments on Mangel Wurzel. Fourteenth Season.*—The highest amount of produce was obtained from the plot treated with farmyard manure (14 tons) and superphosphate (3.5 cwt.), and cross-dressed with sodium nitrate (550 lb. per acre), the yield of roots being 33 tons 19 cwt. per acre. Nearly as much produce was obtained on that portion of the same plot which was cross-dressed with rape-cake (2,000 lb.) and ammonium salts (400 lb.). Of the plots which received no farmyard manure or rape-cake, the greatest weight of roots was obtained by manuring with superphosphate (3.5 cwt.), potassium sulphate (500 lb.), sodium chloride (200 lb.), and magnesium sulphate (200 lb.) with a cross-dressing of sodium nitrate (550 lb.). The yield of this plot was 22 tons 12 cwt. per acre, but there had been a loss, probably of about 1 ton per acre, owing to a heavy rainfall in July. Where no organic or nitrogenous manure is applied, the yield of roots is very much less; thus, the portion of the last-mentioned plot which received no cross-dressing, yielded only 7 tons 9 cwt., and this is the highest yield of the purely mineral plots. On the other hand, a comparatively low yield (12 tons 7 cwt. per acre) was obtained with a cross-dressing of sodium nitrate (550 lb.) on the plot which was otherwise left unmanured. The unmanured plot gave 4 tons 12 cwt. of roots per acre.

*Experiments on Potatoes. Fourteenth Season.*—The following table shows the manuring of the different plots, and the yield of tubers per acre this season and the average yields over the first and second periods of five years:—

Plots.	Manures per Acre per Annum.	Produce per Acre.				
		Average.			1889.	
		1876-80.	1881-85.			
		Tons. Cwt.	Tons. Cwt.	Tons. Cwt.		
1	Unmanured in 1876, and each year since.....	2 6½	1 19½	0 16½		
2	Unmanured in 1882, and since. Previously farmyard manure (14 tons) .....	4 13½	4 7½	1 13		
3	Farmyard manure (14 tons) alone 1883 and since; previously 3½ cwt. of superphosphate also .....	5 6½	5 1½	1 19½		
4	Farmyard manure (14 tons) alone 1883 and since. In 1882, and previously, 3½ cwt. of superphosphate, and in 1881, and previously, 550 lb. of sodium nitrate .....	6 14½	5 0½	2 18½		
5	400 lb. of ammonium salts .....	2 10½	2 7½	1 4½		
6	550 lb. of sodium nitrate.....	3 4	2 8½	1 12		
7	400 lb. of ammonium salts, 3½ cwt. of superphosphate, 300 lb. of potassium sulphate, 100 lb. of sodium sulphate, 100 lb. of magnesium sulphate .....	6 17½	7 43½	3 9		
8	550 lb. of sodium nitrate, 3½ cwt. of superphosphate, 300 lb. of potassium sulphate, 100 lb. of sodium sulphate, 100 lb. of magnesium sulphate .....	7 6½	6 17½	3 11½		
9	3½ cwt. of superphosphate .....	3 13½	4 6½	1 18½		
10	3½ cwt. of superphosphate, 300 lb. of potassium sulphate, 100 lb. of sodium sulphate, and 100 lb. of magnesium sulphate .....	3 15½	4 6	2 5½		

**SERIES I.—REPORTS OF FIELD EXPERIMENTS, EXPERIMENTS ON VEGETATION, &c.** Published 1847—1890, inclusive.

The following lists give the titles of the papers already published, arranged in two series, and within each series

arranged in chronological order; and they show where each paper appeared.

1. Agricultural Chemistry (J. Roy. Agric. Soc. Eng. 8, 226), 1847.

2. Agricultural Chemistry, Turnip Culture (J. Roy. Agric. Soc. Eng. **8**, 491), 1847.
3. Experimental Investigation into the Amount of Water Given Off by Plants during their Growth, especially in relation to the Fixation and Source of their various Constituents (J. Hort. Soc. Lond. **5**, 38), 1850.
4. Report of some Experiments undertaken at the suggestion of Professor Lindley, to ascertain the Comparative Evaporating Properties of Evergreen and Deciduous Trees (J. Hort. Soc. Lond. **6**, 227), 1851.
5. Agricultural Chemistry, especially in relation to the Mineral Theory of Baron Liebig (J. Roy. Agric. Soc. Eng. **12**, 1), 1851.
6. On the Amounts of, and Methods of Estimating, Ammonia and Nitric Acid in Rain-water (Brit. Assoc. Report, 1854).
7. Report to the Right Hon. the Earl of Leicester on the Experiments, conducted by Mr. Keary, on the Growth of Wheat upon the same Land for Four successive Years at Holkham Park Farm (J. Roy. Agric. Soc. Eng. **16**, 207), 1855.
8. On some Points connected with Agricultural Chemistry; being a Reply to Baron Liebig's "Principles of Agricultural Chemistry" (J. Roy. Agric. Soc. Eng. **16**, 411), 1855.
9. On the Growth of Wheat by the Lois Weedon System, on the Rothamsted Soil; and on the Combined Nitrogen in Soils (J. Roy. Agric. Soc. Eng. **17**, 582), 1856.
10. On some Points in the Composition of Wheat Grain, its Products in the Mill, and Bread (J. Chem. Soc. **10**, 1), 1857.
11. On the Growth of Barley by Different Manures continuously on the same Land; and on the Position of the Crop in Rotation (J. Roy. Agric. Soc. Eng. **18**, 454), 1857.
12. Report of Experiments with Different Manures on Permanent Meadow Land, with Tabular Appendix (J. Roy. Agric. Soc. Eng. **19**, 532, and **20**, 228 and 398), 1858—59.
13. Report of Experiments on the Growth of Red Clover by different Manures (J. Roy. Agric. Soc. Eng. **21**, 178), 1860.
14. On the Sources of the Nitrogen of Vegetation; with special Reference to the Question whether Plants assimilate Free or Uncombined Nitrogen. Abstract (Proc. Roy. Soc. **10**, 544), 1860.
15. On the Application of Different Manures to Different Crops, and on their proper Distribution on the Farm, 1861.
16. On some Points in connection with the Exhaustion of Soils. Abstract (Brit. Assoc. Report, 1861).
17. On the Sources of the Nitrogen of Vegetation, with special Reference to the Question whether Plants assimilate Free or Uncombined Nitrogen (Phil. Trans. Part 2, 1861).
18. Report of Experiments made at Rodmersham, Kent, on the Growth of Wheat by different Descriptions of Manure for several Years in succession on the same Land (J. Roy. Agric. Soc. Eng. **23**, 31), 1862.
19. The Effects of different Manures on the Mixed Herbage of Grass Land (J. Roy. Agric. Soc. Eng. **24**, 131), 1863.
20. On the Sources of the Nitrogen of Vegetation, with special Reference to the Question whether Plants assimilate Free or Uncombined Nitrogen (J. Chem. Soc. **16**), 1863.
21. Liebig and the "Mineral Theory" (note, extracted from a Paper by Messrs. Lawes and Gilbert, J. Roy. Agric. Soc. Eng. **24** (2)), 1863.
22. Further Report of Experiments with different Manures on Permanent Meadow Land (J. Roy. Agric. Soc. Eng. **24** (2)), 1863.
23. Report of Experiments on the Growth of Wheat for Twenty Years in succession on the same Land (J. Roy. Agric. Soc. Eng. **25** (1 and 2)), 1864.
24. On the Selection of Artificial Manures for the Sugar-cane, 1864.
25. On the Accumulation of the Nitrogen of Manure in the Soil (Brit. Assoc. Report, 1866).
26. Preliminary Notice of Results on the Composition of Wheat grown for Twenty Years in succession on the same Land (Brit. Assoc. Report, 1867).
27. On the Home Produce, Imports, and Consumption of Wheat (J. Roy. Agric. Soc. Eng. **4** [2], Part 2), 1868.
28. Exhaustion of the Soil in relation to Landlords' Covenants, and the Valuation of Unexhausted Improvements (read before the London Farmers' Club, April 4, 1870).
29. Scientific Agriculture with a View to Profit (read before the Maidstone Farmers' Club, December 15, 1870).
30. Reports of Experiments on the Influence of various Manures on different Species of Plants (Proc. Roy. Hort. Soc. 1870).
31. Effects of the Drought of 1870 on some of the Experimental Crops at Rothamsted (J. Roy. Agric. Soc. Eng. **7** [2], Part 1), 1871.
32. Notes on Clover Sickness (J. Roy. Hort. Soc. **3**), 1871.
33. Report of Experiments on the Growth of Barley for Twenty Years in succession on the same Land (J. Roy. Agric. Soc. Eng. **9** [2], Parts 1 and 2), 1873.
34. Unexhausted Tillages and Manures, with reference to the Landlord and Tenant (Ireland) Act, 1870, 1874.
35. On the more frequent Growth of Barley on Heavy Land (read before the London Farmers' Club, February 1, 1875).
36. On the Valuation of Unexhausted Manures (J. Roy. Agric. Soc. Eng. **9** [2], Part 1), 1875.
37. Note on the Occurrence of "Fairy Rings" (J. Linn. Soc. Botany, **15**, 17), 1875.
38. On some Points in connection with Vegetation (Address delivered at South Kensington in the Chemical Section of the Science Conference), 1876.
39. On Rainfall, Evaporation, and Percolation (Proc. Inst. Civil Eng. **14**, Part 3), 1876.
40. Freedom in the Growth and Sale of the Crops of the Farm, considered in relation to the Interests of the Landowner and the Tenant Farmer (J. Soc. Arts, December 14, 1877).
41. Composition of Potatoes (J. Roy. Hort. Soc. **5**, Part 5; Proceedings, p. xxxvii.), 1878.
42. On Nitrification; Reports of Experiments made in the Rothamsted Laboratory. (Part I., J. Chem. Soc., January 1878; Part II., J. Chem. Soc. July 1879; Part III., J. Chem. Soc., December 1884.) See also Brit. Assoc. Report, 1881; J. Chem. Soc. October 1885, February 1887, and August 1888. 1878—88.
43. Is Higher Farming a Remedy for Lower Prices? (Lecture delivered before the East Berwickshire Agricultural Association, May 3, 1879. Published by G. Macaskie, "Warder" Office, Berwick).
44. On the Determination of Nitric Acid as Nitric Oxide, by means of its Action on Mercury; a Report of Experiments made in the Rothamsted Laboratory (J. Chem. Soc. July 1879).
45. On the Determination of Nitric Acid by Means of Indigo, with special Reference to Water Analysis; a Report of Experiments made in the Rothamsted Laboratory (J. Chem. Soc. September 1879.) See also—Chem. News, February 2 and 9, 1877.
46. Agricultural, Botanical, and Chemical Results of Experiments on the Mixed Herbage of Permanent Meadow, conducted for more than Twenty Years in succession on the same Land. Part I., the Agricultural Results. Abstract (Proc. Roy. Soc., No. 197, 1879).
47. On some Points in connection with Agricultural Chemistry. Abstract (Brit. Assoc. Report, 1879).
48. Our Climate and our Wheat Crops (J. Roy. Agric. Soc. Eng. **16** [2], Part 1), 1880.
49. On the Home Produce, Imports, Consumption, and Price of Wheat over Twenty-eight (or Twenty-seven) Harvest Years, 1852—53 to 1879—80, inclusive (Jour. of the Statistical Society, June 1880).
50. Agricultural, Botanical, and Chemical Results of Experiments on the Mixed Herbage of Permanent Meadow, conducted for more than Twenty Years in succession on the same Land. Part I., the Agricultural Results. Full Paper (Phil. Trans. 1880 [1]).
51. Sketch of the Progress of Agricultural Chemistry; Address to the Chemical Section of the British Association (Brit. Assoc. Report, 1880).
52. On the Determination of Nitric Acid as Nitric Oxide by means of its Reaction with Ferrous Salts. Reports of

Experiments made in the Rothamsted Laboratory. (Part I., J. Chem. Soc. July 1880. Part II., J. Chem. Soc. August 1882).

53. On the Determination of Carbon in Soils; a Report of Experiments made in the Rothamsted Laboratory (J. Chem. Soc. September 1880), 1880.

54. On the Home Produce, Imports, Consumption, and Price of Wheat over Twenty-seven (or Twenty-eight) Harvest-Years, 1852—53 to 1879—80 (J. Roy. Agric. Soc. Eng. **16** [2], Part 2), 1880.

55. Agricultural, Botanical, and Chemical Results of Experiments on the Mixed Herbage of Permanent Meadow, conducted for more than Twenty Years in succession on the same Land. Part II., The Botanical Results. Abstract (Proc. Roy. Soc. **30**, 556), 1880.

56. Letter on "Bread Reform" (J. Soc. Arts, January 21, 1881).

57. On the Amount and Composition of the Rain and Drainage-Waters collected at Rothamsted; Parts I., II., and III. (J. Roy. Agric. Soc. Eng. **17** [2], 241—279 and 311—350; **18** [2], 1—71). In the separate copies of the entire paper, Section 3 of Part III. is given as Part IV., and Appended Tables are also added, 1881—82.

58. Letters on "Fertility" (Agricultural Gazette, Feb. 21 and 28; March 7, 14, and 21; April 4, 11, 18, and 25; May 2 and 9, 1881).

59. Some Practical Aspects of recent Investigations on Nitrification (J. Soc. Arts, April 7, 1882).

60. Determinations of Nitrogen in the Soils of some of the Experimental Fields at Rothamsted, and the Bearing of the Results on the Question of the Sources of the Nitrogen of our Crops. (Read at the Meeting of the American Association for the Advancement of Science at Montreal, August 1882).

61. Agricultural, Botanical, and Chemical Results of Experiments on the Mixed Herbage of Permanent Meadow, conducted for more than Twenty Years in succession on the same Land. Part II., The Botanical Results. Full Paper. (Phil. Trans. 1882 [4]).

61A. On the Determination of Nitric Acid in Soils. (J. Chem. Soc. August 1882).

61B. On some of the Changes which Nitrogenous Matter undergoes within the Soil (Lecture delivered at South Kensington, April 16, 1883).

62. Contribution to the Chemistry of "Fairy Rings" (J. Chem. Soc. May 1883).

63. New Determinations of Ammonia, Chlorine, and Sulphuric Acid in the Rain-water collected at Rothamsted (J. Roy. Agric. Soc. Eng. **19** [2], Part 2), 1883.

64. The Nitrogen as Nitric Acid in the Soils and Subsoils of some of the Fields at Rothamsted (J. Roy. Agric. Soc. Eng. **19** [2], Part 2, 1883).

65. On the Composition of the Ash of Wheat-Grain and Wheat-Straw grown at Rothamsted in different Seasons and by different Manures (J. Chem. Soc. August 1884).

66. Report of Experiments on the Growth of Wheat for the Second Period of Twenty Years in succession on the same Land (J. Roy. Agric. Soc. Eng. **20** [2], Part 2, 1884).

67. On some Points in the Composition of Soils; with Results illustrating the Sources of the Fertility of Manitoba Prairie Soils (J. Chem. Soc. 1885, 380).

68. On Agricultural Investigation; being a Lecture delivered at the Michigan State Agricultural College, Lansing, Mich., October 14, 1884, and at Rutgers College, New Brunswick, N.J., October 27, 1884.

69. Note on some Conditions of the Development, and of the Activity, of Chlorophyll. Abstract (Brit. Assoc. Report, 1885).

70. On the Valuation of Unexhausted Manures (J. Roy. Agric. Soc. Eng. **21** [2], Part 2), 1885.

71. Results of Experiments at Rothamsted on the Growth of Barley for more than Thirty Years in succession on the same Land (Agricultural Students' Gazette, New Series, **3**, Part 1), 1886.

72. Remarques sur la relation qui existe entre les sommes de température et la production agricole (Arch. des sciences phys. et nat., Troisième période, **16**, No. 11, 15 Novembre, 1886).

73. The Home Produce, Imports, Consumption and Price of Wheat in the United Kingdom, Thirty-four Harvest years, 1852—53 to 1885—86 ("The Field," February 12, 1887).

74. A contribution to the Study of Well Waters (J. Chem. Soc. June 1887), 1887.

75. On the present position of the question of the Sources of the Nitrogen of Vegetation, with some new results, and preliminary notice of new lines of investigation. Preliminary Notice (Proc. Roy. Soc. **43**, 108), 1887.

76. Results of Experiments at Rothamsted on the Growth of Root-crops for many years in succession on the same Land (Agricultural Students' Gazette, New Series, **3** [5]), 1887.

77. On the Present Position of the Question of the Sources of Nitrogen of Vegetation, with some new Results, and Preliminary Notice of New Lines of Investigation. Full Paper. (Phil. Trans. **180** (1889), B., pp. 1—107).

78. Results of Experiments at Rothamsted on the Growth of Potatoes for twelve years in succession on the same Land (Agricultural Students' Gazette, New Series, **4**, Part 2, 1888).

79. The History of a Field newly laid down to Permanent Grass (J. Roy. Agric. Soc. Eng. **25** [2], Part 1, 1889).

80. The Amount of Nitric Acid in the Rain-Water at Rothamsted, with Notes on the Analysis of Rain-Water (J. Chem. Soc. August 1889).

81. Results of Experiments at Rothamsted on the Growth of Leguminous Crops for many years in succession on the same Land (Agricultural Students' Gazette, New Series, **4**, Parts V. and VI.), 1889—90.

82. New Experiments on the question of the Fixation of Free Nitrogen. Preliminary Notice (Proc. Roy. Soc. **47**, 85), 1890.

83. The Food of our Agricultural Crops (J. Roy. Agric. Soc. Eng. **1** [3], Part 1, 1890).

#### SERIES II.—REPORTS OF EXPERIMENTS ON THE FEEDING OF ANIMALS, SEWAGE UTILISATION, ENSILAGE, &c. Published 1849—1885, inclusive.

1. Agricultural Chemistry; Sheep Feeding and Manure, Part 1. (With Tabular Appendix in 1856.) (J. Roy. Agric. Soc. Eng. **10**, 276), 1849.

2. Report of Experiments on the Comparative Fattening Qualities of Different Breeds of Sheep; Hampshire and Sussex Downs (J. Roy. Agric. Soc. Eng. **12**, 414), 1851.

3. Report of Experiments on the Comparative Fattening Qualities of Different Breeds of Sheep; Cotswolds (J. Roy. Agric. Soc. Eng. **13**, 179), 1852.

4. On the Composition of Foods in relation to Respiration and the Feeding of Animals (Brit. Assoc. Report, 1852).

5. Agricultural Chemistry: Pig Feeding (J. Roy. Agric. Soc. Eng. **14**, 459), 1853.

6. On the Equivalency of Starch and Sugar in Food (Brit. Assoc. Report, 1854).

7. Experiments on the Comparative Fattening Qualities of Different Breeds of Sheep; Leicesters and Cross-breeds (J. Roy. Agric. Soc. Eng. **16**, 45), 1855.

8. On the Sewage of London (J. Soc. Arts, March 7, 1855).

9. Letter on the Utilisation of Town Sewage (from the Report ordered by the House of Commons to be printed, August 3, 1857. Appendix xii., 477).

10. Experimental Inquiry into the Composition of some of the Animals Fed and Slaughtered as Human Food. Abstract (Proc. Roy. Soc. **9**, 348), 1858.

11. Observations on the recently-introduced Manufactured Foods for Agricultural Stock (J. Roy. Agric. Soc. Eng. **19**, 199), 1858.

12. Experimental Inquiry into the Composition of some of the Animals Fed and Slaughtered as Human Food (Phil. Trans. Part 2, 1859).

13. On the Composition of Oxen, Sheep, and Pigs, and of their Increase while Fattening (J. Roy. Agric. Soc. Eng. **21**, 433), 1860.

14. On the Composition of the Animal Portion of our Food, and on its relations to bread. Abstract (J. Chem. Soc. **12**, 54), 1860.

15. Fifth Report of Experiments on the Feeding of Sheep (J. Roy. Agric. Soc. Eng. **22**, 189), 1861.
16. Report of Experiments on the Fattening of Oxen at Woburn Park Farm (J. Roy. Agric. Soc. Eng. **22**, 200), 1861.

*Corn (Maize) Experiments.*—Maize not being a British crop, the experiments may be briefly summarised. Increased yields on this "blue grass" soil followed the use of potash fertilisers and of potash and nitrogen combined, but phosphates or nitrogen without potash showed a loss instead of a profit. Sulphate and chloride of potassium produced identical results. Potash salts (160 lb. per acre) applied the year before to plots of maize greatly increased the yield, and this year the same plots showed almost as great an increase of yield, although no fresh dressings were applied. Analyses show that whereas the crop on the unmanured plots removed 17.4 lb. of  $K_2O$  per acre from the soil, that on the potash manured plots contained 43—52 lb. per acre; the amount applied in the potash manures was 80 lb. of  $K_2O$  per acre, so that less than half is recovered the first season. The same is true of phosphoric acid. In the case of nitrogen the maximum crop took up over threefold the amount applied as manure.

*Experiments with Commercial Fertilisers on Hemp.*—The soil was a much worn "blue grass" soil shown by experiments with other crops to respond to the use of potash fertilisers; oats were taken the previous year. The various manures were broadcasted just before sowing the hemp:—

Plot.	Fertiliser.	Lb. per Acre used.	Height of Plant.	Fibre per Acre.	Increase.	Quality.
1	None .....	..	Feet. 4½	Lb. 720	..	Poor; not strong; too short.
2	Sodium nitrate .....	160	} 7½	1,120	410	Good hand spinning.
	Soil .....	480				
3	Superphosphate .....	320	} 6	860	140	Fair.
	Soil .....	320				
5	Soil .....	480	} 6½	1,050	330	Fair hemp; good strength.
	Potassium chloride .....	160				
6	Sodium nitrate .....	160	} 7	1,210	520	Too short to make good quality.
	Soil .....	120				
	Superphosphate .....	320				
7	Sodium nitrate .....	160	} 8	1,500	780	Good strength and quality.
	Soil .....	160				
	Potassium chloride .....	320				
9	Superphosphate .....	320	} 5½	900	350	Only fit for shorts.
	Potassium chloride .....	160				
	Soil .....	160				
10	Superphosphate .....	20	} 7	1,360	810	Extra hand spinning hemp.
	Potassium chloride .....	160				
	Sodium nitrate .....	160				
11	Land plaster .....	160	4	550	..	

Potash and nitrogen are therefore required on this soil, and a good fertiliser for hemp should contain 12 per cent. of potash, 4 per cent. of nitrogen, and, say, 6 per cent. of soluble phosphoric acid. All the manures used showed a margin of profit, those on plots 7 and 10 nearly doubling the value of the crop. Potassium sulphate tried against an equal weight of chloride gave almost identical results, so the latter manure, being cheaper, is preferable. Ammonium sulphate tried against an equivalent quantity of sodium nitrate gave nearly an equal result—1,320 lb. fibre against 1,380 lb. Doubling the potash salt, whether sulphate or chloride, scarcely increased the yield. Doubling the sodium nitrate and the ammonium sulphate scarcely increased the yield or quality.—J. M. H. M.

*Experiments on the Gain and Loss of Nitrogen by Cultivated and Fallow Soils.* A. Pagnoul. Compt. Rend. 110, 910—912.

THESE experiments were made from March 1888 to March 1890. Six pots of impermeable earthenware, 34 cm. in height, and containing 22 kilos. of earth with a surface of 7.54 square decimetres were so constructed that the drainage water could be collected. To the earth was added 5 grms.

The drainage water gave the following results:—

	A.	a.	B.	b.	C.	c.
Ammoniacal nitrogen.....	0.025	0.017	0.024	0.020	0.021	0.01
Nitrogen in the form of nitrate.....	0.942	0.762	0.047	0.068	0.191	0.16

In March 1890 a sample of the earth was taken from each pot with a cylindrical borer and analysed. The results are tabulated as follows:—

	A.	a.	B.	b.	C.	c.
	Grms.	Grms.	Grms.	Grms.	Grms.	Grms.
(1) Nitrogen remaining in soil.....	24.640	23.730	26.180	27.720	29.260	32.310
(2) Nitrogen assimilated by crops.....	..	..	1.490	1.456	4.266	4.144
(3) Nitrogen carried off by drainage.....	0.967	0.779	0.071	0.088	0.212	0.184
Totals.....	25.607	24.539	27.741	29.264	33.738	36.638

Subtracting the nitrogen originally present (23.980 grms.) from these totals, then—

Nitrogen absorbed from the air during two years..	1.627	0.559	3.761	5.284	9.758	12.668
---	-------	-------	-------	-------	-------	--------

Finally, if from these numbers be subtracted the amount of nitrogen assimilated by the crops and carried off by drainage (taking the means for each pair of pots) then the actual increase of nitrogen in the soil is—

	For each Pot, in Grms.	Per Hectare, in Kilos.
Fallow soil.....	0.220	29
Soil sown with grass .....	2.970	394
Soil sown with clover ....	6.820	904

To sum up, the loss of ammoniacal nitrogen through drainage, was almost *nil*; the loss of nitrogen as nitrate was very considerable for fallow land, very small for grass land, considerable for land sown with one of the *Leguminosæ* (clover).

The total gain in nitrogen was sensible for fallow land, considerable for grass land, and very considerable for the

of dried blood and 1 grm. of nitrogen as ammonium sulphate. The total amount of nitrogen in each pot was as follows:—

	Grms.
Contained in the 22 kilos. of earth .....	22.440
Contained in the dried blood .....	0.540
Contained in the ammonium sulphate .....	1.000
Total .....	23.980

The pots were lettered A, B, C, *a*, *b*, *c*: A and *a* were allowed to lie fallow, B and *b* planted with grass, C and *c* with clover.

The yields dried and analysed gave the following results:—

	1888.			1889.		
	Weight.	Nitrogen Per Cent.	Total Nitrogen.	Weight.	Nitrogen Per Cent.	Total Nitrogen.
B	41.0	3.08	1.263	10.7	2.13	0.227
<i>b</i>	42.0	3.08	1.294	7.7	2.10	0.162
C	74.5	3.92	2.990	36.3	3.71	1.346
<i>c</i>	72.5	3.92	2.843	37.5	3.47	1.301

clover land. On the fallow land the loss of nitrogen by drainage was greater in the second year than in the first, but it was less in the cultivated land. Notwithstanding this fact, and the continued gain of nitrogen by the soil, the second year's crops were smaller than the first year's. The author thinks that this singularity is due to the nature of the plants chosen, as oats sown this year are stronger on the clover land than on the grass land, and stronger on this than on the fallow land.—P. J. H.

*On the Role of Green Manures as Suppliers of Nitrogen.* A. Muntz. Compt. Rend. 110, 972—975.

GREEN plants are buried in the soil in many places as manure, and with good results. The plants generally chosen are those supposed to absorb nitrogen from the air, especially the *Leguminosæ*. Although it cannot be considered, as a rule, advantageous to sacrifice one crop for the sake of the next, yet in cases where the soil is deficient in humus, or where other manure cannot easily be obtained, this process may well be resorted to.

The action of green manures must be chiefly attributed to their nitrogen. Now, as plants generally take up their nitrogen from nitrates, the value of nitrogenous manures may be measured by their rate of nitrification.

Experiments were therefore tried with various samples of earth, differently manured, but containing each 1 gram. of nitrogen per kilo.

With a light soil containing 2 per cent. of calcium carbonate, the quantities of nitric acid per kilo. of earth produced in three months, were found to be—

	Megms. of Nitric Acid per Kilo.
1. Earth with green manure (lupin) .....	183
Earth with dried blood.....	161
Earth with ammonium sulphate.....	268

With a heavy soil containing but little calcium carbonate, the following results were obtained in the same time:—

	Megms. of Nitric Acid per Kilo.
1. Earth with green manure (lupin) .....	88.0
Earth with dried blood.....	3.6
Earth with ammonium sulphate.....	5.1

Thus, with a light soil green manure was superior to dried blood, and with a heavy soil much superior both to dried blood and ammonium sulphate.

The green manure, by its large volume, renders the heavy impermeable soils less compact, the air circulates more easily, and favours the development of the nitrification organisms. Culture experiments were carried out on the farm at Vincennes on a light soil, to which nitrogenous

manures were added, so that there were present 100 kilos. of nitrogen per hectare, other necessary elements being abundant.

A very exhausting plant, the giant maize, was sown for forage.

Eighteen days after having manured the soil, it was analysed, and the crops were cut and weighed at the end of September. The results obtained were as follows:—

	Nitric Acid in Megms. per Kilo. after 18 Days.	Weight of Yield in Kilos. per Hectare.
Portion with green manure (lucerne) .....	86.0	78,000
Portion with dried blood.....	72.2	71,500
Portion with ammonium sulphate....	121.4	66,000
Portion with no nitrogenous manure.	14.5	39,500
Portion with sodium nitrate .....	..	78,500

The author concludes that the efficacy of green manures is due to their rapid nitrification and to their favourable influence on the physical constitution of the soil.—P. J. H.

#### Copper Salts as Preventives of Potato Blight. A. Girard. Compt. Rend. 110, 1089—1092.

THE author has made a series of experiments to show the power possessed by copper salts of preventing the ravages of potato blight (*Phytophthora infestans*). The first experiments were made in August 1888, at Joinville-le-Pont and Clichy-sous-Bois, when the growth had begun to be attacked by blight, the action of the copper compound, in this instance, being solely curative. The dressing employed contained, per 100 litres, 1 kilo. of lime (weighed as CaO) and 3 kilos. of copper sulphate. Though the growth was far advanced, considerable benefit accrued to the crop from the application of this dressing, as the following results show:—

Variety of Potato.	Dressed Soil.			Undressed Soil.			Increase in the Proportion of Sound Tubers due to Dressing.
	Total Yield per Acre.	Diseased Tubers, per Acre.		Total Yield per Acre.	Diseased Tubers, per Acre.		
	Kilos.	Kilos.	Per Cent.	Kilos.	Kilos.	Per Cent.	Per Cent.
Eos .....	450.0	20.0	4.2	468	25.0	5.5	2.7
Kornblum .....	450.0	5.0	1.1	400	30.0	7.5	20.2
Aurélié .....	427.0	21.0	4.9	420	31.0	7.4	4.4
Gelbe rose .....	330.7	10.7	3.1	300	12.3	4.1	14.3
Jeuxey .....	414.5	25.0	6.0	365	48.0	13.1	22.9
Richter's .....	564.0	15.0	2.6	498	14.5	2.9	13.5
Red-skinned.....	460.0	33.0	7.0	423	51.0	12.0	17.0

The first three varieties were grown at Joinville, the others at Clichy. It follows from these results, (1), that a purely curative treatment does not ensure immunity from the disease; but that, (2), with certain varieties of the plant,

the proportion of sound tubers is increased to the extent of 20.2 and 22.9 per cent.

In 1889, at the same localities, a preventive treatment was tried, the results at Clichy-sous-Bois being as follows:—

Variety of Potato.	Dressed Soil.			Undressed Soil.			Increase in the Proportion of Sound Tubers due to Dressing.
	Total Yield per Acre.	Diseased Tubers, per Acre.		Total Yield per Acre.	Diseased Tubers, per Acre.		
	Kilos.	Kilos.	Per Cent.	Kilos.	Kilos.	Per Cent.	Per Cent.
Gelbe rose .....	328	..	..	308	8.0	2.6	9.3
Jenney .....	341	1	0.3	321	30.0	9.1	16.8
Richter's .....	439	..	..	421	1.0	0.2	4.3
Red-skinned .....	400	..	..	394	1.5	0.4	1.9

The author, in the original paper, shows that, after deducting the cost of the dressing, there was realised a pecuniary gain of 1.52 to 3 frs. per are (152 to 300 frs. per hectare) of surface treated.

By increasing the amount of copper salt to 3 per cent., the beneficial results are rendered still more certain.—E. B.

*The Decomposition of Rocks and the Formation of Arable Land.* A. Muntz. *Compt. Rend.* **110**, 1370—1372.

THE author regards it as probable that vegetation, and especially the lower classes of plant life, play a very important part in the disintegration of the bare rock. Indeed, he considers that the nitrifying organism itself plays indirectly a part. He suggests that the mosses and lichens, many of which cover the highest ground where vegetation is found to exist at all, cause, by the action of their roots, the numerous interstices, which afterwards serve for the more ready mechanical disintegration of the rock masses.

One of the most striking proofs of the fact that not only vegetable life but also the nitrifying organism may abound in rock is furnished by a mass obtained from the Oberland Alps, composed of a calcareous schist, and which was black and friable. This rock contained large quantities of the nitrifying organism.

The author has obtained earth from beneath the surface of glaciers which contained the nitrifying organism, the fact proving, he submits, that exposure to a low temperature for even long periods of time does not kill it, but merely prevents it from assuming the active state.—J. W. L.

improving the plant and selecting the best varieties, but this takes time. It is pointed out that "the beet sugar industry began 140 years ago, and for half of that time no one could make it pay." It encountered the same difficulties in selecting the best varieties; consequently there is good reason to hope that the sorghum sugar industry will ultimately be profitable.

Wiley speaks strongly as to the necessity of selecting favourable localities for the cultivation of this plant; present knowledge points to Central Southern Kansas as being the best adapted to this purpose. He says that: "Sorghum at present is so far inferior to the sugar beet and sugar cane as to require the help of the most favourable soil and climate in order to maintain its existence as a sugar-producing plant."—W. M.

*New Processes and Apparatus for Sugar Factories.* Dingl. *Polyt. J.* **276**, 567—572.

IN the estimation of sugar in beet juice, especially when the beets are unripe or diseased, the filtrate, after defecation with basic acetate of lead, often becomes turbid and dark, and cannot be polarised. Frolia has observed that the compound formed by the lead and chromogen is much more insoluble in an alkaline than in an acid or neutral solution, and that the addition of 1 to 2 drops of strong ammonia to such turbid solutions, with subsequent shaking and filtration, gives a perfectly clear filtrate, which can be easily polarised. In Belgium, where the beets are often paid for according to the sugar contained in them, analyses are consequently made in different laboratories to determine the amount of sugar, but it has been found that there is a great want of uniformity in the results obtained. The samples generally consist of quarters of the beet, and as several days often elapse between the different analyses, the samples lose weight considerably. The following formula has been proposed to make the correction for this loss of weight:—
$$PR = P'$$
 where P = the weight at the second analysis, P' = the weight at the first analysis, and R = amount of sugar found. The amount of sugar to be expected after the beets have dried may be calculated from the formula,  $R = \frac{ZP}{P}$

where Z = the original amount of sugar. These formulae would give correct results if the beet did not undergo alteration during drying, but Masson has shown that this is not the case, and it appears that the cut beets rapidly undergo chemical change. The cause of this change is not yet known, and calls for further investigation. An apparatus has been patented by Büttner and Meyer (D.R.P. 50,990, 1889), for the treatment of beet chips with milk of lime before pressing and drying them. It has been found that exhausted cane or beet chips cannot be satisfactorily pressed unless they are impregnated with a definite quantity of lime, the simple weighing of the lime and the chips does not suffice, on account of the variation in the amount of water contained in the chips. The inventors have found that if the milk of lime be in excess, the chips abstract by chemical action from milk of lime of a given concentration practically the same amount of lime in a given time. The chips are conducted mechanically into a vessel containing milk of lime of sp. gr. 1.0035, with violent agitation, and continuously removed from it. In connexion with the question, "Is there any reason to expect any serious competition from other sweetening agents (saccharine, &c.)?" the observation has been made at a large liqueur factory in Vienna that liqueurs sweetened with saccharine when exposed in uncorked bottles, &c. quickly lose their sweet taste. Stift has made experiments to test this observation by adding different quantities of saccharine to solutions of 35 volume per cent. of the purest rectified spirit in distilled water, and keeping the samples both in closed and open vessels. No difference was observed after eight days, but after 16 days the open samples were distinctly less sweet, and the saccharine finally could not be recognised by Remsen's delicate reaction. The question as to the compound into which the saccharine is split up was not investigated.—W. M.

## XVI.—SUGAR, STARCH, GUM, Etc.

*Record of Experiments in the Production of Sugar from Sorghum in 1889.* H. W. Wiley, U.S. Department of Agriculture. *Bulletin* **26**.

THIS report gives an interesting account of the work carried on at 15 different sugar works situated in Iowa, New Jersey, Virginia, Louisiana, Maryland, and Kansas, but the results have been very discouraging. In seven factories the record is total failure. A great part of this failure must be set down to the careless and incompetent manner in which most of the factories were constructed, and also to inattention to absolute conditions of success which had been previously determined by the work of the Department.

In spite of all the commercial failure attending last year's work many of those engaged in this struggling industry are convinced that success will ultimately crown their efforts, when sufficient capital backed by thoroughly capable management really takes the matter in hand. It would appear that the sorghum sugar industry has never had a fair chance from a merely mechanical point of view.

On the other hand, the plant as at present grown is extremely variable in quality, and unreliable as to the quantity of sugar it contains. Much good work has been done under the direction of the Department in the way of

*Invert Sugar in Cane Juices.* H. Schweitzer. Chem. Zeit. 14, 1031—1032 and 1061—1062.

THE author remarks that it is only very recently that any chemical control has been exercised in the Louisiana sugar factories, and now gives the result of some observations he has made during his work last winter at the Ashton plantation, St. Charles Parish, La. The factory was one of the better class of Louisiana sugar houses. The different operations were—(1) crushing of the canes, (2) clarification of the juice with sulphurous acid, (3) further clarification with lime, (4) further clarification by heating and addition of small quantity of lime, (5) concentration in open pans, (6) concentration in vacuum pans. He analysed the liquors from the different operations, and also after keeping them for known periods, and found that delay in the crushing of the cut canes or in the treatment of the liquors was the chief source of increase of invert sugar. Were a factory so arranged that the canes and liquor could be worked without loss of time, the increase of invert sugar due to the processes would be practically nil, except during the evaporation in the open pan, and to obviate this he recommends the suppression of open pan evaporators, and their replacement by vacuum apparatus. In regard to the generally accepted opinion among sugar growers that frosty weather injures the sugar juice in the cane, his observations lead him to conclude that frost by itself has an insignificant effect on the production of invert sugar, but if the frosty weather be succeeded by very warm days the juice is injured.—W. M.

#### PATENTS.

*Improvements in Evaporators or Apparatus for the Treatment of Cane Juice.* S. Pitt, Sutton. From L. W. Tracy, New York, U.S.A. Eng. Pat. 11,136, July 10, 1889. 8d.

THIS invention relates to that class of apparatus in which cane juice is successively passed through a series of evaporators, and in transit is evaporated in a vacuum to a desired density. The pans are worked in double or triple effect, the steam driven off from the first pan passing through the coils of the second pan and so on. The invention consists in the special mode of construction of the evaporators and their connexions which can be fully understood only by reference to the drawings which accompany the specification. The evaporators are oblong in shape and in horizontal section are long and narrow; the interior of each pan contains a series of horizontal tubes through which the steam circulates and over which the liquor is allowed to fall in a fine rain-like spray.—A. J. K.

*Electrolytic Treatment of Vegetable Matters and Cereals for the Production of Starch.* E. Hermite, E. J. Paterson, and C. F. Cooper, London. Eng. Pat. 12,906, August 15, 1889. 4d.

IN the manufacture of starch from potatoes, rice and other vegetable substances, the pulpy liquor resulting from the disintegration and washing of the raw material contains in addition to the starch a considerable quantity of organic impurities. To remove these the liquor is treated by electrolysis in presence of a chloride, preferably magnesium chloride.—A. J. K.

*An Improved Process of Treating Bran and other Cereal Substances for obtaining Sugar, Starch, Food for Animals, Gum and Paper.* E. Steiger, E. Schulze, and C. Auer-Schollenberger, Zurich, Switzerland. Eng. Pat. 12,920, August 15, 1889. 6d.

THIS invention is based upon the discovery that in the bran and husk obtained in the treatment of cereals there exists a carbohydrate which the authors designate "metaraban." From "metaraban" by suitable treatment with reagents can be obtained a saccharine body consisting chiefly of arabinose, a glutinous body resembling gum arabic. The invention comprises a process for obtaining either of these two substances, and at the same time rendering the fibrous

residue suitable for the manufacture of paper. It is first necessary, however, to free the bran from the protein and other alimentary substances which it contains. For this purpose the bran is boiled for about three hours with a 1 per cent. solution of ammonia or common salt. The liquor is expressed from the solid residue which is then dried and ground. The liquor is neutralised by phosphoric acid, evaporated, dried and ground, forming the fodder meal. The dried ground bran cake from which the food substances have been extracted is boiled with dilute acid, preferably sulphuric of 1 or 2 per cent. By this means the "metaraban" is converted into sugar and dissolved out, the liquor is neutralised by carbonate of lime, decolourised by bone-black, and concentrated by evaporation. The sugar then crystallises out and consists largely of arabinose. The cellular membrane remaining is toughened by boiling with weak alkaline lye, and is then suitable for the manufacture of comparatively strong paper. If a more dilute sulphuric acid, say one-tenth to one-fifth per cent. be used in above process, no sugar will be formed, but a glutinous substance which is soluble in water and resembles gum arabic. A similar glutinous substance is obtained if a weak alkaline lye be substituted for the dilute sulphuric acid. In either case the solution is expressed from the solid residue, suitably neutralised, clarified with hydrated oxide of lead and then evaporated. A solid substance is then obtained, which has the properties of gum arabic, and is very adhesive.—A. J. K.

*An Improved Process and Apparatus for the Concentration of Saccharine and other Liquids and obtaining Crystals therefrom.* R. Raeymaeckers, Tirlemont, Belgium. Eng. Pat. 13,555, August 27, 1889. 8d.

THE improved apparatus consists in a modification of the ordinary vacuum pan. The lower half of the pan is provided internally with false sides, consisting of finely perforated plates. In a series of pans the space between the false and true sides of one pan is connected with the interior of the next pan and so on.

By the improved process the pans are worked in series. Good liquor is run into No. 1; after boiling some time the syrup and fine crystals are drawn off into No. 2 pan, leaving the larger crystals behind in No. 1. These are now boiled with more of the original liquor and the syrup again drawn off, and this goes on until the syrup from No. 1 is as good as original liquor. The contents of No. 1 are now discharged, and the crystals separated by centrifugal machine. By applying similar methods to the other pans of the series a graduated series of crystals and syrups is obtained.

—A. J. K.

*Improvements in the Production of Invert Sugar.* A. Wolf and A. Kollrepp, Berlin, Germany. Eng. Pat. 16,540, October 19, 1889. 6d.

THIS invention is based on the following observations:—(1.) The rapidity with which the inversion of saccharose takes place is, for all temperatures up to 95° C. and for all degrees of concentration of the solution of cane sugar up to about 80 per cent. by weight, dependent solely on the relation of the quantity of acid employed to the quantity of water present. Thus a solution of cane sugar of 80 per cent. strength contains only about one-sixteenth of the quantity of water contained in a 20 per cent. solution for the same quantity of sugar, hence the quantity of acid required for the complete inversion of an 80 per cent. solution, other things being equal, is only one-sixteenth of that necessary for a 20 per cent. solution. (2.) For each kind of acid there is a certain very weak degree of concentration at which, on being heated for from half an hour to an hour at about 80° to 90° C., it completely inverts cane sugar in a quantity equal to about four times the quantity of the diluted acid, and without decomposing or colouring the invert sugar. Tables are given showing the time taken for inversion with various acids, temperatures, and concentrations.—A. J. K.

## XVII.—BREWING, WINES, SPIRITS, Etc.

*The Alcoholic Fermentation of Invert Sugar.* U. Gayon and E. Dabourg. *Compt. Rend.* **110**, 865—868.

The authors have determined the fermentative action of various yeasts on invert sugar by noting the optical activity

of its fermenting solutions at regular intervals. If the relation existing between the rotatory powers and the amounts of sugar fermented be represented graphically, a parabolic curve will be obtained, of which the form is constant for the same species of yeast placed under the same conditions; but varies greatly for different species. In the following table, the results obtained by the cultivation of various yeasts at 25° C. are given.

Nature of Yeast.	Original Levo-Rotation in Saccharimeter Degrees.	Maximum Levo-Rotation in Saccharimeter Degrees.	Maximum Increase in Rotation.
1. R. Yeast, non-inverting .....	100	103	3
2. M. Brewing yeast, inverting .....	100	105	5
3. P. <i>Sacch. pastorianus</i> , inverting .....	100	107	7
4. G. Top yeast, inverting .....	100	108	8
5. H. Yeast, inverting .....	100	110	10
6. A. Do. ....	100	112	12
7. B. Brewing yeast, inverting .....	100	122	22
8. Z. Yeast, inverting .....	100	125	25
9. " <i>Mycoglossure Duclaux</i> ," non-inverting .....	100	129	29
10. <i>Mucor alternans</i> , non-inverting .....	100	165	65

The curves obtained for these yeasts are all more or less flattened in the same direction, and the rotations are always levo. The form of the curves is little modified by temperature, concentration, acidity, and other circumstances. There are other yeasts, however, which, contrary to the above, ferment the levulose faster than the dextrose. Four yeasts possessing this property are known; one of the most active is a variety of *Saccharomyces eriguus*. It has inverting power, and cultivated in an invert sugar solution at 25° C., yielded the following results:—

Duration of the Experiment.	Rotation in Sacchari- meter Divisions.	Total Un- fermented reducing Sugar per Litre.	Unfermented Dextrose per Litre.	Unfermented Levulose per Litre.
Hours. 0	-190	Grms. 102.0	Grms. 51.0	Grms. 51.0
24	-154	97.1	51.0	46.1
34	- 53	79.4	46.7	32.7
48	+ 38	61.3	43.0	18.3
58	+ 61	38.1	28.9	9.2
72	+ 57	26.3	21.2	5.1
82	+ 20	10.9	8.4	2.5
96	+ 0	0.0	0.0	0.0

The action of this yeast is greatly influenced by temperature, concentration, and acidity of the sugar solution used, as the following table will show:—

Strength of Sugar Solution.	Initial Acidity.	Temperature of the Fermentation.	Maximum Dextro- rotation.
Per Cent.		Degrees.	
10	0.0	$\begin{cases} 10 \\ 25 \\ 40 \end{cases}$	$\begin{cases} 81 \\ 41 \\ 8 \end{cases}$
10	2.4	25	23
25	0.0	$\begin{cases} 10 \\ 25 \\ 40 \end{cases}$	$\begin{cases} 123 \\ 102 \\ 73 \end{cases}$
25	2.4	25	104

In concentrated solutions at low temperatures, the levulose almost entirely disappears before the dextrose is touched. The other three yeasts mentioned have the same general properties as the above, but they have no inverting action on cane sugar. One of them is a variety of *S. apiculatus*. These researches explain certain anomalies that have been encountered in the rotatory powers of fermenting liquids, and in the analysis of raw sugars and molasses.—H. T. P.

*Alcoholic Fermentation and the Transformation of Alcohol into Aldehyde induced by Means of Champignon du Muguet (Fungus of the Lily of the Valley).* G. Linossier and G. Roux. *Compt. Rend.* **110**, 868—870.

VERY contradictory assertions have been made by different observers concerning the action of *Champignon du Muguet* on sugar solutions. In order to settle the question the authors have sown various sterilised media with a pure culture of the ferment. The maximum amounts of alcohol obtained ranged from 2.7—5.5 per cent. by volume, according to the nature of the medium employed. There were produced besides, glycerol, succinic acid, butyric acid, and very considerable quantities of aldehyde and acetic acid. The ferment does not assimilate lactose. Placed in a solution of sucrose it develops, at the expense of the sugar, without fermenting or inverting it, and in a solution of invert sugar the dextrose is destroyed most rapidly. Aldehyde and acetic acid are always produced during the development of the fungus, and in fact the oxidising properties of the ferment may be easily demonstrated by sowing some in a weak solution of alcohol containing the necessary mineral substances. The alcohol rapidly disappears, being replaced by aldehyde and acetic acid. Air is absolutely necessary for the growth of the fungus. It seems probable that the organism only effects the conversion of alcohol into aldehyde, the further oxidation into acetic acid being due to the direct action of the air. This is borne out by the fact that the ferment does not develop in a weak solution of aldehyde. Although the production of alcohol during the growth of the fungus in sugar solutions seems to warrant its classification with the saccharomyces, the authors are of opinion that it far more closely resembles certain species of *muor* in its mode of action. The maximum amount of alcohol produced is less than that formed during the growth of the less energetic varieties of saccharomyces; and, moreover, this maximum is only attained after 3—5 months. The ratio of alcohol produced, to sugar destroyed, is about 0.38, whilst for yeast it is

nearer 0.50. Further, the ratio of sugar destroyed to the crop of ferment produced is about 16—19, instead of 34 for yeast placed under identical conditions. Finally, the alcohol produced during the growth of the fungus is soon converted into aldehyde; so that it is at the same time an alcoholic ferment and an oxidising agent.—H. T. P.

*The Bouquet of Fermented Liquors.* G. Jacquemin. Compt. Rend. **110**, 1140—1142.

THE author has experimented on the various fermentations produced by different kinds of yeast in tartarised barley worts and grape juices. He has found that in common with the opinion expressed by Pasteur, the flavour and quality of the wines produced are, to a great extent, dependent on the special yeast used for fermentation. The same grape juice or tartarised barley wort submitted to the treatment of different kinds of yeast have produced wines of distinct quality and bouquet. So that from barley wort under the influence of yeasts characteristic of the grapes of Beaune, Chablis, and Riquewyhr products were formed, which possessed the well-known bouquets of these growths. Further, tartarised barley wort treated with the yeast extracted from the lees of a tun of cider gave, after fermentation, a product having the exact flavour of cider.—K. M.

*The Preparation of Wine Ferments.* A. Rommier. Compt. Rend. **110**, 1341—1343.

CAREFULLY picked grapes are crushed and placed in a flask, several experiments being started at the same time, so that the one containing least bacteria and mycoderma may finally be chosen. When fermentation has thoroughly commenced, the contents of the flask are gently shaken, and drops of the liquid are sown in flasks containing sterilised and filtered grape juice. Other flasks are inoculated from these, the operation being repeated several times at intervals of 2—4 or more days. In this manner a pure cultivation of *Saccharomyces ellipsoideus* is obtained, and in order to increase its quantity it is now sown in large bulks of grape juice. The author employs flasks plugged with sterilised cotton wool and fitted with side-tubes, which are allowed to dip into water. The yeast is employed in practice by adding 1.5 per cent. of one of the later cultivations to the grape juice immediately after pressing. In order to preserve the ferment it is separated by decantation from the liquid after complete fermentation, and placed in glass bulbs which are then sealed before the blow-pipe. Two such bulbs of yeast, obtained from grapes producing a superior class of wine, were used to start the fermentation in the juice of a common variety of grape. The fermentation was complete in eight days. The wine contained 9.5 per cent. of alcohol and had a most agreeable bouquet, which the wine from these grapes did not ordinarily possess.—H. T. P.

#### PATENTS.

*Improvements relating to Apparatus for the Pasteurisation of Beer, Wine, and other Liquids.* W. Kuhn, Clermont-Ferrand, France. Eng. Pat. 15,261, October 23, 1888; amended May 31, 1890. 8d.

THE patentee now withdraws the claims relating to the second and third methods and apparatus described in the original specification (this Journal, 1889, 719).—A. L. S.

*Improvements in the Method of Malting and Drying Grain, and in Machinery or Apparatus therefor.* J. Sleeman, Taunton. Eng. Pat. 10,891, July 5, 1889. 8d.

A SPECIAL air-tight chamber is constructed of brick, iron, or other suitable material, and it is so arranged and fitted up inside as to serve the purposes of (1) a cistern in which the grain can be steeped; (2) a germinating room; (3) a kiln for drying the malt or grain. Hence grain introduced into such a chamber can be converted into finished malt without being removed from the chamber until all the necessary operations are completed. Inside the chamber is

a cylindrical or polygonal case formed of perforated metal or woven wire work which can be made to revolve on a horizontal axis. The journals on which this axis revolves can be so lowered as to submerge the grain which is contained in the case in the water which the chamber contains during the first operation. When the steeping is finished, the chamber is supplied with fresh air at a suitable temperature for germination. And finally the grain can be dried by the introduction of dry hot air or other suitable means. Drawings are given.—A. J. K.

*Improvements in the Method of Malting and Drying Grain and in Machinery or Apparatus therefor.* J. Sleeman, Taunton. Eng. Pat. 11,844, July 25, 1889. 8d.

THIS invention consists in a special arrangement of tubes for introducing air into the germinating cell described above (Eng. Pat. 10,891), and can best be understood by reference to the drawings.—A. J. K.

*Improvements in the Manufacture of Yeast.* L. Lederer, London. Eng. Pat. 12,187, July 31, 1889. 4d.

AN infusion of hops is prepared by boiling with water a quantity equal to about  $1\frac{1}{2}$  per cent. on the total grain to be mashed. About 10 per cent. of the grain (coarsely crushed barley, malt, and rye) are steeped in the hop infusion at 145° F. and allowed to saccharify. The mash is led into wooden vessels and allowed to acidify for 30—42 hours. It is then cooled to 70° F. and about 3—6 per cent. distillery yeast added. In the meantime the remainder of the grain has been mashed, and the mixture, as above prepared, after fermenting 8—10 hours, is added to the wort. The yeast as it rises is skimmed off and led on "to a double sieve, driven from a shaft with a constant supply of cold water to force the yeast through a fine gauze into a reservoir." After standing in the reservoir an hour or more the clear water is drawn off, fresh water added, and the yeast left until pressing time. After pressing the yeast is broken up, water and spirit added if it is too dry, and packed.—A. L. S.

*Improvements in Filtering Apparatus for Alcoholic Beverages.* H. Mundorf, Pöhlfigheim, Germany. Eng. Pat. 13,258, August 22, 1889. 8d.

THE ledge at the bottom of an ordinary filtering tub, which carries the cake of paper, asbestos, or other filtering material, is provided with a notch all round, but not quite close to the inner wall of the tub. A hoop of metal is wedged into this notch, the hoop being of such breadth that its upper half, the edge of which is sharp, stands free. The pressure of the liquid being filtered causes this sharp edge to cut right into the filtering mass, and thus entirely prevents the leakage of unfiltered liquid between the edge of the filtering cake and the side of the tub. Any liquid finding its way round the edge of the cake is compelled to ascend again and thus undergo filtration. To increase the pressure on the filtering cake, the tub is fitted with an air-tight lid. The filtering mass is supported from below by a fine wire gauze net. Under this is a coarser net which rests on a light wooden grating supported by woodwork. By this means a large filtering area is obtained.—H. T. P.

*A New or Improved Process for the Purification of Mineral Oils, and for Producing Alcohol.* W. P. Thompson, Liverpool. From P. Marix, Paris, France, and N. Notkin, Moscow, Russia. Eng. Pat. 13,653, August 29, 1889. 6d.

See under H1., page 852.

*Improvements in and Relating to the Treatment of Alcoholic Liquors.* J. Hutchison, Shawlands. Eng. Pat. 14,406, September 12, 1889. 4d.

ALCOHOLIC liquors are impregnated with a suitable, tasteless gas, in order to render them effervescent. In practice, still whisky, brandy, rum, gin, wine, or other alcoholic

liquid, is placed in a strong vessel, and oxygen, ozone, or other tasteless gas is forced in. The impregnated liquid is filled into strong bottles, syphons, or other suitable vessels. Liquid syrups, or glucose may be added to the spirit before bottling, in order to produce a more crystalline effervescence resembling that of champagne. Flavouring essences may also be added to the alcoholic liquid if desired.—H. T. P.

*Improvements relating to the Manufacture of Spirit from Grain and Cereals, and to the Treatment of the By-products derived therefrom for the Production of Cattle Food, Charcoal, and Manure.* A. Manbré, sen., London. Eng. Pat. 14,719, September 18, 1889. 6d.

THE grain to be employed is finely ground and cleansed from husk. The meal is mixed with two-thirds of the total quantity of water intended to be used, and 2 to 5 lb. of malt flour are added for every 100 lb. of meal taken. The mash is raised to 180° F., being stirred all the time, and is then run into a copper or gun-metal vessel, in which the remaining third of water plus 2—3 lb. of sulphuric acid for every 100 lb. of grain used, have been previously heated to 180° F. The vessel is then closed and the temperature is raised to from 300° to 320° F., at which temperature the conversion of the starch is complete. The sulphuric acid is then neutralised by phosphate of lime. The sulpho-phosphate of lime formed greatly aids the subsequent fermentation and leads to the production of spirit free from fusel oil. The neutralised liquid is filtered and fermented, and the spirit distilled off in the usual way. Three by-products are obtained:—1. The husk, derived from the grinding of the grain; 2. The precipitate filtered off from the neutralised solution; 3. The wash left after distillation. For the production of cattle-food the by-products are mixed, either together or separately, with any suitable nutrient meal or other substance, the mixture being subsequently converted into cakes by powerful pressure. For the production of charcoal, the by-products are compressed, either separately or together; the cakes are then ground and calcined in the usual way. For the preparation of manure, the compressed by-products are ground and mixed with other suitable manure products, such as nitrates, phosphates, &c.—H. T. P.

*Improvements relating to the Manufacture of Refined Malt Extract from Barley Malt, and from Barley Malt and Amylaceous Substances, and the Treatment of the Spent Grains for the Production of Cattle Food.* A. Manbré, London. Eng. Pat. 14,928, September 21, 1889. 6d.

BEST matured barley is cleansed from all dust, seeds, broken kernels and small grain, allowed to germinate in the usual way until the arospire has attained to about one half the length of the grain, and then desiccated as usual. The desiccated barley malt is ground to a fine meal, the husks are removed and the malt meal is saccharified at a temperature not exceeding 175° F., until the desired proportion of maltose and dextrine is produced. The saccharine wort is now subjected in a strong vessel to a temperature of 275°—300° F. under pressure in order to destroy any germs of disease. After filtering and draining the wort is boiled with hops and finally evaporated to form a solid extract of malt. The process may be varied by using with the barley malt flour, suitable proportions of other amylaceous substances. The husk from the barley and the spent grains are worked up with other suitable materials, such as oatmeal, barley meal, rye meal, maize meal, bran, linseed oil, &c. into cattle food.—A. J. K.

*Improvements relating to the Production and Manufacture of Methylated Spirit and the Treatment of the By-Products derived therefrom.* A. Manbré, sen., London. Eng. Pat. 15,064, September 24, 1889. 6d.

By this method methylated spirit may be directly prepared from starchy and woody substances. In carrying out the process, any grain or mixture of grains, or other starchy substances, is reduced to a fine powder and mixed with a

suitable proportion of resinous wood, either ground or in the shape of sawdust. The mixture is diluted with water, and from 5—10 lb. of sulphuric acid are added for every 100 lb. of material taken. The liquid mass is then run into a converter and heated for one hour to 300° F. The sulphuric acid is now neutralised by means of chalk or other suitable material, and the neutralised liquid is decanted from the precipitate and fermented and distilled in the usual way. The spirit obtained is ready for use as methylated spirit. Another process is to treat the starchy meal and the wood flour separately with sulphuric acid, the saccharine solutions being subsequently mixed and fermented. Or, the solutions may be separately fermented, and the two kinds of spirit obtained mixed in suitable proportions to form methylated spirit. For the production of charcoal and manure the by-products are subjected to powerful pressure, and then finely ground. The meal is calcined if charcoal be required, or mixed with other manurial substances, such as nitrates, phosphates, &c. if manure be sought for.—H. T. P.

*A New or Improved Process and Apparatus for the Distillation and Rectification of Alcohols.* W. T. Whiteman, London. From F. Haeck, Brussels, Belgium. Eng. Pat. 6587, April 29, 1889. 8d.

THE must is first filtered through a series of conical filters constructed of a cloth called by the French "Molleton" and lined with paper pulp. If the must contain more than 30 per cent. of alcohol it must be reduced to this strength by dilution before filtration.

The distilling apparatus used consists of a boiler heated by naked steam, a distillation column placed over the boiler and surrounded by a water jacket which may be kept at any desired temperature, and a refrigerator.

The filtered must is led into the boiler and its temperature raised to 22°—24° C.; the distillation column is also kept at this temperature.

The aldehyde evaporates from the liquid in the boiler and passes through the column to the refrigerator where it is condensed and runs into a receiver. Any other substances which may have been carried off from the liquid in the boiler with the aldehyde and have been condensed in the column do not flow back into the boiler but into a special receiver.

When all the aldehyde has passed over, the temperature of the boiler and column is raised to 53°—56° C. The ordinary ethers present in the must now evaporate and traversing the column without condensation, pass into the refrigerator and thence into a receiver; in the same way as before, any higher boiling bodies which may have been carried into the column with the ethers and there condensed pass into a special receiver.

As propyl, butyl, and amyl alcohols (the disagreeable end products) are but slightly soluble in 30 per cent. alcohol and are lighter than alcohol of this strength, they float on the surface of the liquid in the boiler. The vapours which, as above described, have been distilled off at temperatures of 22° and 54° C., having thus to pass through this layer of alcohols floating on the surface of the liquid in the boiler, naturally carry off part of these with them into the column where, as has been mentioned, these latter are condensed and flow from the bottom of the column into a special receiver. This receiver is so arranged that the lighter portion of the liquid flowing into it (propyl, amyl, and butyl alcohols) is mechanically separated from the heavier portion (solution of ethyl alcohol in water), the latter being led back into the still. When no more distils over at 53°—56° C., the temperature of the boiler and column is raised to 73°—76° C., at which temperature the acetic ether evaporates and passing the column is condensed in the refrigerator. In the same way as before any bodies of higher boiling point which may have passed into the column are led into the special separating receiver. When no more ether passes over, the temperature of the boiler is raised to 85° C., and that of the column is reduced to 50° C. and the distillation continued.

When no more end products are separated from the receiver above described, the distillation is stopped and the

must run into another boiler furnished with a distillation column, the same as the first boiler but larger, and a refrigerator. The column is kept at a temperature of  $78^{\circ}\text{C}$ . by the water jacket, and the must in the boiler raised to  $85^{\circ}$ – $88^{\circ}\text{C}$ . Pure ethyl alcohol passes through the column and is condensed in the refrigerator. The water, &c. condensed in the column passes back into the boiler. The alcohol from the refrigerator is at first 97 per cent.; when the strength falls to 95 per cent. the receiver is changed, the water in the jacket of the column run away and the contents of the boiler boiled; a brandy of 42–43 per cent. and of great aromatic richness is condensed by the refrigerator.

The alcohols thus obtained contain poisonous gases. These are expelled by heating the alcohol to  $32^{\circ}\text{C}$ . in vessels provided with a condenser for 2–3 hours, during which time these gases will have been estimated.

There are many little details in the apparatus and processes which are not described here and for which reference must be made to the complete specification.—A. L. S.

*Improvements in Stills of the Coffey Type.* A. Chapman, Liverpool. Eng. Pat. 8147, May 24, 1890. 8d.

In Coffey stills the water condensed in the rectifier forms a layer about one inch in depth on each of the perforated diaphragms, and the degree of rectification obtained depends on their number. In Coffey stills as ordinarily made, these diaphragms are fixtures; and consequently the strength of the spirit cannot be altered without injuring its quality.

By this invention, one or more of the diaphragms in the rectifier can be thrown out of action, so far as having a layer of liquid on the top is concerned, without interfering with the flow of the liquid, or with the action of the respective water-seals which prevent the alcohol and water vapour passing up the down pipes. Several ways of effecting this in practice are suggested; but the most convenient is to construct that portion of the down pipe which projects (about one inch) above the diaphragm, in the form of an annular valve or ring, fitting over the opening in the diaphragm and sufficiently weighted to keep in its place; this valve can be lifted clear of the opening in the diaphragm by means of a lever actuated from the outside of the column. The down pipes themselves have an out-turned flange at top by means of which they are riveted to the under-side of the diaphragm. As long as the valve rests on the diaphragm the water-level remains normal (about one inch); but as soon as the valve is raised the water escapes underneath it and passes into the down pipe, thus practically putting the diaphragm out of action and leading to the production of weaker spirit.—H. T. P.

## XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

### (A).—CHEMISTRY OF FOOD.

#### PATENTS.

*An Improved Process of Treating Bran and other Cereal Substances for obtaining Sugar, Starch, Food for Animals, Gum, and Paper.* E. Steiger, E. Schulze, and C. Auer-Schollenberger, Zurich, Switzerland. Eng. Pat. 12,920, August 15, 1889. 6d.

See under XVI., page 878.

*Improvements in the Manufacture of Bread.* J. H. Besnard, Paris, France. Eng. Pat. 651, January 14, 1890. 4d.

LEAVEN of wheat or barley flour is added to dough of half hard flour, suitably salted. After the dough has risen

somewhat it is divided into lumps, put into perforated moulds, which are then closed and baked in an oven at  $110^{\circ}$ . The rising continues and the bread is thus baked under pressure.

This process produces a bread which is more consistent, less brittle, and more preservable than bread which is baked in the usual ways.—A. G. B.

### (B).—SANITARY CHEMISTRY.

#### PATENTS.

*Improvements in the Means Employed for Purifying Sewage and other Waters, and for Deodorising and Utilising the Solids and Excreta.* B. Jagger, H. B. Jagger, and A. Turley, Leeds. Eng. Pat. 5753, April 4, 1889. 6d.

ASH-RIT, town, or manufacturers' refuse, or waste products of any kind, which contain animal or vegetable matter, is carbonised in any suitable kiln or furnace. It is then broken or ground according to the purpose to which it is applied. Mixed with sewage, &c. either with or without some defecating agent, it is used to precipitate the impurities therein, the residue deposited forming a valuable manure. It may also be used either alone or in conjunction with a precipitation process as a purifying filter, through which impure or partially purified sewage may be passed. Where the pail system is employed the substance may be employed with advantage for the deodorisation of excreta.—C. C. H.

*Improvements in the Clarification or Purification of Sewage and other Foul Waters of Analogous Nature.* C. H. Harvey, London. Eng. Pat. 6994, April 26, 1889. 6d.

AN acid solution of a ferric salt is prepared by dissolving burnt pyrites, &c. or some such cheap oxide of iron in hydrochloric acid, the specific gravity of the solution being about 1.275. Soda waste (black-ash waste) or gas lime is well oxidised by exposure to the atmosphere for three or four weeks and ground to a powder. To every million gallons of sewage 1,000 lb. of the powdered waste is added and mixed therewith, followed by the addition of 62.5 gallons of the iron salt solution. Sewage so treated is rapidly and effectually clarified.—C. C. H.

*Improvements in Apparatus for Purifying Water and other Liquids.* H. Desrumaux, Brussels, Belgium. Eng. Pat. 7006, April 26, 1889. 8d.

THE specification describes and illustrates an automatic apparatus for the purposes above mentioned, and for details the specification must be referred to.—C. C. H.

*A New Apparatus for Removing, Purifying, and Freeing Noxious Gases and Vapours from Public and Private Sewers, Tunnels, Mines, Factories, Buildings, and all Places containing Impure Gases.* G. Smith, Hammer-smith. Eng. Pat. 7924, May 13, 1889. 8d.

THE new apparatus consists of two gasometers placed side by side and connected to the sewer by means of suction pipes and valves. These are alternately raised and lowered automatically by means of an engine and intermediate mechanism, which also at the proper times opens and shuts the suction and delivery valves. The foul air is delivered into a main communicating with a furnace through which it is forced and thus completely purified before discharge into the atmosphere.—C. C. H.

*Improvements in and Connected with the Purification and Filtration of Sewage and other Foul Liquids.* C. H. Beloe and F. Candy, London. Eng. Pat. 8088, May 15, 1889. 11d.

THIS specification describes a combination of sewage precipitation tanks and filters, the effluent from the tanks being

passed through a pair of filters worked side by side. The filtering bed consists of the material called "polarite" and the arrangement of the filters is such that when the bed of one has become foul, the filtered liquid from the other of the pair is conducted to the under side of the foul filter bed, and passing upward through it removes the scum and impurities originally deposited, which are carried back again to one of the empty precipitating tanks for deposition. Several modifications of the different elements of the combination are shown.—C. C. H.

*Improvements in the Treatment of Sewage, Fecal Matter, Foul Waters, or the Like, for the Purification or Deodorising thereof, and the Obtaining of Products therefrom.* B. Nicholson and T. Palmer, London. Eng. Pat. 9777, June 13, 1889. 6d.

THE sewage is treated with a mixture of slaked lime, calcium sulphate, clay, or aluminium sulphate, to which has also been added in the proportion of one-sixth of the combined weights of the lime and calcium sulphate, such a material as powdered coke, oxide of iron, spongy iron, the ashes of wood or peat, and sulphur. The sludge is separated by decantation and incinerated in a furnace; the gases given off are condensed; the incinerated sludge mixed with a fresh quantity of reagents may be again used as a precipitant. The effluent can be rendered innocuous by the addition of the aqueous solution of the gases condensed by the use of iodide of mercury, sanitas, carbolic acid or other suitable disinfectant. The burnt residue may finally be mixed with salts of iron or chromium and by fusion rendered into a pigment of any shade or colour.—C. C. H.

*Improvements in the Treatment of Sewage for the Purification thereof and the Production of Valuable Products therefrom.* C. G. Moor, Oxford. Eng. Pat. 11,798, July 24, 1889. 8d.

SLUDGE resulting from the treatment of sewage is incinerated as hereafter described and subsequently used in conjunction with sulphate of magnesium for the defecation of a further quantity of sewage. The sludge may be partially dried by exposure to air on a bed of porous material (preferably carbonised or incinerated sludge), or by means of filter presses. When dried down to contain about 25 per cent. of moisture it is burned under a forced draught in a furnace provided with a charging door, revolving grate, and draw-off door, but otherwise resembling an ordinary cupola or closed limekiln. The ammonia given off under destructive distillation in the furnace is condensed and made into sulphate of ammonia in the usual way; this is finally mixed with the carbonised ash from the sludge and forms a valuable manure.—C. C. H.

*Improved Materials for Purifying Sewage and Polluted Waters from Works or Manufactories.* T. Jones, Sedgley, and J. Jones, Wolverhampton. Eng. Pat. 14,500, September 14, 1889. 4d.

FIRECLAY shales or marls, and lime, are mixed with the sewage or polluted water as it comes from the sewers or works. The whole is then run into settling tanks. About 3 ewt. of fireclay shale or marl and 3 ewt. of lime are used to 36,000 galls. of the liquid to be purified.—A. G. B.

*An Improvement in the Means and Proportions of Materials Used for the Deodorisation, Evaporation, and, to a certain extent, Decomposition of Human Excrement, and its Transformation into a nearly Inodorous and Valuable Fertiliser.* C. W. Doughty, Augusta, Georgia, U.S.A. Eng. Pat. 2238, February 11, 1890. 4d.

CALCAREOUS marl dried at 400° F. and finely ground is used in privy boxes for the reception of the excreta and urine. The contents of the boxes are disinfected on removal by the addition of a few pounds of a mixture containing calcareous marl 391 parts, sulphate of iron 8 parts, chloride

of lime, 1 part. The compost so obtained is dried at a temperature of 250° F. and may either be used as a manure or re-used, and so fortified further, in the privy boxes. The patentee states the calcareous marl described as prepared has the power of combining with and fixing putrescible matter and preventing decomposition.—C. C. H.

## (C)—DISINFECTANTS.

### PATENTS.

*Improvements in Bleaching, Disinfecting, Purifying and Preserving Substances, and Apparatus therefor.* G. Brownen, London, and J. Gamgee, Wimbledon. Eng. Pat. 9763, June 13, 1889. 8d.

THE articles to be bleached or disinfected are moistened and placed upon perforated or "gridiron" shelves in a closed receptacle, the shelves being so arranged that the current of gas subsequently admitted passes backwards and forwards between the shelves before leaving the apparatus. At the end of and beneath the lower shelf under a suitable cover there is a lamp in which is burned a carbon bisulphide solution of sulphur. The products of combustion, which consist of the dioxides of sulphur and carbon, pass into the interior of the apparatus and so accomplish the desired effect. In some instances it may be desirable to cool the gas before it enters the bleaching chamber; this may conveniently be effected by means of a Liebig condenser. An asbestos wick is used in the lamp.—C. C. H.

*A Method and Apparatus Employed therein for Destroying the Germs of Infectious Maladies.* A. Wassmuth, Barmen, Germany. Eng. Pat. 14,562, September 16, 1889. 8d.

THIS method consists in scattering the medicine, which is to be inhaled by the patient, in the form of fine spray throughout the room; e.g., a solution is used containing 5 per cent. of "natrium chloroborosum," which is a salt composed of 9 per cent. of chlorine, 17 per cent. of sodium, 27 per cent. of boracic acid, and 47 per cent. of water.

—A. G. B.

## XIX.—PAPER, PASTEBOARD, Etc.

*The Behaviour of Wood and Cellulose at High Temperatures and Pressures in Presence of Caustic Soda.* H. Tauss. Dingl. Polyt. J. 276, 411—428.

THE author has shown in the first part of his experiments on cellulose and wood (see Dingl. Polyt. J. 273, 276—285; this Journal, 1889, 913—914), that woody substance in considerable quantity is dissolved by distilled water. Little is yet known about the relations of wood and cellulose to caustic soda, although caustic soda has been used in the manufacture of cellulose for a considerable time past. The objects of the author's experiments were to show to what extent cellulose and wood were affected and dissolved by caustic soda at different temperatures. The experiments were partly made with solutions of a concentration as is usually employed in practice, partly with more concentrated and more diluted solutions. The time of boiling was always three hours. The heating was effected at the ordinary pressure in glass vessels; for higher pressures Muecke's digester was used, but as copper is affected by alkaline solutions, iron parts were used instead of copper ones in the digester. The solutions were allowed to stand, decanted, the subsiding part filtered, well washed, dried with the filter, and weighed. The filtrates were diluted to a known volume, generally one litre, and were tested:—

1. For substances which reduce Fehling's solution (at ordinary and at higher temperatures).

2. For substances which are precipitated by an equal volume of alcohol.

3. For substances which are precipitated by acids.

4. For substances which are extracted by ether.

5. For substances which are extracted by ether after the filtrate has been acidified.

A quantitative determination of the precipitates obtained by acids and alcohol was made when possible. Those parts of the filtrate of the woody substance reducing Fehling's solution are certain kinds of sugar or similar products, those precipitated by alcohol, wood gum (according to Koch, Thomson, Weehler, and Tollens), those precipitated by acids, ulmic and resinous acids, &c.

The ether extracts gave colourations with phloroglucinol and hydrochloric acid; vanillin was eventually obtained.

The filtrates obtained by boiling cellulose with caustic soda may also contain substances reducing Fehling's solution, and, according to Koch, a compound with the formula  $4C_6H_{10}O_5NaOH$  is also precipitated by alcohol. These filtrates were also precipitated by acids and extracted with ether. The substances used for the experiments were pure Swedish filter-paper and fine chips of soft pine wood and hard beech wood. The substances were taken in an air-dried condition and the calculations made accordingly.

*I.—Boiling of Cellulose and Wood with Caustic Soda Solution of 1.09 sp. gr. (8 per cent. NaOH) at the Ordinary Pressure.*

Ten grms. of cellulose boiled three times, each time with 500 cc. of caustic soda solution, gave:—

—	1.	2.	3.	Total.	Per Cent.
Insoluble .....	8.301	7.814	7.721	..	..
Soluble .....	1.699	0.487	0.093	2.199	21.99

After the first boiling the solution was of a yellowish colour and gave no precipitate with alcohol or acid. The ether extract of the acidified liquid gave, after evaporation of the ether, a very small yellowish residue which showed no colouration with phloroglucinol and hydrochloric acid. The solutions of the other boilings gave similar reactions.

Ten grms. of soft wood, treated as before, gave:—

—	1.	2.	3.	Total.	Per Cent.
Insoluble .....	6.6105	5.926	5.480	..	..
Soluble .....	3.3895	0.6845	0.446	4.9195	49.19

Two more boilings of the same substance gave a still greater loss, viz.:—

—	4.	5.
Insoluble .....	5.157	4.863
Soluble .....	0.323	0.294

After the first boiling the solution was brown coloured; alcohol or acid precipitated only very minute quantities. The ether extract of the acidified liquid gave, after the evaporation of the ether, a yellow residue which showed a red colouration with phloroglucinol and hydrochloric acid. The solutions of the other boilings gave similar reactions.

Two grms. of hard wood, treated as before, gave:—

—	1.	2.	3.	Total.	Per Cent.
Insoluble .....	5.829	4.810	4.532	..	..
Soluble .....	4.171	1.019	0.279	5.469	54.69

After the first boiling the solution was brown coloured; alcohol precipitate (from 50 cc.) 0.137 grm. = 27.4 per cent., and acid (from 50 cc.) 0.030 grm. = 6 per cent. of the wood. The ether extract of the acidified liquid gave, after the evaporation of the ether, a residue which showed a red colouration with phloroglucinol and hydrochloric acid. The solutions of the other boilings gave similar reactions.

*II.—Boiling of Cellulose and Wood with Caustic Soda Solution of 1.09 sp. gr. (8 per cent. NaOH) at 5 Atmospheres Pressure.*

Ten grms. of cellulose boiled three times with 500 cc. of caustic soda solution gave:—

—	1.	2.	3.	Total.	Per Cent.
Insoluble .....	5.548	4.624	4.198	..	..
Soluble .....	4.452	0.924	0.426	5.802	58.02

After the first boiling the solution was brown coloured; alcohol precipitated (from 50 cc.) 0.008 grm. = 1.6 per cent., and acid (from 50 cc.) 0.005 grm. = 1 per cent. of the cellulose. The ether extract of the acidified liquid gave, after the evaporation of the ether, no colouration with phloroglucinol and hydrochloric acid. The solutions of the other boilings gave similar reactions.

Ten grms. of soft wood, treated as before, gave:—

—	1.	2.	3.	Total.	Per Cent.
Insoluble .....	4.309	3.253	2.415	..	..
Soluble .....	5.691	1.056	0.838	7.585	75.85

After the first boiling the solution was deep brown; alcohol precipitated (from 50 cc.) 0.010 grm. = 2 per cent., and acid (from 50 cc.) 0.080 grm. = 16 per cent. of the wood. The ether extract of the acidified liquid, after the evaporation of the ether, was of a yellowish colour, and showed a red colouration with phloroglucinol and hydrochloric acid. The solutions of the other boilings behaved similarly.

Ten grms. of hard wood, treated as before, gave:—

—	1.	2.	3.	Total.	Per Cent.
Insoluble .....	3.564	3.277	3.020	..	..
Soluble .....	6.436	0.287	0.257	6.980	69.80

After the first boiling the solution was deep brown; alcohol precipitated (from 50 cc.) 0.178 grm. = 35.6 per cent., and acid (from 50 cc.) 0.076 grm. = 15.2 per cent. of the wood. The ether extract of the acidified liquid, after the evaporation of the ether, was of a yellowish colour, and gave a red colouration with phloroglucinol and hydrochloric acid. The solutions of the other boilings gave similar reactions.

*III.—Boiling of Cellulose and Wood with Caustic Soda Solution of 1.09 sp. gr. (8 per cent. NaOH) at 10 Atmospheres Pressure.*

Ten grms. of cellulose, boiled three times with 500 cc. of caustic soda solution, gave:—

—	1.	2.	3.	Total.	Per Cent.
Insoluble .....	4.971	4.320	4.102	..	..
Soluble .....	5.029	0.651	0.218	5.899	58.99

After the first boiling the solution was brown; alcohol precipitated (from 50 cc.) 0.0515 grm. = 10.30 per cent., and acid (from 50 cc.) 0.0365 grm. = 7.3 per cent. of the

cellulose. The ether extract of the acidified liquid, after the evaporation of the ether, was of a brown colour, and gave no colouration with phloroglucinol and hydrochloric acid. The solutions of the other boilings gave similar reactions.

Ten grms. of soft wood, treated as before, gave:—

—	1.	2.	3.	Total.	Per Cent.
Insoluble .....	2.5675	2.111	1.820	..	..
Soluble .....	7.4325	0.4565	0.291	8.180	81.80

After the first boiling the solution was dark brown; alcohol precipitated (from 50 cc.) 0.0087 gm. = 1.7 per cent., and acid (from 50 cc.) 0.127 gm. = 25.40 per cent. of the wood. The ether extract of the acidified liquid, after the evaporation of the ether, was of a brown colour, and gave no colouration with phloroglucinol and hydrochloric acid. The solutions of the other boilings gave similar reactions.

Ten grms. of hard wood, treated as before, gave:—

—	1.	2.	3.	Total.	Per Cent.
Insoluble .....	2.934	2.492	2.061	..	..
Soluble .....	7.066	0.532	0.341	7.939	79.39

After the first boiling the solution was dark brown; alcohol precipitated (from 50 cc.) 0.0026 gm. = 0.5 per cent., and acid (from 50 cc.) 0.092 gm. = 18.4 per cent. of the wood. The ether extract of the acidified liquid gave a brown residue, which showed no colouration with phloroglucinol and hydrochloric acid. The solutions of the other boilings gave similar reactions.

#### IV.—Boiling of Cellulose and Wood with Caustic Soda Solution of 1.162 sp. gr. (14 per cent. NaOH) at the Ordinary Pressure.

Ten grms. of cellulose, boiled with 500 cc. of caustic soda solution, gave:—

Insoluble.....	7.812
Soluble .....	2.188 = 21.88 per cent.

Solution, yellow; alcohol precipitated (from 50 cc.) 0.039 gm. = 7.8 per cent. of the cellulose, only a minute quantity was precipitated by acid. The ether extract of the acidified liquid gave a yellowish residue, which showed no colouration with phloroglucinol and hydrochloric acid.

Ten grms. of soft wood, treated as before, gave:—

Insoluble.....	6.455
Soluble .....	3.545 = 35.45 per cent.

Solution, brown; alcohol precipitated (from 50 cc.) 0.024 gm. = 4.8 per cent., and acid (from 50 cc.) 0.010 gm. = 2 per cent. of the wood. The ether extract of the acidified liquid gave a brown residue, which showed no colouration with phloroglucinol and hydrochloric acid.

Ten grms. of hard wood, treated as before, gave:—

Insoluble.....	5.357
Soluble .....	4.643 = 46.43 per cent.

Solution, brown; alcohol precipitated (from 50 cc.) 0.054 gm. = 10.8 per cent., and acid (from 50 cc.) 0.028 gm. = 5.6 per cent. of the wood. The ether extract of the acidified liquid gave a yellow residue, which showed no colouration with phloroglucinol and hydrochloric acid.

#### V.—Boiling of Cellulose and Wood with Caustic Soda Solution of 1.162 sp. gr. (14 per cent. NaOH) at 5 Atmospheres Pressure.

Ten grms. of cellulose, boiled with 500 cc. of caustic soda solution, gave:—

Insoluble.....	2.267
Soluble .....	7.733 = 77.33 per cent.

Solution, brown; alcohol precipitated (from 50 cc.) 0.135 gm. = 27 per cent., and acid (from 50 cc.) 0.059 gm. = 11.80 per cent. of the cellulose. The ether extract of the acidified liquid gave yellow-brown residue, which showed no colouration with phloroglucinol and hydrochloric acid.

Ten grms. of soft wood, treated as before, gave:—

Insoluble.....	0.287
Soluble .....	9.713 = 97.13 per cent.

Solution, dark brown; alcohol precipitated (from 50 cc.) 0.134 gm. = 26.8 per cent., and acid (from 50 cc.) 0.124 gm. = 24.8 per cent. of the wood. The ether extract of the acidified liquid gave a brown residue, which showed a red-violet colouration with phloroglucinol and hydrochloric acid.

Ten grms. of hard wood, treated as before, gave:—

Insoluble.....	0.852
Soluble.....	9.148 = 91.48 per cent.

Solution, dark brown; alcohol precipitated (from 50 cc.) 0.079 gm. = 15.8 per cent., and acid (from 50 cc.) 0.168 gm. = 33.60 per cent. of the wood. The ether extract of the acidified liquid gave a yellow residue, which showed no colouration with phloroglucinol and hydrochloric acid.

#### VI.—Boiling of Cellulose and Wood with Caustic Soda Solution of 1.013 sp. gr. (3 per cent. NaOH) at the Ordinary Pressure.

Ten grms. of cellulose, boiled with 500 cc. of caustic soda solution, gave:—

Insoluble.....	8.793
Soluble .....	1.207 = 12.07 per cent.

Solution, yellow; gave with alcohol or acid no precipitate. The ether extract of the acidified liquid gave no residue.

Ten grms. of soft wood, treated as before, gave:—

Insoluble.....	7.163
Soluble .....	2.837 = 28.37 per cent.

Solution, brown; alcohol precipitated nothing, and acid (from 50 cc.) 0.0065 gm. = 1.31 per cent. of the wood. The ether extract of the acidified liquid gave a yellow residue, which showed a red colouration with phloroglucinol and hydrochloric acid.

Ten grms. of hard wood, treated as before, gave:—

Insoluble.....	6.975
Soluble.....	3.025 = 30.25 per cent.

Solution, brown; alcohol precipitated (from 50 cc.) 0.065 gm. = 13 per cent., and acid (from 50 cc.) 0.027 gm. = 5.4 per cent. of the wood. The ether extract of the acidified liquid gave a brown residue, which showed no colouration with phloroglucinol and hydrochloric acid.

#### VII.—Boiling of Cellulose and Wood with Caustic Soda Solution of 1.043 sp. gr. (3 per cent. NaOH) at 5 Atmospheres Pressure.

Ten grms. of cellulose, boiled with 500 cc. of caustic soda solution, gave:—

Insoluble.....	8.464
Soluble .....	1.536 = 15.36 per cent.

Solution, yellowish; alcohol precipitated nothing, acid almost nothing. The ether extract of the acidified liquid gave a trace of a yellow residue, which showed no colouration with phloroglucinol and hydrochloric acid.

Ten grms. of soft wood, treated as before, gave:—

Insoluble.....	4.904
Soluble.....	5.096 = 50.96 per cent.

Solution, brown; alcohol precipitated nothing, acid (from 50 cc.) 0.0797 gm. = 15.94 per cent. of the wood. The ether extract of the acidified liquid gave a yellow-brown residue, which showed a red colouration with phloroglucinol and hydrochloric acid.

Ten grms. of hard wood, treated as before, gave:—

Insoluble.....	4.434
Soluble .....	5.566 = 55.66 per cent.

Solution, deep brown; alcohol precipitated (from 50 cc.) 0.011 gm. = 2.2 per cent., and acid (from 50 cc.) 0.047 gm. = 9.4 per cent. of the wood. The ether extract of the acidified liquid gave a yellow-brown residue, which showed a red colouration with phloroglucinol and hydrochloric acid.

*VIII.—Boiling of Cellulose and Wood with Caustic Soda Solution of 1.043 sp. gr (3 per cent. NaOH) at 10 Atmospheres Pressure.*

Ten grms. of cellulose, boiled with 500 cc. of caustic soda solution, gave:—

Insoluble.....	7.972
Soluble .....	2.028 = 20.28 per cent.

Solution, yellow; alcohol precipitated (from 50 cc.) 0.043 gm. = 8.6 per cent., and acid (from 50 cc.) 0.021 gm. = 4.2 per cent. of the cellulose. The ether extract of the acidified liquid gave a yellow residue, which showed no colouration with phloroglucinol and hydrochloric acid.

Ten grms. of soft wood, treated as before, gave:—

Insoluble.....	2.969
Soluble.....	7.031 = 70.31 per cent.

Solution, yellow-brown; alcohol precipitated a minute quantity, and acid (from 50 cc.) 0.080 gm. = 16 per cent. of the wood. The ether extract of the acidified liquid gave a yellow residue, which showed no colouration with phloroglucinol and hydrochloric acid.

Ten grms. of hard wood, treated as before, gave:—

Insoluble.....	3.441
Soluble .....	6.559 = 65.59 per cent.

Solution, brown; alcohol precipitated a minute quantity, and acid (from 50 cc.) 0.070 gm. = 14 per cent. of the wood. The ether extract of the acidified liquid gave a brown residue, which showed no colouration with phloroglucinol and hydrochloric acid.

All the solutions were treated with Fehling's solution, but none of them gave a reaction. The direct extracts with ether (without acidifying the liquid) were likewise without any result.

In all experiments higher pressure and greater concentration of the alkaline solution employed, increased the solvent power of the latter.

If it be assumed that soft wood (pine wood) contain 54 per cent. of cellulose and 46 per cent. of other matters, these 46 per cent. of other substances will be dissolved after three hours' boiling by an alkaline solution of 1.043 sp. gr. (3 per cent. NaOH) at a pressure of five to six atmospheres, by an alkaline solution of 1.090 sp. gr. (8 per cent. NaOH) at a pressure of four to five atmospheres, and by an alkaline solution of 1.162 sp. gr. (14 per cent. NaOH) at a pressure of two to three atmospheres. But, if the boiling be repeated, ordinary pressure will be sufficient if an alkaline solution of 1.090 sp. gr. (8 per cent. NaOH) be used. The same rules may be applied to hard wood (beech wood), which however contains 46 per cent. of cellulose and 54 per cent. of other matters.

But a much higher pressure is often applied for technical purposes. This is done to facilitate the mechanical loosening of the fibres, but then it cannot be avoided that in the dissolving of the other substances much cellulose is lost, and in many cases only 30 or 35 per cent. of cellulose are obtained.—H. S.

*On the Use of the Edge-Runner in Paper Mills.*

E. Muth. Dingl. Polyt. J. 276, 506—513.

In paper manufacture the edge-runner not only serves to render the working of the material easier, but it also improves the article. One of the chief objects of this

machine is to disintegrate "broke"-paper. The several stones used in the construction of the edge-runner are mostly of fine-grained granite and sandstone, the bottom stones being granite and the revolving stones sandstone. Iron plates are sometimes used instead of the bottom stones, but without any special advantage. The sandstones used must be as homogeneous as possible. The two flat sides of the sandstones are generally roughly hewn, but the author thinks it would be better to have them of a smoother surface in order to prevent any loosening of the sand particles of which the stone consists, and the mixture of them with the material. The substance used for lubricating the shaft often falls in drops, and spoils the material being worked, and therefore lubricating substances of a non-liquid nature have been recommended, but this is only a partial remedy, for as soon as the machine gets warm, such substances melt. A good remedy seems to be to use a box containing hemp saturated with tallow. Mistakes are often made in fixing the edge-runner at unsuitable and dark places in the mill. It should be placed next to the beaters and always be kept as clean as possible, as well as situated in a light spot where the state of the material can be easily ascertained, and the exact time when it has to be taken out to be transferred to the beaters. In working "broke"-paper with the edge-runner, such kinds of paper as are glazed and sized in a high degree require especially careful treatment. Formerly these kinds of paper could be disintegrated only after having been boiled, and could only be employed for an inferior quality of that, but now boiling is no longer necessary, and hence they can be used in making the same kind of paper as that of which they were waste. But to produce the higher quality, the various impurities of "broke"-paper should be removed as far as possible previous to their treatment with the edge-runner. Unsized "broke"-paper can be disintegrated without any difficulty with the edge-runner by moistening it with a little water. The best way is to bring the material dry into the machine and to regulate the water supply from a small tap connected with the machine. Medium sized paper must be moistened before being brought into the edge-runner, whereas paper glazed and sized in a high degree must be soaked for some time in water of 40° to 50° C. Entire sheets should be torn before being placed in the warm water, because they would offer too much resistance to the stones of the edge-runner.

The proper quantity of water is of great importance for the more or less complete disintegration of "broke"-papers. But according to the sizing, the fibres are different in their tenacity and the moistening of the material previous to its being brought into the edge-runner, is not sufficient for paper sized in a high degree. But this has to be effected by a careful regulation of the water supply whilst the paper is in the edge-runner. As long as the material is not moist enough, the supply of fresh material must be slow to avoid stoppage. Should, however, a stoppage occur, it is best to empty the whole machine, and to divide the compressed parts mechanically. Attempts to lift the stones without removing the material in most cases fail, and the risk is run of spoiling the material. Too much water is just as bad as too little in working with the edge-runner. The proper amount is added if little water be given forth from a small quantity of the material squeezed in the hand.

The disintegration is more effected by the continuous motion and friction of the material itself than by the direct action of the stones. To use rough surfaced stones for the machine is therefore without value, as the unevenness is soon filled by the disintegrated material. This friction of the material itself explains the importance of the proper amount of the water supply, too much or too little water preventing the desired friction. It is of advantage not to empty the edge-runner entirely when new material is put in, but to leave a thin layer at the bottom in order to prevent the direct contact of the bottom stones with the revolving stones. Experience only can show when the material is ready to be taken out from the edge-runner and removed to the beater, it not being possible to apply any rule for this. If the edge-runner be emptied the material should be placed in a wooden box, which is afterwards covered with a wet piece of felt, to prevent the material from getting dry and

spoiled by impurities. It is best to continue working the material; it is always a disadvantage to let it stand. The chief use of the edge-runner is for the disintegration of "broke"-paper, but it may also be employed for wood, straw, &c. As the disintegration of these substances is preceded by boiling, the work which the edge-runner has to do in these cases is much easier than for "broke"-paper. No other machine at present exists for this treatment of "broke"-paper than the edge-runner. (See also this Journal, 1890, 320).—H. S.

*Sulphite-Pulp Boiling.* Chem. Trade J. 1890, 7, 174—176.

AN anonymous writer in the *Papier Zeitung* of September 7th, 1890, refers to the experiments of Mr. Thilmann, Kaukauna, U.S.A., on the treatment of various kinds of wood in the bisulphite-pulp manufacture (this Journal, 1890, 540), and gives a report of laboratory experiments made in the same direction with sulphite lyes, of pure aqueous solution of sulphurous acid, and of aqueous solutions of the sulphites of calcium, barium, magnesium, sodium and potassium upon wood and other raw fibrous materials. With the exception of the "*Pinus maritima*," and the sugar- and Spanish-cane (*Saccharum officinarum* and *Calamus rotundus*), the other woods and fibrous plants were all grown on German soil. The tables given show that most of the experiments were carried out at a temperature above 100° C. In each test the wood and lye were placed in a glass tube hermetically sealed, and then heated to the required temperature in an oven. The experiments made below 100° C. were made in small glass-stoppered tubes, and heated in a water-bath. From the results obtained the author arrives at the following conclusions:—

In the boilings carried on below 100° C., all the wood samples remained hard and tough. The other fibres, those of flax, straw, &c., were only half soft. In those experiments conducted above 100° C., the woods treated with pure aqueous sulphurous acid were brown, and all tests besides *Abies excelsa*, *Populus*, and sugar cane, *Saccharum officinarum*, remained hard or were brittle. But the woods treated with metallic sulphite lyes were mostly white. With calcium sulphite lye nearly all the woods were soft, white, and sufficiently boiled. Excepting *Abies excelsa* the whitest was the *populus*, whilst *Larix decidua* (larch, a strong resinous wood) remained tough. *Pinus maritima* always remained hard, and yielded a strongly aromatic odour and a sticky or viscous lye. Oak wood is, as is well known, treated with difficulty by the bisulphite methods. With magnesium, potassium, and sodium sulphite lyes, the wood remained almost always soft, or tolerably so, whilst with weak barium sulphite lye the woods were tough and hard. With this reagent, the *populus* was easily boiled, yielding soft white fibre.

## XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

*The Relation between the Physiological Properties and the Constitution of Hydro-bases.* E. Bamberger and W. Fiehn. Ber. 22, 777—778.

Among the properties of the *ac-β*-Tetrahydronaphthylamine—

the most striking is the strong *mydriasis* produced by doses which produce absolutely no other or attendant symptoms. Stern has thoroughly studied this action ("*Ueber die Wirkung der Hydronaphthylamine auf den thierischen Organismus*," *Inaug. Dissert.* Breslau, 1888, and *Virchow's Archiv.* Bd. 115, 14.)

Indisputably the most interesting action of the *ac-β*-Tetrahydronaphthylamine is the considerable rise of temperature brought about in animals, this rise amounting to 4.5°.

Almost the whole group of the hydronaphthalene bases has been studied in the direction referred to.

The properties described as shown by the tetrahydro-*β*-naphthylamine, are shared by all the alicyclic hydro-bases of the *β*-series. These peculiar properties are apparently a condition of—

1. *The presence of additive hydrogen atoms in the substituted nucleus.*

2. *The β-position of the basic atomic group.*

Consequently the circle of the mydriatic and otherwise active substances is narrower than that to which the hydro-bases of aliphatic character belong. The latter comprises all the alicyclic bases; the former only those of the *β*-series.

The following table illustrates the fact referred to:—

Mydriatic and otherwise Active.	Non-Mydriatic or otherwise Active.
<i>ac.</i> Tetrahydro- <i>β</i> -naphthylamine.	<i>ac.</i> Tetrahydro- <i>α</i> -naphthylamine.
<i>ac.</i> Tetrahydro- <i>β</i> -naphthylamine.	<i>ar.</i> Tetrahydro-ethyl- <i>β</i> -naphthylamine.
<i>ac.</i> Tetrahydrodimethyl- <i>β</i> -naphthylamine.	<i>ar.</i> Tetrahydrodimethyl- <i>β</i> -naphthylamine.
	<i>ac.</i> Tetrahydro- <i>α'</i> - <i>α'</i> (1, 5) amidonaphthol.
	<i>ac.</i> Tetrahydro- <i>α'</i> - <i>α'</i> (1, 5) naphthylenediamine.
	<i>ar.</i> <i>α'</i> - <i>β'</i> (1, 2) tetrahydronaphthylenediamine.

Thus the "carrier" representing the physiological function is that atomic group in the *β*-position—

It is even suggested that in order to the qualitative discrimination of the members of these groups that it would be most economical as regards expenditure of substance, as well as most certain as to result, to perform an experiment upon some small animal.

*Report on New Drugs and Fine Chemicals.* Merck's Bull. 1890 [5], 33—48; 1890 [6], 49—72; and 1890 [7], 73—88.

*Orexin* (phenyldihydroquinazoline hydrochloride)—

F. Penzoldt, of Erlangen University, has reported minutely as to physiological and therapeutical experiments made with this substance (Ther. Monatsh. 1890, 59).

Orexin taken internally is but very moderately toxic, in fact a dose to be decidedly toxic in the case of a man would amount to 25 grms. at least. Half a gm. produces in the healthy human subject a quickly-formed and strong appetite; indeed, to satisfy it, as a rule, the food has to be increased to twice its usual amount. Experiments showed that on the direct application of orexin to the mucous membranes of the conjunctiva and the stomach and to the subcutaneous cellular tissue, no escharotic topical action ensued.

**Laudanine.**—This is one of the rarer natural opium bases, and has only recently been prepared on a commercial scale by Merck. The yield is so small that a quantity of mother-liquors capable of yielding a pound of *Cryptopine* yields only 5 oz. of *Laudanine*. *Laudanine* dissolves with tolerable ease in boiling alcohol, recrystallising on cooling in transparent granules. It melts at about 166° C. Pure concentrated sulphuric acid dissolves it at ordinary temperatures, giving a very faint pink tint; the same acid containing some ferric oxide yields but a slightly deeper tint. When these solutions are heated up to the point of evaporation of the acid, they assume a violet colour. The colour is, however, most intense in the ferruginous solution. *Laudanine* is a strong base forming well crystallised salts. It is soluble in soda or potash solutions, and thus resembles morphine. It differs, however, from morphine in that, whilst the morphine-soda compound can be crystallised only from a highly-concentrated and preferably alcoholic solution, the *laudanine*-soda compound may be precipitated from its aqueous solution even by an excess of the soda solution. It then appears in white resplendent needles. By indifferent solvents, such as chloroform or amyl alcohol, not a trace of the alkaloid can be removed from solutions of *laudanine* in the fixed alkalis. Hence *laudanine* possesses a phenolic character; a character made evident, moreover, by the well-known ferric chloride reaction. The experiment has been tried of methylating *laudanine* and so transforming it into an allied base, just as morphine may be changed into cocaine. Hesse pointed to the probability of the natural opium alkaloid, *laudanone* being the methyl-ether of *laudanine*. Actual experiment did not yield the result expected, for instead of the analogue of cocaine being formed from *laudanine*, a *laudanine* methyl-ether was obtained, not identical with Hesse's "*laudanone*." A close study of *laudanine* and its derivatives, chemically as well as physiologically, is commended as a subject of rich promise.

**Mercuric Benzoate**,  $(C_6H_5CO_2)_2Hg + aq.$ , is formed in small, white, inodorous and insipid crystals, but slightly soluble in cold, though more readily so in hot water and in alcohol. It is a powerful antiseptic, and is successfully employed in syphilitic and similar diseases.

**Methyl Guanidine**  $NH_2C(NH_2) \cdot NH(CH_3)$ , a colourless and very deliquescent substance of alkaline reaction, soluble in water but insoluble in alcohol. Methyl guanidine kills rabbits quickly, with symptoms of dyspnoea and convulsions.

**Mururé Oil** is obtained from the Brazilian plant *Bichetea officinalis* (*Urticaceæ*) and termed "*Mururé*." In Brazil this oil is extensively used in grave cases of syphilis, the ulcerations, it is said, being very rapidly healed by it. Moreover in rheumatic pains exceedingly favourable results were obtained with *Mururé* oil. The oil is also highly spoken of as an efficacious *emmenagogue*.

**Phenyl Prethane** (Phenyl carbaminic acid)—

occurs in white crystals, insoluble in water, easily soluble in dilute and also in strong alcohol. Melting point = 49° C. Giacomini (Deutsch. med. Zeit. 1889, 71) recommends it as a reliable antipyretic, which also exercises a favourable influence on the general tone of the system. In both acute and chronic *Arthritic rheumatism* it is useful, but then somewhat larger doses are required; the analgetic effect is, however, not fully reliable.

**Sodium Silico-fluoride** ("*Salufer*"),  $Na_2F_6 : SiF_6$ , first introduced by W. Thomson, is highly spoken of by Roberts (Deutsch. med. Zeit. 1889) who states that solutions as weak as 2:1000 are efficacious for surgical antiseptic purposes. It is also commended by various authorities as a styptic and astringent in dentistry.

**Tarine.**—This is the alkaloid of the leaves of *Tarus baccata* (yew). It appears in whitish laminae, with difficulty soluble in water, readily soluble in alcohol, ether, and carbon bisulphide. Its melting point is about 110° C.

This alkaloid has been so far only investigated physiologically. It is a powerful poison, the lethal effect being asphyxia with spasms.

"**Thermine**" is the tetrahydro- $\beta$ -naphthylamine of Bamberger and preceding abstract (Ber. 22, 777). It is a colourless, limpid, slightly viscous liquid, of peculiar odour. It has very strong basic power, even fixing carbonic acid firmly, so that a drop exposed to the air soon becomes a crystalline solid, in consequence of its transformation into the carbonate of the base.

As shown by Filelme, the physiological effects of *Thermine* embrace the two very strongly marked characteristics of *Mydriasis* and *elevation of animal temperature*. The latter effect has been observed to the extent of 4½° C. The name of *Thermine* was given on account of this peculiar action.

**Thermine Hydrochloride** (Tetrahydro- $\beta$ -naphthylamine hydrochloride),  $C_{10}H_{11}NH_2 \cdot HCl$ , forms white, well-defined crystals, readily soluble in water, alcohol and amyl alcohol. Melting point = 237° C. W. de Jong has demonstrated that the *Thermine* salts cannot replace cocaine in ophthalmology since their mydriatic action, whilst not much exceeding that of cocaine in intensity, is accompanied by marked pain.

**Thioresorcinol** forms a yellowish-grey, insipid powder, insoluble in water, and but sparingly soluble in alcohol and ether.

Thioresorcinol has been proposed as a succedaneum for iodoform, but it appears from more recent trials that it is not entirely innocuous, and requires caution in its application.

**Rubidium and Caesium Compounds.**—S. Botkin (Inaugural Dissert. St. Petersburg, 1888) has investigated the physiological action of the caesium and rubidium halogen salts, both on canine and human subjects. His experiments show that the chlorides of these metals injected into the circulatory system, augment the blood pressure (chiefly by vascular contraction), whilst they also retard the heart-movement to some extent. The effect, as regards heart-action, is but of subordinate character with the rubidium salts, and it is more insignificant still with the caesium compounds. Generally, the salts of both these metals appear to be closely related to those of the alkalis as to the character of their physiologic action.

In this regard, too, rubidium bromide has lately been the subject of study. Laufenauer (Therapeutische Monatsh. 1889, 348) first pointed out the remarkable relation of the atomic weight and electro-positivity of metals to the anti-epileptic power of their bromides, this power being generally greater in proportion as the afore-named properties are higher. Accordingly, the bromides of rubidium and of caesium ought to exert stronger anti-epileptic action than the bromides of potassium or of sodium. This conclusion has been verified by Laufenauer and Karlowsky (*Pesther med. chir. Presse*, 1889, No. 27). But rubidium bromide, with which these investigators experimented, being difficult of preparation, Laufenauer recommends the following for medicinal purposes:—

**Double Rubidium and Ammonium Bromide**,  $RbBr + 3 NH_4Br$ .—A white or slightly yellowish crystalline powder, readily soluble in water. Laufenauer and Karlowsky found that in nearly all the clinical varieties of epilepsy and allied ailments, its therapeutic action corresponds in the main with that of potassium bromide. In fully one-third the number of cases treated, however, the rubidium-ammonium bromide produced an indisputably greater sedative effect than any of

the allied bromine preparations. It was also useful as a hypnotic in other cases. Leufenauer is now investigating the therapeutic action of caesium bromide.

**Caesium-Rubidium-Ammonium Bromide (the Triple Salt).**—This is the latest anti-epileptic.

**Caesium and Ammonium Bromide (Double Salt),  $CsBr + 3NH_4Br$ .**—A white crystalline powder, readily soluble in water.

**Caesium Carbonate,  $Cs_2CO_3$ .**—A sand-like white substance, melting at a red heat, very hygroscopic, very soluble in water and also soluble in alcohol.

**Caesium Hydroxide,  $CsOH$ .**—A greyish white mass, melting below a red heat, rather deliquescent, and behaving towards water or alcohol as potassium hydroxide does.

**Caesium Sulphate,  $Cs_2SO_4$ .**—Anhydrous, colourless prisms, permanent in the atmosphere; far more readily soluble in water than the corresponding potassium salt; insoluble in alcohol.

**Cocaine Hydrochloride.**—The great importance of the freedom from amorphous coca bases is borne ample testimony to by the researches of Liebermann and Liebreich. Liebermann (Ber. 21, 2344; also this Journal, 1889, 305, 566—567) discovered among the amorphous accessory bases of coca leaves a very toxic substance, Isatropyl-cocaine. G. Falkson (Inaug. Dissert. 1889, Berlin) describes in detail the physiological action of this deadly alkaloid. The yield of pure crystallised cocaine from the crude commercial cocaines is much smaller than is generally thought. Moreover the complete separation from the amorphous bases is complicated, difficult, and involves considerable loss of material.

**Amylene Hydrate (pure Medicinal) versus Sulphonal.**—A comparison has been experimentally made between these two hypnotics with the result that the hypnotic effect of amylene hydrate is secured promptly after the lapse of half an hour, and lasts for 7—9 hours, the patient finding himself rested and refreshed on awaking in the morning. This gives a preference over sulphonal, the effect of which usually supervenes only after several hours, and frequently continues all through the following day in a disagreeable manner.

**Apo-atropine** is a colourless crystalline substance, but little soluble in water, readily soluble in alcohol, chloroform, and in benzene. Melting point,  $60^{\circ}$ — $62^{\circ}$  C. It is identical with the atropyl-tropine of Pesci and of Ladenburg.

**Benzanilide,  $C_6H_5NH(CO.C_6H_5)$**  (this Journal, 1889, 476).—The results of further experiments in proof of its usefulness as an antipyretic are given. It is a white, crystalline powder, almost insoluble in water, soluble in 58 parts of cold and seven parts of hot alcohol, and but little soluble in ether.

**Butyl-chloral Hydrate,  $C_4H_9Cl_3O + aq$**  (this Journal, 1889, 476), is found in white crystalline laminae of a peculiar odour, with difficulty soluble in cold, more easily in hot water; very readily soluble in alcohol. Melting point  $= 78^{\circ}$  C. Sp. gr. = 1.69.

**Caffeine Phthalate** has been exceedingly well adopted for hypodermic use on account of its ready and perfect solubility in a small quantity of water (1:5), the alkaloid itself only possessing one-fifteenth of that solubility.

**Chloral-Ammonium,  $CCl_3CH(NH_2).OH$**  (this Journal, 1889, 413), is a white crystalline powder of taste and odour resembling chloral hydrate, but little soluble in cold water, more readily so in alcohol. Melting point  $= 64^{\circ}$  C.

**Cubic Acid,  $C_{25}H_{30}O_7$**  (Schulze), is found in officinal cubebs associated with cubebene, an ethereal oil, and with cubebin, an indifferent solid. The acid is a white, wax-like substance, soon turning brown in the air. It is readily soluble in alcohol and ether. Its therapeutic value is variously estimated. According to Bernatzik (Husemann and Hilger's "Pflanzenstoffe," 492) the acid represents the anti-blennorrhagic principle of cubebs.

**Kephir and Koumiss.**—The kephir fungus or "seeds," which the nomadic tribes of Russia use in preparing the original kephir, have now been brought into commerce, and are obtainable through the drug trade. According to Kern they consist of two fungi of totally different character, the regular brewer's yeast (*saccharomyces cerevisiae*, Meyen) and a new bacillus which, from its tendency to emit spores at both ends, he terms *Dispora caucasica*. Associated with these there appear to be some other cells, principally of *Oidium lactis*, and it has not yet been ascertained whether these are essential or accidental. The prime origin of this composite ferment has not yet been ascertained. It is certain, however, that neither common yeast nor atmospheric spores can replace with equal effect, milk fermented by either never yielding a product endowed with the dietetic and therapeutic virtues of true kephir. The appearance of good and dry kephir fungi is that of light brown or yellowish, irregular aggregations of hard roundish or oval granules from about the size of a rye-grain to that of a pea, or even larger. The odour is similar to that of fermented pure cream, or of good fresh Swiss cheese. A whitish incrustation sometimes visible in the recesses of the grains of fungi is harmless, but if greenish, mould and therefore some deterioration, is indicated.

The preparation of true kephir is next described in detail, and then the dietetic virtues and action are chemically and physiologically discussed.

**Phenylacetic Acid,  $C_6H_5.CH_2CO_2H$  (Alpha-toluic Acid) and  $\beta$ -phenylpropionic Acid,  $C_6H_5.CH_2.CH_2.CO_2H$  (Hydrocinnamic, Homotoluic, or Benzylacetic Acid).**—Both these acids have been made the subjects of comparative bacteriological research by Klein and Lingard, and both are capable, in half per cent. solutions, of destroying completely the infectious capacity of tubercular virus. Williams (Brompton Hospital) found that both phenylacetic and  $\beta$ -phenylpropionic acid given internally benefit the appetite and digestion of phthisical patients, and were well borne even in large doses.

Allivia (*Gazetta degli Ospitali*, 1888, No. 86) administered it in large doses in cases of typhus with favourable results.

**Indian Geranium Oil.** F. W. Semmler. Ber. 23, 1098—1103.

THE author has investigated several ethereal oils, more particularly geraniol, possessing the empirical formula  $C_{10}H_{18}O$ , with the object of throwing some light on the constitution of the terpenes obtainable from them, and on the manner in which certain terpenes are formed in plants. Two Indian geranium oils were examined. They were olive green in colour and possessed an agreeable pear-like odour. Their specific gravities at  $16^{\circ}$  C. were 0.8868 and 0.8871 respectively. Chemically the oils were identical, and both exerted a slight levo-rotatory action on polarised light. Distilled under a pressure of 17 mm., 92 per cent. of the oil passed over between the temperatures of  $120.5^{\circ}$ — $122.5^{\circ}$  C. The whole of this fraction was found to consist of geraniol. Geraniol is a colourless liquid of the specific gravity 0.89 at  $15^{\circ}$  C. and possesses a pleasant odour. Hitherto geraniol has been looked upon as a benzene derivative isomeric with borneol. But its high boiling point and low specific gravity as compared with borneol and similar bodies, point to the possibility of geraniol really being an open chain compound. To settle the point, the refractive index was determined and found to be at  $20^{\circ}$  C. :—

	$n_D$ .	$n_D$ .
Li .....	1.4741	
Na .....	1.4766	

Therefore  $n_D = 1.4745$ .

The molecular refraction obtained by means of the formula  $\frac{(n_D^2 - 1)P}{(n_D^2 + 1)d}$  will therefore be 48.71. Using Brühl's constants, it appears that geraniol contains at least two ethylene groups, the calculated molecular refraction being 48.66. This is confirmed by the fact that geraniol readily takes up 4 atoms of bromine or iodine. A body of the formula  $C_{10}H_{18}O$

containing two ethylene residues, cannot possibly be a benzene derivative; and as geraniol is undoubtedly an alcohol, it must belong to the series of unsaturated alcohols,  $C_{17}H_{28}O$ . On oxidation with potassium permanganate, a molecule of geraniol yields almost quantitatively a molecule of iso-valerianic acid. By the action of phosphorus pentoxide on geraniol, a terpene and a poly-terpene, boiling respectively at 60–65° C. and 205°–215° C. under a pressure of 17 mm., are obtained, the latter being splendidly dihydroic. These bodies have not yet been thoroughly examined, but they are undoubtedly benzene derivatives. Under these circumstances, two formulæ are possible for geraniol.

1. Optically active—

2. Optically inactive—

The ease with which the ether,  $(C_{10}H_{17})_2O$ , and the sulphide,  $(C_{10}H_{17})_2S$ , are formed, inclines to the latter formula. The author is continuing his researches.—H. T. P.

#### The Relation of Cocaine to Atropine. A. Einhorn.

Ber. 23, 1338–1344.

БЕЧКА has ascribed to tropine, without sufficient evidence the following constitutional formula, in which, however, he expressly states, it is uncertain whether the hydrogen atoms are attached to the  $\alpha$ ,  $\beta$ , or  $\gamma$  carbon-atoms—

If this formula be correct, tropine must bear a close relationship to ecgonine—the basic decomposition product of cocaine. This relationship is more clearly exhibited in the formulae of their respective derivatives—tropidine and anhydro-ecgonine—

Tropidine.

Anhydro-ecgonine.

the latter being the carboxylic acid of the former. The correctness of this view has been proved by experiment. The author has previously shown (this Journal, 1889, 634) that when anhydro-ecgonine is heated for eight hours at 280° C. with strong hydrochloric acid, a number of hydrogenised pyridine bases are produced. To one of these, yielding a gold salt melting at 212° C., the formula  $C_7H_{13}N$  was attributed. It now appears that the analytical results then obtained for the gold salt were incorrect, owing to the presence of a slight impurity. The base is, however, easily obtained in a state of purity by conversion into the difficultly soluble picrate. Its correct formula is  $C_8H_{13}N$ , which is the

same as that of tropidine. The complete identity of the two bodies was proved by comparing their picrates, and gold and platinum salts. A complete description of the crystalline form of these compounds follows.—H. T. P.

#### On the Preparation and Properties of Carbon Tetrafluoride. H. Moissan. Compt. Rend. 120, 951–954.

VARIOUS methods of preparing this gas are described. It is best obtained by passing the vapour of carbon tetrachloride over silver fluoride heated in a metallic tube to a temperature between 195° and 220°. The gas obtained by operating in glass has approximately the same density, but is a mixture of silicon tetrafluoride, carbonic acid, carbon tetrafluoride, and a carbon fluoride of higher density. Silicon tetrafluoride has a density of 3.09 compared to air, the theoretical number being 3.03. It is liquefiable under a pressure of four atmospheres in Cailliet's apparatus at +20° C., and under the ordinary pressure at –15° C. It is but slightly soluble in water, very soluble in ordinary ether, and especially in anhydrous alcohol. It is insoluble in monohydrated sulphuric acid, aqueous potash, and baryta solutions. In contact with a heated glass surface, the following reaction takes place gradually:—

When carbon tetrafluoride is heated with sodium, sodium fluoride is formed, and the carbon is deposited. It is absorbed by alcoholic potash and gradually converted into potassium fluoride and potassium carbonate.—P. J. H.

#### On Amethylcamphophenolsulphone and its Tetra-nitro Derivative: a Yellow Colouring Matter. P. Cazeneuve. Compt. Rend. 110, 961–964.

See under IV., page 853.

## XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

#### Manganous Sulphate in Photo-Lithography. W. Weissenberger. Phot. Corr. 27, 159–161.

PAPER coated with gelatin is sensitised on the following solution:—Water, 1,000 parts; potassium dichromate, 40 parts; manganous sulphate, 5 parts. Paper thus prepared is more sensitive than paper prepared with dichromate alone, and the quantity of dichromate reduced in a given time by light of a given intensity is considerably greater. At the same time the degree of alteration is proportional to the intensity of the light. The employment of manganous sulphate renders it unnecessary to use the concentrated solutions of dichromate which have lately been recommended.—C. H. B.

#### Recovery of Silver from Residues by means of Hydroxylamine. A. Lamer. Phot. Corr. 27, 209–212.

OLD fixing baths and other waste liquids, concentrated if possible by exposure to air and sunlight in shallow dishes, are made strongly alkaline with crude caustic alkali, heated and mixed with successive small quantities of a solution of commercial hydroxylamine chloride ("reducing salt" of the Badische Anilin und Soda-fabrik), previously made alkaline. Precipitation of the silver takes place rapidly, and after a time a small quantity of the liquid is withdrawn and filtered. One part of the filtrate is mixed with caustic alkali and heated in order to see whether excess of alkali is present, and the other part is mixed with more hydroxylamine and heated, and if further reduction takes place, more hydroxyl-

amine is added to the bulk of the liquid, and the process is continued. An excess of caustic alkali is essential to complete reduction. The precipitated silver is washed with hot water.—C. H. B.

*Ammonium Iodide.* W. Weissenberger. *Phot. Corr.* **27**, 273—274.

AMMONIUM iodide, which is largely used in the wet collodion process, is a very unstable compound, and the author has devised a method of preparing it as required from substances which themselves are quite stable. 10 grms. of potassium iodide are dissolved in 20 cc. of water, and mixed with 4 grms. of ammonium sulphate dissolved in 30 cc. of water. Absolute alcohol is now added until the volume of the liquid is 218 cc.; potassium sulphate is precipitated and the liquid contains 4 per cent. of ammonium iodide.—C. H. B.

*Iodine in the Ferrous Oxalate and Pyrogallol Developers.* A. Lainer. *Phot. Corr.* **27**, 306—307.

SMALL quantities of an alcoholic solution of iodine added to the ferrous oxalate developer reduce the contrasts in the resulting negative without affecting the amount of detail. Iodine solution added to a mixed pyrogallol developer has little effect unless added in much larger quantity than in the case of the ferrous oxalate; it then produces a very similar result. A very dilute solution of potassium iodide has a similar effect.

If iodine solution is added to the soda solution before the latter is mixed with the pyrogallol solution, very strong restraining action is observed, and if the quantity of iodine is considerable, the development of an image may be prevented altogether. This result is doubtless due to the formation of sodium iodide. The action of iodides is quite different from that of bromides, since they change the silver bromide in the film more or less completely into iodide. —C. H. B.

*Orthochromatic Photography.* L. Vida. *Phot. Corr.* **27**, 351—352.

A MIXTURE of indophenol blue and malachite green sensitises gelatin plates for yellow, orange, and red, but somewhat reduces the sensitiveness to blue, and hence may be used in place of the costly and unstable azaline (a mixture of cyanine and quinoline red). 0.1 gm. indophenol blue (naphthalene blue) is dissolved in 500 cc. of alcohol. 1 gm. of malachite green is dissolved in 200 cc. of water, heated to about 70°, and mixed with a hot solution of 10 grms. of potassium dichromate in 100 cc. of water, heated for half an hour and filtered. The precipitate is washed, dissolved in a small quantity of hot alcohol, and diluted to 250 cc. with alcohol containing 6—8 grms. of quinine sulphate.

Gelatin plates are immersed for 2 minutes in a mixture of 4 cc. of the indophenol blue solution, 4 cc. of the prepared malachite green solution, and 600 cc. of water. They are then allowed to drain, and are dried in the dark.—C. H. B.

*A Standard Method of Development.* C. H. Bothamley. *J. Photo. Soc.* **14**, 134—142.

In ordinary photographic practice the method of development must be adapted to the nature of the subject which is being dealt with, and the character of the result which is desired, but in astronomical photography, the testing of plates, and for other scientific purposes, a standard method of development is desirable. A standard method must fulfil the following conditions—(1), it must develop the maximum amount of detail which the plate is capable of giving, without producing fog, *i.e.*, without reducing metallic silver in those parts of the film which have not been acted on by light; (2), it must be simple in execution; (3), it must resemble as closely as possible the methods used in ordinary practice; (4), it must involve the use of only such chemicals as can be purchased in a state of purity, and are not hygroscopic or liable to undergo other alteration when

stored with ordinary care; (5), the solutions must be easily prepared and not liable to alteration.

The only developing agent in general use which satisfies these conditions is pyrogallol used with ammonia as an accelerator and ammonium bromide as a restrainer, or with sodium carbonate as accelerator and potassium bromide as restrainer. The use of sulphites is not admissible because their composition is very variable and their precise influence is not yet understood.

A stock solution of ammonia is made by diluting strong ammonia solution with 15 times its bulk of water, is carefully titrated with a solution of oxalic acid containing 37.06 grms. per litre (1 cc. = 0.01 gm.  $\text{NH}_3$ ) using aurin as an indicator, and is used for making up the final ammonia solution. Pure sodium carbonate is made by carefully heating the pure bicarbonate at 150°.

The author made a large number of experiments with plates of different kinds with a view to determine the influence of variations in the composition of the developer, time of development, continual or intermittent agitation of the liquid, and exposure to or exclusion of air. He found that the maximum amount of detail which can be developed on a plate which has received a given exposure is independent of variations in the composition of the developer provided that the time of action is sufficiently prolonged. The time required varies considerably in different cases and the densities of the deposits corresponding to different intensities of light are not constant. Similar results have previously been obtained by Mr. Lionel Clark. Two standard methods are recommended.

*Standard Pyro-Ammonia.*—Five parts of pyrogallol, 5 parts of ammonium bromide, 2.5 parts of real ammonia ( $\text{NH}_3$ ) in 1,000 parts by measure of the solution. Develop for 10 minutes in an open or closed vessel at 15° C. or 60° F. with occasional shaking. The developer is made up in two solutions. A. Ammonia ( $\text{NH}_3$ ) 5 parts, ammonium bromide 10 parts, water up to 1,000 parts. B. Pyrogallol 10 parts, water up to 1,000 parts. These are mixed in equal volumes immediately before use; solution A. will keep indefinitely in properly closed vessels, solution B. must be made as required.

*Standard Pyro-Soda.*—Five parts of pyrogallol, 10 parts of anhydrous sodium carbonate, 2.5 parts of potassium bromide in 1,000 parts by measure of the solution. Develop for half an hour in a closed vessel at 15° C. or 60° F. In this case also two solutions are prepared and are mixed in equal volumes immediately before use. A. Sodium carbonate 20 parts, potassium bromide 5 parts, water up to 1,000 parts. B. Pyrogallol 10 parts, water up to 1,000 parts.

The proposed standards agree very closely in composition with developers used in ordinary practice. They will develop the maximum possible amount of detail on all the different makes of plates of best repute without giving chemical fog, and any plates which will give chemical fog with these developers during the time specified may be regarded as below the highest standard of quality.—C. H. B.

*Backing for Plates.* W. E. Debenham. *J. Photo. Soc.* **14**, 203—206.

CAREFUL measurement of the relative efficiency of various substances used for backing plates in order to prevent halation, shows that bitumen, which has frequently been recommended, is very far from satisfactory. This is true also of mixtures of bitumen and lamp-black, and the result seems to be due to imperfect optical contact with the glass after the backing has dried. Carbon tissue moistened with glycerol and squeezed in contact with the glass is also unsatisfactory.

Gum and burnt sienna; gum or gelatin and burnt sugar, with or without the addition of lamp-black or Chinese ink and also gum and lamp-black make very efficient backing. The mixtures containing burnt sienna or burnt sugar show very little halation even with prolonged exposures, and the sugar confers considerable elasticity on the backing. The addition of lamp-black or Chinese ink is not necessary if a sufficiently thick coating of the mixture is laid on the plate.—C. H. B.

*Gelatinobromide Emulsions.*

BURTON (Amer. Am. Phot. 1890, 107) describes the following method of preparing an emulsion with a fine grain: 10 grms. of finely powdered dry silver nitrate are added to a solution of 7 grms. ammonium bromide, 0.5 gm. of potassium iodide and 2 grms. of soft gelatin in 124 cc. of water, previously heated to 50° C., and the mixture is violently shaken for some time. 8 grms. of hard gelatin previously swelled in water are then added, thoroughly melted, and the emulsion allowed to solidify, after which it is washed in the usual manner.

Bell (Phot. News, 34, 259) describes a novel method of preparing a highly sensitive emulsion: 60 parts of silver nitrate dissolved in 220 parts of water is mixed with a solution of 5 parts of ammonium iodide in 440 parts of water until the precipitated silver iodide ceases to dissolve. 20 parts of ammonium chloride dissolved in 220 parts of water slightly acidified with nitric acid are then added, and the silver chloride is washed three times by decantation, mixed with broken glass, and 16 parts of Nelson's No. 2 gelatin are added and melted at 32–38° F. The mixture is then thoroughly shaken and a solution of 43 parts of potassium bromide and 27 parts of strong ammonia solution in 220 parts of water is then added all at once and the vessel is corked and heated at 32° for 15 or 20 minutes. From time to time a drop of the emulsion is examined by transmitted light, and as soon as it is greyish-blue or green in colour, 120 parts of Heinrich's gelatin, previously softened in water and melted at a temperature higher than 32°, is added and the mixture is well shaken and allowed to cool slowly. After standing 6 hours it is remelted at 100° and again allowed to cool. After a second 6 hours it is remelted and is then mixed with some boiled acid emulsion, or if it is to be used alone, is allowed to set in a dish and is treated in the usual way.—C. H. B.

*Acid Fixing Bath.* F. Beach. Amer. Am. Phot. 1890, 185. 120 parts of crystallised sodium sulphite is dissolved in 1,000 parts of water, 90 parts of powdered chrome alum and 15 parts (by vol.) of sulphuric acid are added, and the liquid is mixed with a solution of 1,000 parts of sodium thiosulphate in 3,000 parts of water. This bath has the advantage that it exerts a very powerful astringent action on the film and thus prevents frilling.—C. H. B.

*Combined Toning and Fixing Bath.* Liesegang. Phot. Arch. 1890, 118.

1,000 parts of sodium thiosulphate, 400 parts of alum, and 10 parts of lead nitrate are dissolved in 2,000 parts of water. After 2 days, 2,000 parts of water are added, the liquid filtered, mixed with a solution of 800 parts of ammonium thiocyanate in 6,000 parts of water, and 50 to 100 parts of a 1 per cent. gold chloride solution are added. Acidification with tartaric acid accelerates the toning but impairs the whites of the prints. Sodium acetate, phosphate, and benzoate, reduce the action of the toning bath, but give somewhat warmer tones.

If potassium chloroplatinite is used instead of gold chloride a platinum toning and fixing bath is obtained.

—C. H. B.

*Ferric Chloride for Copper Etching.* W. Weissenberger, Phot. Wochenblatt, 16, 210.

Ferric chloride containing only 2 per cent. of free hydrochloric acid attacks even a coarse grain somewhat energetically. For fine work neutral ferric chloride is therefore indispensable and it can be prepared in the following manner. 1,000 parts of ferric chloride are dissolved in 300 parts of water. 5 parts of this solution are diluted with 500 parts of water and precipitated with potassium hydroxide. The well-washed precipitate is added to the original solution, and after one or two days the cleared liquid is decanted from the undissolved precipitate.—C. H. B.

## PATENTS.

*Improvements in or relating to Films or Supports for Photographic Negatives or Prints.* J. S. Fairfax, London. From F. Crane, New Jersey, U.S.A. Eng. Pat. 10,393, June 26, 1889. 6d.

A METHOD of preparing films or supports of pyroxylin which can afterwards be coated with gelatinobromide emulsion in any suitable manner. The film may be made from a comparatively limpid solution which is flowed over a smooth surface or carrier, the desired thickness being given to the film by successive coats of the solution, which can readily be done provided that the solutions are practically saturated. It may also be made from a heavy viscous solution which is spread over the carrier by means of a knife or straight-edge, the thickness of the film being regulated by the spreader. The latter method is the quicker and cheaper of the two.

A good formula for the thin solution is: 40 galls. of methyl alcohol (wood spirit); 20 galls. of amyl, propyl, or butyl acetate, or mixtures thereof; 40 galls. of amyl alcohol; 50 lb. of soluble pyroxylin. For a viscous solution the following may be used: 55 galls. of methyl alcohol (wood spirit); 20 galls. of amyl alcohol (fusel oil); 25 galls. of amyl acetate; 50 lb. of gum camphor; and 100 lb. of soluble pyroxylin. The proportions of the constituents may be varied, butyl alcohol or its isomers may be used in place of amyl alcohol, and butyl acetate or other ethereal salts of butyl or amyl which will dissolve pyroxylin may be used in place of amyl acetate.

When the film is dry it is stripped from the carrier or temporary support and cut into pieces or into long strips for use on rollers.—C. H. B.

*Improvements in Apparatus for Coating Photographic Dry Plates and other Plane Surfaces with an Emulsion or Viscous Liquid.* J. H. Smith, Zurich, Switzerland. Eng. Pat. 11,553, July 19, 1889. 11d.

THE claims made are for a trough divided by means of a removable partition into two compartments communicating at the bottom, one serving to receive a regular stream of emulsion, whilst the other is provided with an overflow lip consisting of a flat horizontal surface or of two flat surfaces meeting at an obtuse angle; a moveable curved piece for adjusting the surface down which the liquid flows, in order to correct for the different thicknesses of the surface to be coated; rollers supported in a trough containing water, and covered with some good absorbing material so that they apply cold water to the backs of the coated plates or surfaces; rollers driven by a double worm so that increased speed can be given to the plates or other surfaces after they have been coated.—C. H. B.

*Improvements in the Treatment of Paper or other Fabrics to render them Suitable for Photographic Purposes.* J. Williams, Willesden. Eng. Pat. 12,309, August 2, 1889. 4d.

A STRONG solution of pure cuprammonium hydroxide is prepared, 1.5 to 2.5 per cent. by weight of metallic copper being used according to the brilliancy of surface required. Paper or any other fabric which is to be treated is floated on this solution, care being taken that only one surface comes in contact with the liquid. The surface is thus converted into a structureless film of cellulose, which at this stage exists in combination with the cupric oxide, ammonia, and water. The paper or other fabric, with the minimum exposure to air required to make the film set, is dried over one or more hot rollers. In order to remove the copper from the film, it is passed through successive baths of weak acid, which dissolves the copper without affecting the glazed surface.

In this way a permanent glaze resembling that of albuminised paper is obtained on paper or other fabric, and it withstands the action of water, steam, weak acids, alkalis, and ordinary solvents.

Other suitable solvents may be used in place of cuprammonium hydroxide.—C. H. B.

## XXII.—EXPLOSIVES, MATCHES, Etc.

## PATENTS.

*Improvements in the Construction of Electric Fuses and Detonators, and in the Method of and Appliances employed for Manufacturing the same.* P. Ward and E. M. Gregory, London, Eng. Pat. 11,501, July 18, 1889. 8d.

THIS patent relates to a tool by which a small plug of insulating material may be placed round the ends of the limbs of the "armature" of Eng. Pat. 3981 of 1884, so as to hold them apart at a fixed and uniform distance. The ends of the limbs project through this plug a fixed distance, and the end of the plug itself is furnished with a small cavity into which the priming material may be placed so as to surround the exposed ends of the limbs. The insulating plug with its priming is then protected by dipping into paraffin or other wax, and then into Roman or other hard cement, and may finally, if desired, be covered with a coating of fusible alloy or lead.

For detonators, after the protective coating of wax, the detonating composition is placed on the end of the fuse, and then covered with final protective coatings.—E. T.

*Process and Apparatus for the Manufacture of Explosives in the Form of Wires or Rods and for forming the same into Cartridges.* F. A. Abel, London; J. Dewar, Cambridge; and W. Anderson, London. Eng. Pat. 11,667, July 22, 1889. 11d.

THIS "invention relates to a process and apparatus for the manufacture of explosives in the form of wires or rods which are produced by mixing together certain ingredients so as to form a plastic explosive compound such as blasting gelatin or similar compounds, and then converting the compound into a wire or rod-like condition. The ingredients of the explosive are in the first place thoroughly mixed, for which purpose an ordinary kneading machine such as that used for dough may be employed; and the mixture is by means of pugging apparatus forced out by helical blades through a die into the form of a column which can be cut into suitable lengths as in a brick-making machine, these lengths being afterwards operated on by a machine, converting the material into flexible wires or rods which are wound on suitable reels."

"From the reels a number of the wires or rods are unwound and dried by passing them through a steam-jacketed tube or otherwise, and are then by means of a suitable machine formed into bundles and introduced into cartridge cases, to constitute their explosive charges."—W. M.

*Improvements Relating to the Waterproofing of Blocks, Charges, or Cartridges of Explosive Material and to Apparatus therefor.* C. Lamm, Stockholm, Sweden. Eng. Pat. 12,442, August 6, 1889. 8d.

THIS specification describes a machine for dipping blocks charges or cartridges of explosive material into a bath filled with a suitable waterproofing material kept in a liquid state. The cartridges, &c. pass down a channel on to an endless belt provided with hooks which take the cartridges and convey them to corresponding spring clamps fixed to the surface of a wheel which catch the cartridges. The lower part of the wheel is immersed in the waterproofing bath, and as the wheel rotates the cartridges are dipped into the bath and then delivered on to another endless belt which conveys them away. There are special contrivances for ensuring a uniform coating being given to the cartridges. Detailed descriptions and drawings are given of the machine.

—W. M.

*Improvements in the Manufacture of certain Fireworks for Display Purposes.* H. Stephenson, London, Eng. Pat. 14,804, September 19, 1889. 8d.

THESE improvements relate to fireworks which display a bright silver or gold star when burnt. Hitherto fireworks of this character could only be kept for two or three weeks as the iron borings employed in their manufacture were affected by the atmospheric influences and thus chemical action was set up between them and the other chemicals. The main feature of this invention is the preparatory treatment of the iron borings whereby they receive a coating of zinc and thus, after mixing with the other chemicals, the composition can be safely stored for lengthened periods without undergoing any alteration or deterioration.—W. M.

*Improvements in Making and Applying Explosives.* C. O. Lundholm and J. Sayers, Stevenston. Eng. Pat. 13,486, August 27, 1889. 6d.

THE inventors make a "sub-sensitive" explosive by gelatinising one or more nitro-derivatives of cellulose, oxy-cellulose, or hydro-cellulose, with nitro derivatives of the aromatic group of substances. The cellulose derivative is suspended in water and the aromatic nitro-compound (also diffused through water sufficiently warm to keep it liquid) is poured in with suitable agitation, or a solid nitro derivative such as dinitro-benzene may be liquefied by heat and simply poured into the liquid containing the suspended nitro-cellulose.

Explosive compounds made in this way may be used alone for filling shells or in conjunction with more sensitive explosives, such as blasting gelatin; in the latter case the less sensitive explosive is arranged outermost in the shell and the blasting gelatin in the centre.—W. M.

*An Improved Priming and Detonating Composition.* P. Ward and E. M. Gregory, London, Eng. Pat. 8481, May 31, 1890. 4d.

THIS composition consists of 2 lb. of carbon in the form of coke, 1 lb. of amorphous phosphorus, and "75 lb. of potassium chlorate." In the claim the amount is stated to be 0.75 lb. The phosphorus and chlorate are ground separately under benzene, carbon chloride or amyl acetate, and then, together with coke, still under the liquid.

Paraffin oil is added, and after the grinding fluid has evaporated this causes the composition to cake and also prevents oxidation and reduces its sensitiveness to friction or percussion without detracting from its explosive violence.

—W. M.

## XXIII.—ANALYTICAL CHEMISTRY.

## APPARATUS, &amp;c.

*On the Preparation of Gas Reduction Tubes ready for Use.* G. Lunge. Zeits. f. angew. Chem. 1890, 227—229.

THE author shows how the reduction tube mentioned in his article on the "gas volumeter" (this Journal, 1890, 547—549)—which may also be used for ordinary reduction apparatus—can be manufactured and kept ready-made for sale, so as to save the buyer the trouble of adjusting it himself by making barometer and thermometer observations at the beginning of his work. This will be desirable when using the "gas volumeter" for many technical purposes, e.g., the determination of carbon dioxide in cement manufacture, of nitrogen in ammonium sulphate, of chlorine by bleachers and dyers, in urine tests made by physicians, and for various other practical purposes. It would not be sufficiently safe, if the apparatus had to be sent to a distance, to seal up the tube at one end and to close it at the other with a stop-cock after the proper adjustment

(compare this Journal, 1890, 547—548) has been made. Absolute safety is only possible if the tube be sealed up on both ends.

For this purpose glass tubes must be used as shown in Fig. 1. *a* is a comparatively thick tube of capillary

THE PREPARATION OF REDUCTION TUBES.

bore which can, however, be sealed up with perfect ease. The part at *c* is a similar capillary tube with thick walls about 5 cm. long and terminating in the bulbs *b* and *d*, as shown in the figure. Fig. 2 shows the parts *b*, *c*, and *d* in natural size. The tube *A* is connected (as shown in Fig. 1) with the levelling tube *B*, and mercury is introduced into the latter. If the gases are to be measured moist, a small drop of water is brought into tube *A*, but if they are to be measured dry, a small drop of concentrated sulphuric acid is introduced instead of water.

By barometric and thermometric observations (the thermometer used has to be suspended closely to tube *A*) and by the use of the formula  $\frac{273(B-f)}{(273+t)760}$  for moist gases,

and  $\frac{273B}{(273+t)760}$  for dry gases, or by the use of tables

calculated therefrom, we find the volume which 100 cc. of perfectly dry air, measured at 0° C. and 760 mm., would occupy under the existing conditions. This may be, e.g., 112.3 cc. Now *B* is moved so as to have the level of the mercury in *A* at 112.3 cc., then the part *a* is covered with a piece of asbestos cloth, to prevent *A* from getting hot, and finally the capillary end of *a* is sealed up. The work can be proceeded with, if after some minutes the level of the mercury has undergone no change, but if a change has taken place, *a* has to be opened again, and the operation repeated more carefully. After that the india-rubber tube is closed tightly with a small vice (an ordinary burette clip not being sufficient), the mercury below *e* is poured off, the tube cut through at *f*, and lastly the capillary tube *c* is closed by sealing it up. This can easily be effected by holding *A* almost horizontally. The apparatus is now ready, and the author recommends that the parts *a* and *c* be covered with small india-rubber tubes for protection.

Arrived at its destination and ready for use, the "gas volumeter" is first put together, but without the reduction tube just described, as is shown in Fig. 3. The india-rubber tube *g* which is to be connected with the reduction tube is fixed vertically, and then mercury is poured into the levelling tube *B* (Fig. 3), until *g* is entirely filled. After that the reduction tube is notched with a file at its lower part at *h* (Fig. 2), this end put into the mercury of *g*, *g* being very

carefully placed over the bulb *b*, to avoid air bubbles, and lastly *c* is broken at *h* whilst inside the tube *g*. The point *h* has to be taken at a comparatively wide part of *c*, in order to enable a quick motion of the mercury when the apparatus is in use.

Another shape of the tube *A* is shown in Fig. 4, which is very convenient for large as well as for small volumes of gases. Of course the ungraduated part (between 50 and 100 cc.) has to be avoided, but this can easily be done in most cases.—H. S.

#### Apparatus for the Determination of Melting Points.

A. C. Christomanos, Ber. 23, 1093—1096.

*A* is a cylindrical glass vessel 12 × 6 cm., which is heated on a sand-bath or in an air-bath. A cork is inserted in one of the necks and carries a thermometer *C* and a stout platinum wire *f*, while the other neck is conical and ribbed to allow the tube *B* to rest firmly within it. The vessel *A* is

THE DETERMINATION OF MELTING POINTS.

filled with mercury to such a height that the lower end of the tube *B* dips into it about 2 cm. The substance the melting point of which is to be determined is fused in a test tube and a portion sucked up into *B* and allowed to solidify in its contracted part, forming a layer 0.5—1.5 cm. in thickness. The tube *B* being now restored to position, a platinum wire *d* is inserted so as just to touch the upper surface of the layer, and mercury is poured on to a depth of 1.5—2 cm. The two platinum wires are connected with the cell and bell shown in the figure, and the whole is ready for use. The temperature of the vessel *A* is slowly raised until the substance melts, allowing the mercury in the tube *B* to flow down and complete the circuit, ringing the bell and calling the operator's attention.

At temperatures above 250° C. a draught cupboard should be used; the applicability of the apparatus is limited to those substances that do not attack mercury appreciably. It can be used for a considerable range of temperature, the author having determined the melting points of ice and of saltpetre (338° C.) by its means.—B. B.

*Alteration of the Coefficient of Compressibility of Glass at different Temperatures.* E. H. Amagat. *Compt. Rend.* **110**, 1246—1249.

See under VIII., page 862.

# INORGANIC CHEMISTRY.—QUALITATIVE.

*On the Concentration of Solar Rays for Chemical Reactions.* J. W. Brühl. *Ber.* **23**, 1462.

MANY chemical processes are produced or accelerated by sunlight, and the author has therefore tried to increase the effect of sunlight by the concentration of rays by means of a concave mirror. As was expected, the experiments showed very favourable results, *e.g.*, in preparing zinc ethyl. The process is sometimes very tardy in its beginning, therefore the retort containing zinc and ethyl iodide was brought into the focus of a concave mirror of about 30 cm. diameter. The reaction then very readily began, and soon became so active that it was necessary to cool the retort. In about 15 minutes the process was finished and a large quantity of zinc ethyl was obtained by subsequent distillation in the oil-bath. The author thinks that this concentration of solar rays by means of a concave mirror will be of value also for other experiments, especially with halogen compounds. A glass lens may be used instead of a metallic concave mirror, but the action will be less effective, because of the considerable athermancy of glass.—H. S.

*The Action of Hydrogen Dioxide on the Oxides of Manganese.* A. Gorgeu. *Compt. Rend.* **110**, 857—859.

ANHYDROUS crystallised manganese dioxide decomposes hydrogen dioxide with comparative slowness. In presence of a slight excess of baryta the manganese dioxide suffers no change in composition; if, however, the hydrogen dioxide be acid, the dioxide of manganese is reduced more or less according to the amount of acid present. In two experiments, manganese dioxide, containing 98.5 per cent. of  $MnO_2$ , after treatment with three equivalents of hydrogen dioxide, acidified in one case with 0.05 per cent., and in the other with 0.20 per cent. of sulphuric acid, contained only 97 and 94.4 per cent. of  $MnO_2$  respectively. Hydrated dioxide of manganese acts far more energetically on hydrogen dioxide, the dioxide of manganese itself being in all cases considerably reduced. A sample containing 97.5 per cent. of  $MnO_2$  (reckoned on the anhydrous oxide), after decomposing three equivalents of hydrogen dioxide, contained only 70 per cent. of  $MnO_2$ . It appears, however, that reduction stops when the oxide arrives at the composition expressed by the formula  $Mn_2O_4$ ; in fact, this oxide is wholly unalterable by the action of hydrogen dioxide. It may be prepared by agitating moist manganous oxide in contact with air. Under these circumstances it might be thought that it were impossible, by means of hydrogen dioxide, to oxidise hydrated manganous oxide further than is expressed by the same formula  $Mn_2O_4$ , but this is not the case. In several instances hydrated manganous oxide treated with an excess of hydrogen dioxide was converted into an oxide containing appreciably more oxygen than the compound  $Mn_2O_3$ . The decomposing influence of manganous oxide on hydrogen dioxide is no doubt due to its strong basicity. The rate of decomposition is further accelerated by the higher oxide of manganese soon formed from the manganous oxide, and the high degree of oxidation attained may perhaps be ascribed to the large quantity of nascent oxygen thus produced. Anhydrous manganous oxide and precipitated manganous carbonate are not affected by hydrogen dioxide. The author believes to have proved that  $Mn_2O_4$  is slowly converted in contact with air or aerated water into  $Mn_2O_3$ .—H. T. P.

*The Action of Hydrogen Dioxide on Oxygen Compounds of Manganese. Part II.—Action on Permanganic Acid and Permanganates.* A. Gorgeu. *Compt. Rend.* **110**, 958—961. (See preceding abstract.)

In a solution containing either sulphuric acid or some other body, such as ammonium chloride, capable of dissolving manganese protoxide, hydrogen dioxide reduces all peroxides and acids of manganese to the state of manganese protoxide.

Hydrogen dioxide acting on a solution of pure permanganic acid decolourises it, oxygen being evolved and a peroxide of variable composition formed. Under certain circumstances the reaction corresponds to the equation—

If hydrogen dioxide be added to neutral or alkaline solutions of potassium and sodium permanganates the manganates and manganites are formed, the manganite being only slowly further reduced, while it exercises a rapid reducing action on the hydrogen dioxide itself. The barium salt, under similar conditions, gives the insoluble manganate and manganite. Silver permanganate yields a brown crystalline precipitate of silver manganite. In all the above reactions with neutral solutions, the hydrogen dioxide was poured into the permanganate solution, and the quantity of hydrogen dioxide decomposed by 1 equivalent of permanganic acid varied from 3 to 11 equivalents. If the permanganate be poured into the hydrogen dioxide, one equivalent seems to decompose an unlimited quantity of the dioxide. In 10 minutes one equivalent of permanganate decomposed from 150 to 300 equivalents of  $H_2O_2$ .—P. J. H.

*A New Characteristic Reaction of Hydrogen Peroxide.* G. Denigès. *Compt. Rend.* **110**, 1007.

A SOLUTION of ammonium molybdate in water (1:10) added to its own volume of concentrated sulphuric acid (1 cc. of each for example) gives, with traces of hydrogen peroxide, a yellow colouration, the intensity of which may be equal to that of a solution of an alkaline chromate or bichromate. Addition of sulphuric acid decreases the intensity of the colour in proportion to the quantity added, whilst addition of water causes a greater proportional decrease. One-tenth of a mgrm. of hydrogen peroxide may be thus detected. The ammonium molybdate may be replaced by the sodium salt, but without any advantage.

—J. W. L.

*Lead Phosphite and Lead Pyrophosphite; Qualitative Distinction between Pyrophosphites and Phosphites.* L. Amat. *Compt. Rend.* **110**, 901—904.

NEUTRAL lead phosphite was found to be extremely insoluble. If lead nitrate be added to lead phosphite in acid solution, an insoluble crystalline precipitate of *lead nitrophosphite*,  $PbHPO_3 + Pb(NO_3)_2$ , is thrown down.

By dissolving neutral lead phosphite in a hot concentrated solution of phosphorous acid, *acid lead phosphite*,  $PbH_2(PO_3)_2$ , is formed in well defined crystals, which decompose, in dilute solution, into phosphorous acid and the neutral phosphite of lead. If the acid phosphite be heated to 140° in a dry vacuum, one molecule of water is driven off, and *lead pyrophosphite*,  $PbH_2P_2O_5$ , is produced. In the presence of water this pyrophosphite becomes hydrated, but the acid phosphite formed gives rise immediately to the insoluble neutral phosphite and phosphorous acid.

When a solution of lead nitrate is added to a solution of sodium pyrophosphite, a crystalline precipitate of lead nitrophosphite is formed, and the solution becomes acid. This reaction takes place immediately in a *concentrated* solution even in the cold, but only after hours, or sometimes days if the solution be *cold* and *dilute*. On boiling, however, precipitation takes place immediately even in a dilute solution.

The reactions above described afford a ready method of distinguishing qualitatively pyrophosphites from phosphites.

Lead nitrate is added to the cold dilute solution; when phosphites are present, an immediate precipitate is formed, which is filtered off. The filtrate is then boiled; if pyrophosphites be present a precipitate will then be formed.

—P. J. H.

*New Mode of obtaining Crystalline Metallic Oxychlorides; the Oxychlorides of Copper.* G. Rousseau. *Compt. Rend.* **110**, 1261—1264.

See under VII., page 859.

*On the Action of Potassium Sulphate on Strontium Carbonate.* F. Kuklin. J. Russ. Chem. Soc. **22**, 322—326.

THE usual analytical method of separation of barium from strontium and calcium by boiling the solution of these metals with the mixture of potassium sulphate and potassium carbonate often fails and makes necessary a second boiling. The author, who undertook to find out the best condition under which the reaction is practically reliable, finds that strontium carbonate ceases to change into strontium sulphate when the proportion of sulphate to carbonate in the mixture is less than 55 : 1.

On the other hand the precipitation of strontium sulphate by the mixture is prevented when the proportion is not higher than 5 : 1.—N. W. T.

### INORGANIC CHEMISTRY.— QUANTITATIVE.

*Some Observations on the Relations of the Ferric and Aluminium Hydroxides, and of some Iron and Aluminium Salts to each other.* E. A. Schneider. Ber. **23**, 1349—1354.

See under VII., pages 857—858.

*Determination of Nitric Acid in Drinking Water by Schulze-Tiemann's Method.* L. Spiegel. Ber. **23**, 1361—1363.

SEVERAL years ago the author showed (Zeits. für Hygiene, 1887, 11, 163) that exact determinations according to Schulze-Tiemann's method can only be obtained if towards the end of the process the gas in the flask be expelled by a current of carbonic acid. The tests there described showed that an error of 3 per cent., or more, of the actual quantity of nitric acid present is the consequence of working according to Tiemann. In the new edition of his "Wasseruntersuchung," Tiemann does not, however, accept the proposals made in this direction, remarking (but without stating in figures his results of testing) that he has obtained just as good results by producing for a second time a partial vacuum in the flask. His first objection to the application of carbonic acid is that he considers it impossible to obtain this gas sufficiently free from air. This objection according to Spiegel is untenable, as he obtains a gas of quite sufficient purity by using small pieces of marble, which are placed some time in warm water before being put into Kipp's apparatus. The second objection to carbonic acid is, that it renders the apparatus more complicated in use, because of the necessity of a new tube being introduced. But this can easily be avoided by the following construction of the apparatus,

THE DETERMINATION OF NITRIC ACID.

which the author considers even more simple than that of Tiemann, because it dispenses with the partial vacuum. B, which is a tube terminating 2 cm. above the bottom of A, has at its upper end a bulb having a capacity of about 50 cc. The tube D is ground into the lower end of this bulb, the tube D being in connexion with the carbonic acid apparatus. The solution to be tested having been introduced

into the flask, carbonic acid is introduced through D, and the flask heated till the liquid boils gently; and this is continued until the gas going off through the tube C is free from air, which can be tested with a test tube containing caustic potash. The measuring tube is now placed over the delivery end of C, then 20 cc. of freshly-prepared and well-boiled ferrous chloride solution are introduced into the bulb forming the upper part of B, the solution flowing into the flask A when D is raised. In the same way, 40 cc. of concentrated and well-boiled hydrochloric acid are added. As soon as the liquid in the flask begins to boil again, the current of carbonic acid is stopped, and only towards the end of the reaction this gas is introduced again into the flask. The author mentions as a matter of course that the treatment with carbonic acid does not allow any unboiled reagents to be used in the test, and he is of opinion that in using these simple precautions this method gives more reliable results than any other.—H. S.

*An Improved Apparatus for the Estimation of Nitrates by Schulze-Tiemann's Method.* F. Scheiding. Chem. Zeit. **14**, 635—637.

THE nitric oxide produced by the decomposition of the nitrate is measured in a gas burette, consisting of a tube of about 100—180 cc. capacity, graduated in 0.2 cc. and enlarged at the top to a bulb fitted with a tap-funnel of about 20 cc. capacity. At the bottom the measuring tube is cut off straight, and is joined by a short piece of rubber tubing to the arrangement shown enlarged in the drawing.

THE ESTIMATION OF NITROGEN.

G is connected to the tube leading from the gas evolution flask, whilst L is joined by a long piece of rubber tube to the bottom of a flask of about 500 cc. capacity which serves to contain the caustic soda solution. A space of at least 10 cc. must exist between the 180 cc. mark of the burette and the top of the tube G. The straight portion of the burette is surrounded by a water jacket, in which hangs a thermometer, T. The burette is filled with a soda solution

of 1.25 sp. gr., and it is used until its density falls to 1.10—1.15. In carrying out an analysis, the nitrate to be analysed is washed with as little water as possible into the decomposition flask of about 200—250 cc. capacity. The soda solution is allowed to rise up to the tap 4, which is then closed. The air in the flask is now expelled through the tube 2, by briskly boiling the nitrate solution. The tap 5 is then closed, and tap 4 momentarily opened in order to expel the trace of air in tube 1 into the burette. The flame being removed, 20—25 cc. of a cold saturated solution of ferrous chloride are placed in the test tube and allowed to enter the flask by cautiously opening tap 5; 8—10 cc. of strong hydrochloric acid and two portions of water are passed into the flask in the same way. No trace of iron solution must remain in the tube 2. Whilst the contents of the flask are being gently warmed, the burette is filled by raising the soda-reservoir and opening the tap H to let out the air. The reservoir is then placed on the table, and a dish of cold water is put underneath the burette to cool the gas tube. As soon as the expansion of the rubber tubing indicates the existence of pressure in the flask, the tap 4 is opened and the gas driven over into the burette by evaporating the solution in the flask almost to dryness. Tap 4 is then closed and No. 5 opened. During the course of the distillation, the cooling water is adjusted to the same temperature as that indicated by a thermometer hung close to the bulb of the burette. When the temperature has remained constant for about 10 minutes, the gas volume may be read off. In accurate analyses it is necessary to equalise the densities of the soda solution in the burette and flask by sucking a quantity of fresh soda solution into the burette through the tap H. The results are calculated by means of the following formula:—

$$\text{Per cent. N} = \frac{V(b-f) \cdot 273 \times 0.6281}{760(273+t)} \times \frac{100}{g};$$

Where—

V = Volume as read off.

b = Height of barometer in mm. reduced to 0° C.

f = Tension of vapour from soda solution.

g = Weight of substance taken in mgms.

0.6281 = Weight of 0.5 cc. of nitrogen at 0° C. and 760 mm. in mgms.

$$\text{Now } \frac{273 \times 0.6281 \times 100}{760} = 22.562;$$

and if  $\frac{22.562}{273+t} = K$ , then

$$\text{Per cent. N} = \frac{V(b-f)K}{g};$$

Or  $\log. \text{ per cent. N} = \log. V + \log. (b-f) + \log. K - \log. g$ .

The values of  $K = \frac{22.562}{273+t}$  at different temperatures  $t^\circ$ , are given in the following table:—

$t^\circ \text{ C.}$	K.	$t^\circ \text{ C.}$	K.	$t^\circ \text{ C.}$	K.

*On the Reduction of Nitric Acid to Ammonia, and on the Estimation of Nitric Acid.* E. Boyer. *Compt. Rend.* 110, 954—956.

The reduction of nitric acid by means of zinc and hydrochloric acid generally gives rise to oxides of nitrogen and nitrogen, as well as to ammonia, and hence all attempts to estimate nitric acid by this reaction have hitherto failed. The author has determined the conditions under which ammonia only is produced, and describes a method for estimating nitric acid under these conditions.

The solution to be estimated must not contain more than 3.17 per cent. of  $\text{N}_2\text{O}_5$  (corresponding to 5 per cent. of pure  $\text{NaNO}_2$ ). Five grms. of granulated zinc, in pieces the size of a pea, are introduced into the bottom of a test tube 30 centimetres long, 2.2 centimetres in diameter, and provided with a lip, and a quantity not exceeding 10 cc. of the nitrate solution is then poured from a pipette into the bottom of the tube, and 5 cc. of hydrochloric acid, of density 1.19, are poured down the sides to wash down any traces of nitrate. The tube is then agitated by a circular motion till the evolution of hydrogen ceases; a fresh quantity equal to 5 cc. of hydrochloric acid is then added, which completes the reduction of the nitric acid. After 10 minutes this reduction is complete, even though hydrogen continue to come off. No loss takes place by projection or evaporation, owing to the length of the tube. The contents of the tube and wash-water are introduced into a flask, the zinc precipitated by potash, 2 grms. of caustic magnesia added, and the liquid distilled with an ordinary Schloesing condenser, the ammonia being driven off into a known quantity of standard acid. Magnesia is used instead of an excess of potash or soda, as both of these bases give rise to double salts with ammonia, which only decompose after a considerable time.

To ensure success, the precautions described are absolutely necessary; if the quantities of solution taken be altered, or the density of the acid be less than 1.19, oxides of nitrogen will be formed, and show their presence by the yellow colouration of the liquid. The liquid should remain perfectly colourless.—P. J. H.

*A New Method of Estimating the Free and Combined Carbon in Iron and Steel.* O. Pettersson and A. Smith. *Ber.* 23, 1401—1402.

From 0.4 to 0.8 gm. of the metal in the form of a single rolled or hammered piece is dissolved in fused potassium bisulphate, by which operation—requiring from 5 to 12 minutes—the iron is converted into ferric sulphate, and the combined carbon oxidised into carbonic anhydride which is evolved together with sulphurous anhydride. These gases are led into and absorbed by a mixed solution of sodium and barium hydrates, which solution is then treated first with potassium permanganate to oxidise the sulphite to sulphate, and then with nitric acid to liberate the carbonic anhydride, which is then estimated by the method described in the following abstract. This gives the combined carbon. The graphite, which remains unchanged in the melt, is obtained by dissolving the sulphates in warm hydrochloric acid, and filtering through asbestos in a small platinum filter. The whole is dried, gently ignited, and weighed, then placed in a glass tube and ignited in a stream of air laden with nitrous fumes, and again weighed. The difference between the two weighings represents the graphite.

—A. W.

*A Method for Estimating Carbonic Anhydride.* O. Pettersson. *Ber.* 23, 1402—1406.

This apparatus serves for the estimation of carbonic anhydride either combined or in solution. The solid or solution is introduced into the flask B, and the carbonic anhydride is liberated by means of acid and by boiling, and is measured in D. A piece of iron or aluminium wire is placed in B so as to furnish a small stream of hydrogen. This serves a double purpose, firstly to sweep out the dissolved gas, and secondly to prevent violent ebullition. At starting, the liquid containing carbonic anhydride is introduced into B

up to the mark *x*, the connections are then made, acid is poured into A, F lowered and the acid allowed to flow in through *a* until the mark *y* is reached, when *a* is closed. F is now considerably lowered so as to exhaust C, and *b* is then closed. The reservoir F is raised until the level of the mercury is the same in the two tubes, *d* is opened, the level of the alkali in the Orsat tube E is accurately adjusted to the mark on the capillary and the volume of the air in D noted. The air is now passed into E until the carbonic anhydride is absorbed and is again measured as before. Unless the liquid was rich in carbonic anhydride the result obtained by these first measurements would only represent the carbonic anhydride contained in the ordinary atmosphere. The distillation of the liquid in B is now proceeded with, the bulk of the air in D is expelled through *c*, the rest is transferred to E until the next measurement; F is lowered and *b* partially opened to allow a quantity of gas to pass over. When sufficient is in D, *b* is closed and the carbonic

anhydride measured as before. This operation is repeated and the evolution of hydrogen continued until the gas shows no contraction after treatment with the potash in E. The various contractions are then added together and give the total result.—A. W.

*The Estimation of Phosphorus in the "Basic" Siemens Steel Bath.* W. Galbraith. Paper read before the Iron and Steel Institute, May 1890.

See under X., page 864.

*The Reciprocal Action of Mercurous and Alkaline Haloid Salts.* A. Ditte. Compt. Rend. **110**, 1330—1333.

This is a thermo-chemical paper, in which the author describes the results of his investigations on the interaction of mercurous and potassium haloid salts. Potassium cyanide decomposes mercurous chloride in the cold in the following manner:—

Potassium iodide acts similarly.

In the case of chloride and bromide of potassium heat is absorbed.

The reactions which take place between mercurous bromide and potassium cyanide, iodide, and bromide are similar to the above, the nett amounts of heat disengaged being + 15·4, + 4·3, and - 12·4 calories respectively. In the case of potassium chloride the maximum thermal effect corresponds to the following equation:—

This reaction is certainly endothermic, since the heat of solution of mercuric bromide in an excess of potassium chloride is less than the difference between the heats of formation of mercuric and mercurous bromides. Mercurous iodide is decomposed by potassium cyanide in the same way as the chloride, the heat liberated being + 5·6 calories. By the action of potassium iodide, bromide, and chloride on mercurous iodide, mercury is liberated, the mercuric iodide formed being simply dissolved in the excess of alkaline haloid salt, without any double decomposition taking place. The amounts of heat are - 8·0, - 13·6, and - 13·6 calories respectively. The heat of solution of mercuric iodide in potassium bromide and chloride is insignificant. The fact that those of the above reactions which are endothermic are realisable in practice may be easily understood, when it is considered that mercurous haloid salts are decomposed by water alone, especially when boiling and often changed, into mercury and mercuric salts. In the presence of an alkaline haloid salt, the mercuric compound forms with it a double salt. The equilibrium existing between the mercurous and mercuric compounds, the mercury and the water is thus destroyed, and a fresh portion of mercurous salt is decomposed in order to restore it. In this manner the action goes on until only mercury is left.—H. T. P.

*The Electrolysis of Metallic Phosphates in Acid Solution.* E. F. Smith. Amer. Chem. J. **12**, 329—336.

THE course pursued in the preparation of the solutions for electrolysis was to first precipitate the metal with an excess of di-sodium phosphate, dissolving the compound obtained in a measured volume of free phosphoric acid, and then exposing the liquid to the action of currents of known

THE ESTIMATION OF CARBON DIOXIDE.

strength. Mercurous, lead and bismuth phosphates being nearly insoluble in phosphoric acid were therefore not available for these experiments.

**Copper.**—To a solution containing 0.0996 gm. of metallic copper as sulphate, 10 cc. of  $\text{Na}_2\text{HPO}_4$  (sp. gr. 1.0358) and 3.5 cc. of  $\text{H}_3\text{PO}_4$  (sp. gr. 1.347) were added. The precipitated copper phosphate dissolved in 0.5 cc. of acid so that the deposition of metal occurred in the presence of 3 cc. of free phosphoric acid. The total dilution with water amounted to 125 cc. The current employed gave 0.15 cc. of electrolytic gas per minute. The current in two other experiments was increased to 0.5 cc. electrolytic gas per minute. Strong currents deposit metallic iron and other metals from their phosphates in phosphoric acid solution. The results obtained appear very satisfactory.

**Copper from Iron.**—A solution containing as before 0.0996 gm. of copper with the addition of 0.1700 gm. of metallic iron, to which 30 cc. of di-sodium phosphate and 4.5 cc. of phosphoric acid solution were added, was decomposed by a current giving 0.6 cc. of gas per minute. The whole of the copper was deposited.

**Copper from Aluminium.**—A copper solution containing aluminium was treated as above with a current giving 0.3 cc. of gas per minute; the copper deposited weighed 0.0995 gm.

**Copper from Chromium.**—A solution similarly treated with the same strength of current as in the separation of the aluminium, deposited 0.0994 gm. of the copper, and converted the chromium into chromic acid.

**Copper from Zinc.**—A solution containing the same quantity of copper with the addition of 0.1500 gm. of zinc, deposited 0.0993 gm. of copper. The strength of current was 0.15 cc. of electrolytic gas.

**Copper from Cobalt.**—With 0.0968 gm. of cobalt, solution as before, with a current of 0.22 cc. of gas, the copper deposited was 0.0995 gm.

**Copper from Nickel.**—The nickel (0.1105 gm.) was present as chloride, the other conditions being the same as in the preceding example. The deposit of copper weighed 0.0996 gm.

In all the above experiments the copper deposited rapidly from cold solutions. The deposition was allowed to continue all night. Before interrupting the current the acid liquid was siphoned off and replaced by water. The deposits were washed with cold and hot water.

**Cadmium.**—Ten cc. of cadmium sulphate (= 0.1827 gm. of Cd) were precipitated by an excess of di-sodium phosphate. The phosphate dissolved in 1.5 cc. of phosphoric acid ( $\text{H}_3\text{PO}_4$ ). The current gave 0.6 cc. of gas.

Two determinations with the strength of current yielded (a) 0.1839 gm. and (b) 0.1820 gm. The cadmium deposit in (a) showed a little sponginess and did not form as rapidly as the copper. It was found advisable towards the close of the experiment to increase the current strength. With a current of 0.40 cc. the deposits obtained were (a) 0.1828 gm. and (b) 0.1833 gm.

**Cadmium from Zinc.**—A solution containing 0.1827 gm. of cadmium and 0.1500 gm. of zinc treated with di-sodium phosphate and phosphoric acid and diluted to 125 cc., deposited 0.1820 gm. of cadmium in 12 hours when acted upon in the cold with a current evolving 0.35 cc. of gas per minute.

**Cadmium from Nickel.**—The experiments were conducted as above and gave good results. The separation of cadmium from iron, chromium and aluminium gave equally good results. The solution in these cases was made up to 100 cc.

The separation of copper from the metals mentioned in connexion with it, is not attended with any difficulty, but with cadmium compliance with the conditions given is absolutely necessary, as the results otherwise vary. In solutions containing free phosphoric acid, cadmium is usually inclined to sponginess, so that concentration of liquid should be avoided, and the poles of the acting

battery should not approach too closely to each other. The most favourable separation was found to be  $1\frac{1}{4}$  in., and the proper dilution of the liquid 100—150 cc.

**Copper from Cadmium.**—A solution containing 0.2452 gm. of copper and 0.1827 gm. of cadmium as sulphates with 20 cc. of di-sodium phosphate and 10 cc. of phosphoric acid diluted to 125 cc., deposited in two experiments 0.2451 and 0.2452 gm. respectively of copper, with a current giving 0.10 cc. of gas per minute. With a current of 0.2 cc. the deposit weighed 0.2451 gm.

Silver phosphate, in a phosphoric acid solution, when electrolysed gives a deposit of spongy metal. When the phosphate is dissolved in the least possible quantity of ammonia, the deposit is coherent.

Manganese is not deposited as dioxide at the positive pole if the phosphate strongly acidified with phosphoric acid be electrolysed. The author utilises these conditions to effect the separation of manganese and copper.—J. B. C.

#### *The Dry Assay of Tin Ores.* Part I. H. O. Hofman. Technology Quarterly, **3**, 112—143.

THE author has studied practically the application of the various methods for the dry assay of tin to the black tin-stone of the Black Hills, where its occurrence is different to that in other parts of the world. He prepared a large quantity of the pure cassiterite for his experiments, and by a careful process of pulverising, screening, roasting to free from sulphur and arsenic, treating with acids and finally washing, a product was obtained which gave by wet assay 86.24 per cent. of  $\text{SnO}_2$ , or 67.84 per cent. of Sn. This material was then subjected to various modifications of the three usual methods of assay. The German method (the reduction with charcoal, black flux, borax and salt) when carefully carried out gave very good results, averaging 67.58 and 67.46 per cent. of Sn. The method was varied by prolonging the time of fusion, using chalk-lined crucibles, and by heating with charcoal first and then adding the fluxes, but in no case were such satisfactory results obtained. The method of fusion with fluorspar, however modified, gave very bad results. The cyanide method when pure cyanide was used (98 per cent. of KCN and 2 per cent. KOCN) gave results averaging 67.30 per cent. Various modifications were tried, such as using salt, potassium carbonate or charcoal with the cyanide and employing lined crucibles, but in every case worse results were obtained. Potassium carbonate lowers the results more and more as the amount present increases, hence, in the assay of tin ore common cyanide should be avoided. The cyanide "pure for gold platers" (92 per cent. of KCN, 5 per cent. of KOCN, and 3 per cent. of other salts) gave average results of 67.10 per cent., and the common fused variety 60.76 per cent. Full details of the experiments and results are given in the paper. The author finds that no advantage is obtained by lining the crucibles in any way, equally good and sometimes better results being obtained in the ordinary Battersea crucible.

—A. W.

#### ORGANIC CHEMISTRY.—QUALITATIVE.

##### *The Detection of Noxious Mineral Substances in Wine.* L. Liebermann. Chem. Zeit. **14**, 635.

**Detection of Copper, Lead, and Arsenic.**—100 cc. of the wine are evaporated down to one-half, 10—15 cc. of hydrochloric acid then added, and the mixture diluted to 100 cc. with strong sulphuretted hydrogen water. In absence of metals of the second group, the wine remains absolutely clear and is unaltered in colour. In presence of these metals a more or less distinct precipitate is formed and the wine is discoloured. The precipitate is filtered off and washed, first with water and then with alcohol. When its quantity is small the paper is only covered with a yellowish, brownish or blackish film. In presence of 0.01 per cent. of copper, lead, or arsenious acid, the reaction is quite strong, and even when only 0.001 per cent. is present, a distinct reaction is obtained. In order to identify the

separate metals, the precipitate is dissolved in dilute nitric acid, and the solution boiled and filtered. In the filtrate, lead is tested for by means of sulphuric acid. The solution freed from lead is boiled to expel nitric acid. In one portion of this solution the copper is identified by adding ammonia or potassium ferrocyanide; to the other portion a little pure zinc is added, and the hydrogen arsenide thus produced is detected by its action on a drop of silver nitrate solution spread on filter-paper. A citron-yellow spot surrounded by a black ring is formed; on the addition of a few drops of water the spot turns black all over.

**Detection of Zinc.**—The wine is evaporated down to one-half, made alkaline with ammonia, and then acid by the addition of an excess of acetic acid, and finally diluted to its original bulk with strong sulphuretted hydrogen water. In presence of zinc, a grey, or in the case of red wines, a violet-grey precipitate is formed. The thoroughly washed precipitate is dissolved in dilute hydrochloric acid, the solution being boiled to expel sulphuretted hydrogen. The solution is again filtered and mixed with excess of caustic potash solution. The liquid is filtered through glass-wool or very closely-woven linen. In the filtrate, ammonium chloride produces in the presence of zinc a precipitate soluble in excess of ammonium chloride.—H. T. P.

**Detection of Diresorcinol in Synthetic Phloroglucinol.**  
J. Herzog and S. Zeisel. Chem. Zeit. 14, 1064.

DIRESCORINOL, when dissolved in concentrated sulphuric acid and treated with glacial acetic acid, and the mixture heated, gives an intense violet colour. By this test the fact has been established that phloroglucinol purified according to Will's method still contains diresorcinol, whilst that prepared according to Skraup was free from it. Phloroglucinol prepared from phloroglucinol acetate was pure, even when the latter was made from material containing diresorcinol.—W. M.

**The Acidity of Vegetable Oils.** Holde. Mitt. königl. techn. Versuchs. 1890, 78—82.

THE author examined many samples, particularly of rape oil, both for mineral and free fatty acid. The former, together with that present as sulphonic acids in the oil, was recognised in the usual way by shaking and heating with water. He records the familiar fact that mineral acids are seldom present even in traces in properly refined oils. More interesting results are afforded by a lengthy table, the mean values of which show an average percentage of free fatty acid in unrefined rape oil of 0.15 per cent., calculated as sulphuric anhydride, corresponding to 1.08 when reckoned as oleic acid, while the numbers for refined rape oil are 0.35 and 2.45, and for cotton-seed oil 0.78 and 5.51. In connexion with these last figures it must be stated that certain of the samples were abnormally acid and thus raised the average.

Further experiments were made to ascertain the rate of increase of acidity suffered by oils exposed to the air for considerable periods. In general, the lapse of about a year and a half caused an increase of 20—40 per cent. of the original acidity in the case of an oil with a low proportion of free fatty acid, while in one instance of a cotton-seed oil, very acid and rancid besides, the increase was from 1.46 per cent., calculated as sulphuric anhydride, in June 1889, to 2.82 in March 1890. (These figures can be very approximately converted into percentages of oleic acid by multiplication by 7.)—B. B.

**New Reactions of Albuminoids.** C. Reichl. Monatsh. 11, 155—165.

IT was shown a short time ago that a blue colouration is produced when an albuminoid is treated with dilute sulphuric acid, ferric sulphate, and an alcoholic solution of benzaldehyde or salicylaldehyde. In these reactions the ferric sulphate plays the part of an oxidising agent and can be replaced by very dilute nitric acid, mercuric oxide, &c. The blue condensation-product is the sulphate of a base; it is decomposed by alkalis with separation of a brownish

precipitate which dissolves in acids yielding a blue or bluish-green, and in alkalis giving a yellowish solution. The reaction seems to be caused either by the skatol- or the indol-group of the albuminoid molecule, most probably by the former, since skatol itself gives colour reactions very similar to those produced in the case of albuminoids.

Benzyl alcohol, and resins containing derivatives of benzyl alcohol, Peru- and Tolu-balsam, for example, give a bluish-green or bluish-violet colouration with ferric sulphate, dilute sulphuric acid, and an albuminoid, amygdalin; on the other hand, gives no colouration unless more concentrated sulphuric acid is employed.

The reaction with salicylaldehyde is carried out as follows: The albuminoid in a solid condition is treated with one drop of a 0.5 per cent. alcoholic solution of salicylaldehyde, the alcohol is allowed to evaporate, and several drops of dilute sulphuric acid containing ferric sulphate are added; after a short time eggs, blood-, and plant-albumen, blood-fibrin, and casein give a violet-blue, legumin a brownish-violet, and plant fibrin a brownish-yellow colouration; sheep's wool and animal membrane are coloured bluish-violet under the same conditions. When the albuminoid is in solution a drop of a 0.5 per cent. alcoholic solution of salicylaldehyde and an equal volume of concentrated sulphuric acid are added, the mixture is cooled, but without shaking, and then a drop of ferric sulphate solution is added; a blue to violet zone is observed after a longer or shorter time according to the diluteness of the solution.

The oil of *Spica ulmaria* gives the same reactions as salicylaldehyde; with salicin, populin, and saligenin the colouration is produced more slowly and is less intense.

Anisic aldehyde, under the conditions described above, gives with egg-albumen, plant-albumen, and casein a violet, with blood-albumen and sheep's wool a violet-red, with blood-fibrin a blue, with legumin a brownish-violet, and with plant-fibrin a reddish-yellow colouration, the reactions being produced more quickly than is the case with benzaldehyde and salicylaldehyde. Anethol, anisol, Indian anise oil, esdragon oil, and fennel oil react like anisic aldehyde, only more feebly; if mercuric oxide be used instead of ferric sulphate the colourations are more intense.

Vanillin, under the same conditions, gives a violet or violet-blue colouration with egg-, blood-, and plant-albumen, casein, blood-fibrin, sheep's wool, and animal membrane, whilst with legumin it gives a brownish red, and with plant-fibrin a pale violet colouration. Vegetable products containing vanillin, such as vanilla, assafetida, &c., give the same reactions.

When wood, which according to Singer always contains vanillin, is heated with a dilute sulphuric acid solution of egg-albumen containing a little ferric sulphate, it becomes green and then darkens, the solution turning violet; the wood is probably coloured by the sulphuric acid, but the colouration of the solution is probably due to the action of the vanillin on the albumen.

Piperonal gives the same colourations as vanillin; para-cuminaldehyde and cinnamic aldehyde give a slight colouration with some, but no reaction with other albuminoids, whilst those obtained with furfuraldehyde are very feeble.

The various albuminoids do not all give these colour reactions with the same intensity; in the case of legumin and plant-fibrin, for example, the colouration is sometimes difficult to detect or is not produced at all. Piperonal, vanillin, anisic aldehyde and cinnamic aldehyde produce a colouration immediately when the albuminoid is in the solid condition or in moderately concentrated solution, but with salicylaldehyde, benzaldehyde, furfuraldehyde, and cuminaldehyde the colouration is not produced for some time; a 0.1 per cent. solution of an albuminoid requires an hour, and more dilute solutions an even longer time before a colouration is produced.

The reactions with aldehydes are not as delicate as some of the older ones, except when the albuminoid is in a solid state, because there is a maximum proportion between the albuminoid and the acid solution which should not be exceeded; this proportion is 1 part of albuminoid to 6,000 parts of dilute sulphuric acid in the case of salicylaldehyde, 1 to 10,000 in the case of benzaldehyde, and 1 to 40,000 in

the case of anisic aldehyde, vanillin, and piperonal. Aqueous solutions should seldom contain more than 1 part of albuminoid in 3,000 parts of water or the reaction will not take place.

Hydrogen peroxide, in presence of dilute sulphuric acid, gives after a short time a reddish colouration with albuminoids, but the colouration disappears on the addition of ferric sulphate.—F. S. K.

### Tests for Cocaine Hydrochloride.

See under XX., page 888.

## ORGANIC CHEMISTRY.—QUANTITATIVE.

*The Influence of Solvent or Medium on the Speed of Reaction.* N. Menshutkin. J. Russ. Chem. Soc. **22**, 347—358 and 393—409.

In his previous investigation on the same subject (J. Russ. Chem. Soc. **19**, 642) the author had come to the following conclusions:—

(1) The speed of a reaction may vary considerably, being carried on in different solvents or mediums; (2) the chemical process could not be considered independently of the solvent or medium in which it is carried on; (3) the latter enters in every chemical reaction with a certain coefficient.

The present investigation concerns the details of the same subject under two principal aspects; *a*, as to the influence of different solvents on a given reaction; and *b*, as to the speed of different reactions in a given solvent.

The author has chosen the reaction of triethylamine with ethyl iodide as most convenient for the purpose. It was carried on in 15 volumes of different liquid solvents which are chemically quite indifferent to either of the reagents. It has been found that under this condition, at the temperature of 100°, and within the same space of time considerably different amounts of tetra-ethylammonium iodide,  $(C_2H_5)_4NI$ , are formed.

These results are expressed in the adjoining table; the first column showing 23 different solvents, the second containing the constants of speed of the reaction, the third, the relative speed of reaction in the corresponding solvent, taking the lowest one, the case of hexane, as 1·0, thus illustrating the quickening influence of different solvents; while the fourth shows the same relative speed of the reaction, taking the greatest speed, in case of benzyl alcohol, as 100, thus illustrating the retarding influence of the solvents.

This table shows that a given reaction goes on in benzyl alcohol 742 times quicker than in hexane; this being the maximum difference of speed shown in the table, the author thinks there may be expected still more favourable solvents for the reaction in alcohols and ketones of the naphthalene series.

The author finds the cause of these differences in the composition and structure of the solvent. The illustrations to be found in the same table. (*a*.) In hydrocarbons and simple ethers the reaction goes on the slowest; quicker in mixed ethers, still quicker in ketones, but the quickest in alcohols (and of course in acids, which could not be tried in this case).

### I.

	Relative Speed.
Hexane, $C_6H_{14}$ .....	1·0
Ethyl ether, $C_2H_5.O.C_2H_5$ .....	4·2
Ethyl acetate, $C_2H_5.O.CO.CH_3$ .....	123·9
Ethyl alcohol .....	203·9
Acetone, $CH_3.CO.CH_3$ .....	337·7

### II.

	Relative Speed.
Benzene, $C_6H_6$ .....	38·2
Phenetol, $C_6H_5.O.C_2H_5$ .....	117·7
Ethyl benzoate, $C_2H_5.CO.OC_2H_5$ .....	173·9
Acetophenone, $C_6H_5.CO.CH_3$ .....	718·7
Benzyl alcohol .....	742·2

Thus the compounds containing hydroxyl (HO), *i.e.*, alcohols, acids, and their derivatives, as mixed ethers and ketones, appear to be the most favourable for the speed of reactions.

(*b*.) Members of the same homologous series, of the same structure, used as solvents, affect the reaction as follows: the greater the molecular weight of the solvent, the smaller is the speed of the reaction.

### I.

	Relative Speed.
Methyl alcohol, $CH_3.OH$ .....	286·6
Ethyl alcohol, $C_2H_5.OH$ .....	203·3
Isobutyl alcohol, $C_4H_9.OH$ .....	143·8

### II.

	Relative Speed.
Anisol, $C_6H_5.O.CH_3$ .....	223·9
Phenetol, $C_6H_5.O.C_2H_5$ .....	117·7

(*c*.) The less saturated is the solvent the greater is the speed of the reaction. The comparison of allyl and aromatic compounds with those corresponding of the paraffin series fully illustrate this.

	Relative Speed.
Ethyl alcohol, $\text{C}_2\text{H}_5\text{CH}_2\text{OH}$ .....	203.3
Allyl alcohol, $\text{CH}_2\text{CH}=\text{CH}_2\text{OH}$ .....	240.5
Hexane, $\text{C}_6\text{H}_{14}$ .....	1.0
Benzene, $\text{C}_6\text{H}_6$ .....	38.2
Ethyl ether, $\text{C}_2\text{H}_5\text{O.C}_2\text{H}_5$ .....	4.2
Phenetol, $\text{C}_6\text{H}_5\text{O.C}_2\text{H}_5$ .....	117.7
Ethyl acetate, $\text{CH}_3\text{CO.O.C}_2\text{H}_5$ .....	123.9
Ethyl benzoate, $\text{C}_6\text{H}_5\text{CO.O.C}_2\text{H}_5$ .....	143.9
Acetone, $\text{CH}_3\text{CO.CH}_3$ .....	337.7
Acetophenone, $\text{CH}_3\text{CO.C}_6\text{H}_5$ .....	718.7
Ethyl alcohol, $\text{C}_2\text{H}_5\text{OH}$ .....	203.3
Benzyl alcohol .....	742.2

There is only one observation supporting author's expectation as to a still greater speed of the reaction in solvents of naphthalene series:—

	Relative Speed.
Bromo-benzene .....	150
$\alpha$ -Bromo-naphthalene .....	627

(d.) The substitution of chlorine for hydrogen increases the speed of the reaction; still more so the substitution of bromine and iodine.

	Relative Speed.
Benzene, $\text{C}_6\text{H}_6$ .....	38.2
Chloro-benzene, $\text{C}_6\text{H}_5\text{Cl}$ .....	128.0
Bromo-benzene, $\text{C}_6\text{H}_5\text{Br}$ .....	158.0
Hexane, $\text{C}_6\text{H}_{14}$ .....	1.0
Propyl chloride, $\text{C}_3\text{H}_7\text{Cl}$ .....	38.0

The substitution of different organic groups for hydrogen in benzene supplied the following results:—

	Relative Speed.
$\text{C}_6\text{H}_6$ .....	38.2
$\text{C}_6\text{H}_5(\text{OC}_2\text{H}_5)$ .....	117.7
$\text{C}_6\text{H}_5(\text{CO.O.C}_2\text{H}_5)$ .....	143.9
$\text{C}_6\text{H}_5(\text{O.CH}_3)$ .....	223.9
$\text{C}_6\text{H}_5(\text{CO.OCH}_3)$ .....	718.7
$\text{C}_6\text{H}_5(\text{CH}_2\text{OH})$ .....	742.2

This table shows that the groups containing oxygen, being substituted for hydrogen, make the solvent more favourable for the reaction than those containing chlorine and bromine.

The physical properties of the solvent have apparently very little importance in this respect. The researches of Kobilansky (*Z. f. phys. Chem.* 4, 29) show that hydrocarbon and simple ether solutions are the worst conductors of electricity, while weak alcoholic solutions are the best conductors.

The above results led the author to the conclusion that in case of a weak reaction it is advisable to use as solvents alcohols and ketones, while energetic reactions require to be carried on in hydrocarbon and ether solutions.

The same results may be applied to the chemical reactions between liquid compounds without any solvents; the excess of either of the reagents may be considered as such. To illustrate this, a series of experiments were made on the reaction of acetic acid on aniline:—

Parts of Aniline for 1 Part of Acetic Acid.	Relative Speed.
1 .....	34.7
2 .....	28.7
3 .....	23.5
4 .....	17.1

Parts of Acetic Acid for  
1 Part of Aniline.

1 .....	34.7
2 .....	57.3
4 .....	78.1

Thus, the excess of the aniline decreases the speed of the reaction, while the excess of the acid increases it.—N. W. T.

### The Flashing Point of Lubricating Oils. A. Martens Mitt. königl. tech. Versuchs. 1890, 71—78.

A SIMPLE plan used by Treumann, of Hanover, for determining the flashing point of lubricating oils—the apparatus consisting merely of a capsule placed in a hemispherical sand-bath, to protect it from air currents, the light being applied from time to time to the uncovered surface of oil in the capsule—is compared with the elaborate method in vogue at the Versuchsanstalten, in which the modified Abel-Pensky apparatus (this Journal, 1889, 734) is employed. The results show that for many practical purposes the simpler process is sufficiently accurate, though suffering from the inherent disadvantages of all “open-test” methods. A communication from Treumann incorporated in the paper shows that discrepancies are possible even with the modified Abel-Pensky, concerning the constancy of the results of which several points are at issue between him and the author.—B. B.

### Action of Reducing Agents upon Gallic Acid and Tannins. C. Böttlinger. Annalen. 258, 252—260.

METALLIC sodium was added in small portions to the solution of gallic acid in absolute alcohol. No reduction products were obtained. Tannic acid similarly treated appeared to undergo simple hydrolysis, the yield of gallic acid amounting to 60 per cent. of the weight of the tannin. Tannin dissolved in amyl alcohol, and heated with the metal at the boiling temperature of the alcohol, undergoes partial resolution into gallic acid, a portion combining with the alkyl to form ethereal derivatives. Acetoquercitanic acid is similarly attacked.

The results of the investigation in respect of its main object, which was to prepare reduction products of these compounds, were negative.—C. F. C.

### Derivatives of Diphenylhydrazine. R. Stabel. Annalen, 258, 242—251.

Diphenylhydrazine has been obtained by the author by distillation under diminished pressure (40—50 mm. at 220°) and recrystallising from petroleum spirit, in colourless tabular crystals belonging to the monoclinic system and melting at 34.5°.

*Compounds with the Sugars.*—The hydrazones are well crystallised bodies only slightly soluble in water.

*Glucosodiphenylhydrazine.*—To prepare this compound 1 part of grape sugar is dissolved in a small quantity of water and added to an alcoholic solution of the base (1.5 parts). The mixture is heated for 2 hours on the water-bath, the alcohol evaporated off, and ether is added to the solution, to remove the excess of base. The aqueous portion solidifies to a crystalline magma. The yield of hydrazone amounts to 75 parts of the theoretical. It is best purified by recrystallisation from its solution in hot water, this property being characteristic of the compound. In the pure state it melts at 161°—162°. The formation of this hydrazone affords an excellent method of identifying dextrose in presence of levulose. In cases where the solution cannot be heated the separation of the hydrazone may be completed by allowing the mixture to stand 2—3 days at the ordinary temperature.

*Mannosodiphenylhydrazine.*—This compound closely resembles the above, melting at 155° to a clear yellow liquid.

*Galactosodiphenylhydrazine* is also similar in properties to the above; melting point 157°.

*Rhamnosodiphenylhydrazine* is formed by heating the reagents in alcoholic solution 3—4 hours; or in a sealed tube at 100° for 2 hours. The product crystallises from its solution in hot water in colourless silky needles (melting point 134°).

### Furfurandiphenylhydrazine—

is rapidly formed when the aldehyde and base are brought together in equal molecular proportions. It crystallises from aqueous alcohol in yellowish needles (melting point 90°).

*Salicylaldehydediphenylhydrazone* is similarly obtained, crystallising from its solution in alcohol (80 per cent.) in colourless needles (melting point  $138^{\circ}5$ ).

*Diphenylhydrazine* and *Carbondisulphide* readily react with formation of diphenylthiocarbazine acid—

which crystallises from its solution in the disulphide in long golden yellow prisms (melting point  $109^{\circ}$ ). On heating with diphenylhydrazine the thio-urea of this base is formed—

—C. F. C.

*The Curves of Boiling Temperatures as a Function of the Chemical Nature of the Bodies. Simple Rule for the Determination of the Boiling Points of Organic Bodies at Reduced Pressures.* M. Wildermann. Ber. **23**, 1254—1264.

It is to see whether a relation exists between the pressure and the curves of boiling temperatures on the one hand, and the chemical nature of bodies on the other, the author has compared 20 different homologous series, and has found that within large limits of pressure the proportion of the absolute boiling temperature at M mm. pressure to that at N mm. pressure is almost the same for all members of a homologous series. Therefore the equation is practically correct

$\frac{T_a p}{T_a P} = \frac{T_b p}{T_b P} = \frac{T_c p}{T_c P} = D_1$  where  $a, b, c$  are different members of a homologous series,  $p$  and  $P$  less and higher pressures. This formula shows, first that  $T_a p = T_a P \times D_1$ , viz., that the absolute boiling temperature of a body at a lower pressure  $p$  is equal to its absolute boiling temperature at a higher pressure  $P$  multiplied by  $D_1$ , or by the proportion  $\frac{T_b p}{T_b P}$ , which may be calculated from any other member of the same homologous series. Secondly,  $T_a p : T_b p = T_a P : T_b P$ , viz., the relating of the absolute boiling temperatures of two members of a homologous series is almost the same at any pressure (between 12 mm. and 2 atmospheres). Thirdly—

$$\frac{T_a p - T_a P}{T_b p - T_b P} = \frac{T_a p}{T_a P} = \frac{T_b p}{T_b P}$$

viz., the difference of temperatures between two boiling points of a member of a homologous series at two different pressures is to the corresponding difference of temperatures of another member as the absolute boiling temperatures of these members are to each other at a pressure of M mm.

The author shows that these formulae may be used for the fatty acid series, partly for the aromatic series, and also for certain isomeric bodies, such as isomeric acids, alcohols, &c. He does not claim for these formulae any theoretical value, but has given them as mere rules for practical application in organic chemistry.—H. S.

*The Quantitative Estimation of Furfuraldehyde and Pentaglucooses.* A. Günther and B. Tollens. Ber. **23**, 1751—1752.

HITHERTO furfuraldehyde has been estimated by precipitation as hydrofurfuramide by means of ammonia. The method sufficed to prove that very little furfuraldehyde is obtained by the distillation of the hexaglucooses and their derivatives with hydrochloric acid or sulphuric acid, and that arabinose and xylose yield about 20—30 per cent. of their weight of furfuraldehyde. The method is, however, far from accurate, and yields very contradictory results.

The authors have succeeded in improving the distillation process with hydrochloric acid so that it yields constant quantities of furfuraldehyde, the latter being estimated volumetrically by means of phenylhydrazine, using aniline acetate as an indicator. The details will be given in a later

paper. For the present the authors content themselves by giving some of the results obtained by the distillation of various sugars with hydrochloric acid. Pure arabinose and xylose yield about 50 per cent. of their weight of furfuraldehyde; cherry gum, 15 per cent.; gum arabic, 14 per cent.; straw from wheat and oats, 13 per cent.; starch and sugar, about  $\frac{1}{4}$ — $\frac{1}{5}$  per cent.; vegetable ivory, 1 per cent.

Assuming that pentaglucooses yield half their weight of furfuraldehyde, it will be seen that cherry gum contains 30 per cent. of these bodies; gum arabic 28 per cent.; and wheat and oat straw, 26 per cent. Glycuronic acid gives 46 per cent. of furfuraldehyde, practically the same as arabinose, whilst only a trace is obtainable from casein.

Finally, the authors mention that the non-crystallisable levo-rotatory sugar which Bieler and Tollens have obtained from the "fecus" by the action of sulphuric acid, is considered by them to be different from all sugars hitherto described, including rhamnose.—H. T. P.

*An Adulteration of Linseed Oil.* A. Aignau. Compt. Rend. **110**, 1273—1275.

A COMMON adulterant of linseed oil is rosin oil. Pure linseed oil being, contrary to the assertions of some writers, destitute of rotatory power, rosin oil may be determined in a mixture with linseed oil by its action on polarised light. The rotation is to the right, and varies somewhat with the kind of rosin oil that has been used. If  $[\alpha]_D$  be called the rotation observed in a 100 mm. tube, and  $h$  the weight of rosin oil contained in the mixture, the value of the latter is given by the formulae:—

$$h = [\alpha]_D \cdot \frac{15}{7} \text{ for refined rosin oil.}$$

$$h = [\alpha] \cdot \frac{30}{17} \text{ for best white rosin oil.}$$

$$h = [\alpha]_D \cdot \frac{30}{21} \text{ for fine rectified rosin oil.}$$

The first is the kind commonly used; a 100 mm. tube is better than one 200 mm. in length on account of the somewhat deep colour usually possessed by the oil.

In the case of a paint, a quantity is shaken up with ether, allowed to settle, and the rotation given by the ethereal solution observed in a 200 mm. tube, the formula used

being  $h = \frac{[\alpha]_D}{43}$ . By evaporating a known quantity of the ethereal solution the total weight of oil can be obtained, and thus the percentage of rosin oil readily calculated.—B. B.

*New Process and Apparatus for Sugar Factories.* Dingl. Polyt. J. **276**, 567—572.

See under XVI., page 877.

#### ERRATUM.

This Journal, 1890, page 823, foot of column 1 and top of column 2, for "J. Ribau" read "J. Ribau," and for "thio-sulphate," "thiosulphates," and "thiosulphuric," read dithionate, dithionates, and dithionie respectively.

## New Books.

**THE RIVER IRWELL AND ITS TRIBUTARIES** (A Monograph on River Pollution). By GEORGE E. DAVIS and ALFRED R. DAVIS, Analytical and Consulting Chemists, Chemical Engineers. Manchester: John Heywood, Deansgate and Ridgefield. London: 1, Paternoster Buildings. 1890.

CROWN 8vo. volume, bound in cloth, price 2s. 6d. A work of 96 pages, with map of the whole of the Irwell watershed. It is the outcome of numerous analyses made in the laboratory of the authors, and it is claimed that though on several occasions isolated analyses have been published of various parts of the river, yet never before has a complete account been given of the watershed. The book is divided into eight chapters, preceded by the map of the watershed, on which is marked the principal towns and the position and name of every contributing stream and brooklet of importance.

Following the "Introduction," which gives an accurate account of the Irwell and tributaries, and an explanation of the principal items of the analyses, we find a chapter devoted to the Irwell at Throstle-Nest Weir, which is further summarised on page 22. Then comes the Irwell up stream as Chapter III., in which we find full analyses of the Medlock, Irk, Roeh, Croal, Tottington Brook, Holecombe Brook, River Ogden, Linney Water, and Whitewell Brook, taken at their points of confluence with the Irwell. The effect of drought is plainly set out in Chapter IV., a chapter full of interest to sanitarians, especially as regards the table on page 44, where the various tributaries at their points of confluence with the Irwell are compared with the Leeds and Salford sewage. The Tributaries in Flood form the subject-matter of Chapter V., while Chapter VI. is devoted to an analysis of the source of each tributary. Pages 66, 67, and 68 contain three tables, setting forth a comparison of the sources of the various tributaries, with their normal flow at point of confluence with the main stream, showing thereby the extent of the pollution which each has suffered during its flow. Chapter VII. deals with the various pollutions, while Chapter VIII. describes with minuteness the methods that have been followed in performing the analyses recorded in the work. It is something for the Manchester local authorities and manufacturers to know that the drought flow of the Irk, Medlock and Tottington Brook is excelled in purity by the Leeds sewage.

**ELECTRO-CHEMICAL ANALYSIS.** By EDGAR F. SMITH, Professor of Analytical Chemistry, University of Pennsylvania. Philadelphia: P. Blakiston, Son, and Co., 1012, Walnut Street. London: H. Grevel and Co., 33, King Street, Covent Garden. 1890.

SMALL 12mo. volume, bound in cloth, and containing Preface, Table of Contents, List of Abbreviations, and subject-matter covering 113 pages, terminating with an alphabetical index. The text is embellished with 25 woodcuts. Price one dollar.

The work is subdivided as follows:—INTRODUCTION. ACTION OF THE ELECTRIC CURRENT UPON ACIDS AND SALTS. OHM, VOLT, AMPÈRE. SOURCES OF ELECTRIC CURRENT:—Grenet battery, Leclanché cell, Daniel cell, Meidinger cell, Crowfoot cell, Bunsen and Grove batteries, Magneto-electric machines, Storage cells, Thermopile. REDUCTION OF THE CURRENT:—Rheostat, Resistance frame. MEASURING CURRENTS:—Voltmeter, Ampèremeter. HISTORICAL SKETCH. SPECIAL PART:—1. Determination of the Metals. 2. Separation of the Metals. 3. Oxidations by means of the Electric Current.

**DR. J. FRICK'S PHYSIKALISCHE TECHNIK.** Specieil Anleitung zur Ausführung Physikalischer Demonstrationen und zur Herstellung von Physikalischen Demonstrations-Apparaten mit möglichst einfachen Mitteln. Sechste umgearbeitete und vermehrte Auflage, von DR. OTTO LEHMANN, Professor der Physik an der technischen Hochschule in Karlsruhe. In zwei Bänden: Erster Band. Braunschweig. Druck und Verlag von Friedrich Vieweg und Sohn. London: H. Grevel & Co., 33, King Street, Covent Garden. 1890.

OCTAVO volume, in paper cover, price 15s., containing Preface, Table of Contents, and Text covering 725 pages. The text is illustrated with 708 excellent engravings. The purpose of the book as stated in the preface is, "In the first place, to serve as a Guide in the carrying out of Experiments in Physics, and to supply details, attention to which will ensure their success, as well as to discuss the construction and treatment of apparatus; and, in the second place, general direction and methods will be given for preparing most of the apparatus in the cheapest and most efficient manner." The work is complete in two volumes, and hence the alphabetical index will only appear in the second volume, yet in the press.

The first part is devoted to the treatment of apparatus in general, and may be regarded as a treatise on the carrying out of some of the more frequently occurring pieces of work in the physical laboratory.

Chap. I.—On the arrangement of the department and treatment of apparatus generally. Chap. II.—The cleaning, repairing, and setting up of apparatus.

The second part is a treatise on individual experiments in physics.

Chap. I.—Experiments on the equilibrium of forces—A. Solid bodies. B. Liquids. C. Gases. Chap. II.—Experiments on heat—A. The change of state of bodies by heat. Chap. III.—Experiments in dynamics and thermo-dynamics—A. The movements of solid bodies. B. The movements of liquids. C. The movements of gases. D. Experiments in conduction of heat.

**Die FARBENREACTIONEN DER KOHLENSTOFFVERBINDUNGEN.** Für Chemische, Physiologische, Mikrochemische, Botanische, Medicinische, und Pharmakologische Untersuchungen, bearbeitet von Dr. EMIL NICKEL. Zweite umgearbeitete, vermehrte und erweiterte Auflage. 1890. Berlin: W. Verlag von Hermann Peters. London: H. Grevel and Co., 33, King Street, Covent Garden.

SMALL 8vo. volume, in paper cover, and a considerable enlargement of the first edition. It contains Prefaces to the first and second editions, Table of Contents, Text covering 121 pages, and an Alphabetical Index of Subject-Matter and Authors. The subject is divided for treatment as follows:—

PART I.—Colour reactions with aromatic substances. Chap. I.—Colour reactions with nitrous acid and its derivatives, with exclusion of azo colour formation. Chap. II.—Colour reactions with nitric acid. Chap. III.—Colour reactions with formation of azo colours. Chap. IV.—Colour reactions with formation of triphenyl-methane colours and analogous compounds. Chap. V.—Colour reactions with the aid of iron salts and chromic acid salts. Chap. VI.—Conclusions derived from PART I.

PART II.—Colour reactions without participation of substances containing the benzene nucleus, and colour reactions of unknown character. Chap. VII.—Colour reactions with members of the cyanogen group. Chap. VIII.—Colour reactions with formation of Mnreoxide and similar colouring matters. Chap. IX.—Colour reactions with formation of colours of inorganic character.

## Trade Report.

### TARIFF CHANGES AND CUSTOMS REGULATIONS.

(From the Board of Trade Journal.)

#### THE NETHERLANDS.

##### Classification of Articles in Customs Tariff.

According to the *Moniteur Belge* for the 17th July, the following decisions affecting the classification of articles in the Netherlands Customs tariff have recently been given by the Customs authorities of that country:—

Carbolic acid and creosote, raw or refined, are taxed as oils not specially distinguished, at the rate of 0.55 fl. per 100 kilos. Products known under the name of carbolinum, guaiacol, ereosol, creoline, and creoline powders are liable to the same duty.

#### UNITED STATES.

##### Recent Customs Decisions.

The following decisions affecting the classification of articles in the Customs tariff, and the application of the Customs law of the United States, have recently been given by the United States Customs authorities:—

A weak solution of peroxide of hydrogen in water not similar to bleaching powder either in material or quality, being similar to such powder only as to some uses to which it may be applied, is dutiable as prescribed by paragraph 92 for chemical compounds not otherwise provided for at the rate of 25 per cent. *ad valorem*.

Certain alizarine gray is dutiable at the rate of 35 per cent. *ad valorem*, under the provision in T.L., 82, for "all coal tar colours or dyes, by whatever name known."

#### CAPE OF GOOD HOPE.

##### Modification of Customs Regulations.

By virtue of section 5 of the Customs Union Tariff Act of 1889, the Governor has directed it to be notified that from and after 8th August last rebate to the extent shown in the schedule below, shall be granted in respect to such articles as are in the said schedule whenever any such articles shall be removed overland to British Bechuanaland and the South African Republic, provided that such articles shall only be removed in accordance with such regulations as the Governor may from time to time prescribe.

#### SCHEDULE.

Articles.	Rebate to be Granted.	Duty less Rebate to be Paid.
Brass in bars, for every 100l. in value .....	£ s. d. 12 0 0	£ s. d. Nil.
Candles, per lb. ....	0 0 1½	0 0 1
Copper, per 100l. in value .....	12 0 0	Nil.
Dynamite, per lb. ....	0 0 2	0 0 1
India-rubber, unmanufactured, per 100l. in value .....	12 0 0	Nil.
Oil, paraffin and linseed, per Imp. gall. ....	0 0 9	0 0 3
Oil, other than preceding (not chemical, essential, or perfumed), for every Imp. gall. ....	0 0 6	0 0 6
Do. (chemical, essential, or perfumed), for every 100l. in value .....	10 0 0	5 0 0
Rosin, for every 100l. in value .....	5 0 0	5 0 0
Salt, per ton of 2,000 lb. ....	0 3 6	0 1 6

#### SCHEDULE—cont.

Articles.	Rebate to be Granted.	Duty less Rebate to be Paid.
Soap, per 100 lb. ....	£ s. d. 0 3 5	£ s. d. 0 0 9
Soda, caustic, for every 100l. in value .....	5 0 0	5 0 0
Turmeric, per 100 lb. ....	1 4 0	0 1 0
Turpentine, per Imp. gall. ....	0 0 10	0 0 2
Varnish, per Imp. gall. ....	0 0 6	0 0 6
Vinegar, per Imp. gall. ....	0 0	0 0 1

#### GOLD COAST.

##### Customs Tariff.

The following is a statement of some of the rates of duty now levied on articles imported into the Gold Coast:—

The undermentioned pay 10 per cent. *ad valorem*:—Kerosene and other illuminating oils, perfumery, soap, sugar, and all other goods not enumerated and unexempted.

The following are admitted free:—Acids, blue indigo, candles, chemicals, drugs and medicines, filters, india rubber, scientific instruments, matches, oils (except kerosene and other illuminating oils), paints, pitch and tar, quicksilver, salts, spirits (methylated, unfit for drinking), and tallow.

### EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

#### EGYPT.

##### Drugs, &c., Imported.

The following gives an idea of the business which is done with Egypt through Alexandria in a few of the staples of our trades:—

Articles.	1889.		1888.	
	Quantity.	Value.	Quantity.	Value.
Olive oil.....	..	£ 105,830	..	£ 83,890
Perfumery and chemical products .....	..	98,082	..	89,722
Soap .....	Lbs. 7,320,992	70,313	6,817,729	72,179
Colours and dyes other than indigo .....	..	61,102	..	43,396
Spices .....	..	56,483	..	44,392

#### Gum Arabic.

The exports of this once-important article are now almost nil, having steadily declined since 1884, when the total exports amounted to 131,000l. Large quantities of gum arabic, ivory, and other valuable products are rotting away in the Soudan, where there is no possibility of exporting or properly storing them.

#### Petroleum.

There was a considerable increase in the imports of petroleum, the total value amounting to 181,291l., against 118,236l. in 1888. The market was, however, overstocked. The use of petroleum has gradually spread throughout Egypt, and has recently been adopted by the Arabs as far south as Wady Halfa, where it was previously almost unknown. Russian oil, on account of its cheapness, has now almost driven American oil out of the market, and, owing to the higher price of the latter, there are instances of the sale of Russian oil as American, the trade-marks being imitated.

## GERMANY.

*Chemicals.*

Our Consul at Frankfurt-on-Main reports that business in chemicals showed a decided improvement in the latter half of 1889. The chemical industry was but little affected by foreign competition, and according to the report of the Chamber of Commerce, some German chemicals have even got the start of English makers, although certain English chemicals still rule the market, and will maintain their position for a long time yet. The trade in pharmaceutical preparations was very satisfactory in the last quarter of the year, the demand having increased, and the profit was fair. In quinine most sales were made by agents, who successfully competed with the manufactories. During the influenza epidemic this article and similar preparations, such as antipyrin, phenacetine, antifebrin, &c., were consumed to such an enormous extent that the manufacturers and dealers were unable to satisfy the demands.

*Cocoa Butter.*

The manufacture of cocoa-butter at Mannheim was less remunerative in 1889 than usual, owing to a deficiency of raw material; nevertheless, the industry may be said to be prospering, having reached a production of 6,000 lb. a day.

## ITALY.

*Lemon Juice.*

The Palermo trade in lemon juice has increased by 5,312*l.*, there having been an augmented demand from France and Great Britain, the two principal markets for this product. France took 4,800*l.*, against 1,186*l.* in 1888. Great Britain raised her demand of 2,115*l.* in 1886, to 3,212*l.* in 1889.

*Sulphur.*

The Consul at Catania reports that the exportation of sulphur underwent a decrease of 9,133 tons as compared with 1888, but the demand became active about the latter part of December for shipment in January and February of the present year. Prices are improving. Sulphur is looked upon as the most important and conspicuous of Sicilian products, and forms the essential resource of the island, being exported to all parts of the world. A new system of fusing, requiring no heavy expenses of plant and no skilled assistance, has lately been introduced by Señor Lion Gil y Ruiz, engineer of the Royal Corps of Engineers in Spain, who first introduced it three years ago in the mines of Buen Viento Corre, belonging to a company in Almeria (Spain), where, after several trials, it obtained a brilliant success. Señor Gil went to Sicily last autumn, seeking a larger field of operation for his invention, and, at his own expense, he planted one of his furnaces on the Mugha mine, where several experiments took place, resulting in a saving of 29 per cent. of sulphur as compared with the old mode of fusing through the Calchione. Referring to "an idea which has found its way that Sicilian sulphur is sooner or later doomed to be excluded from foreign markets," owing to the recovery of sulphur by the "Chance process," the Consul states that Sicilian sulphur, as regards quantities exported, has not suffered from it, and he adds that "Professor Travaglia, of the Mining School of Caltanissetta, a gentleman more than competent in the matter, attaches no importance to the Chance process for obtaining sulphur, and is confident that Sicilian production will still have its markets." Professor Travaglia might change his opinion if he took a summer holiday round about our alkali works in England.

## WOOD-PULP INDUSTRY OF SWEDEN.

Her Majesty's Consul at Stockholm, in his last report on the trade of that capital, says that the manufacture of wood-pulp as a natural product of the country has of late become one of the most important export trades of Sweden. At present there are somewhat more than 120 wood-pulp factories in Sweden, of which about half that number have been started during the last three years.

During 1889 alone 34 new factories have been established. The export from Stockholm compared with the export of last year shows an increase of 6,617 cwt., or about eight times the quantity then exported. The export of the whole of Sweden, which in 1872 only amounted to 114,000 cwt., amounted during 1889 to more than 988,000 cwt. The prices have been constantly declining, but new and improved methods in a like proportion lowered the working cost, and several factories have shown excellent results during latter years. A great number of the factories have been started at places where the iron manufacture has proved a failure. The present improvement in the latter trade, and the heavy increase in the price of charcoal, may, however, cause a decline in the wood-pulp trade.—(No. 772, *Foreign Office Annual Series*.)

## MISCELLANEOUS TRADE NOTICES.

## THE CHEMICAL UNION.

Nearly one hundred of the largest alkali makers were present at the meeting of the alkali trade, called at Liverpool, on Friday, 11th September, at the instance of the promoters of the Chemical Union.

The chairman opened the proceedings by giving a résumé of the labours of the committee from the time of the inception of the scheme to the present. A proof prospectus was handed to each member of the trade present, from which it was gathered that the capital of the Union is to be eight and a half millions sterling, of which seven millions is set against works, plant, land and buildings, and one and a half millions for stocks and working capital.

The capital of the Union will be allotted as follows:—

Two-and-a-half millions in 5 per cent. debentures.

Three millions in 7 per cent. preference shares.

Three millions in ordinary shares.

It is understood that the vendors have agreed to take 70 per cent. of the purchase money in shares, so that it is quite possible that the public may experience a difficulty in obtaining the allotment of any ordinary shares.

The chairman stated that the committee had come to the conclusion to issue the prospectus themselves, without the assistance of any financial intermediary. They were confident of success, and he mentioned that five firms, representing one and a half millions of capital, have stated their intention of taking the *whole* of the purchase money in shares, and it is understood to be the intention of one firm to apply for 100,000*l.* more shares than the amount of their purchase money.—*Chemical Trade Journal*.

## THE ALFA GRASS IN ALGERIA.

According to recent statistics the yearly production of alfa grass is about ten million francs, a sum which could easily be doubled or trebled. But owing to insufficient means of transportation, there are in the Algiers department alone over 15,000 acres of grass running to waste, a loss of 120,000 tons, and as much as 400,000 tons are estimated to be, for the same reason, lost in other parts of the colony. As it is, England purchases nearly four-fifths of the crop, and uses it almost entirely for special qualities of paper. Of the latter paper thus made much is exported to France. The printing paper is especially adapted to fine work and plate-printing. To the use of alfa-grass paper the superiority of English illustrated periodicals is partly to be attributed—if their French competitors are to be believed.—*Chemist and Druggist*.

## MINERAL RESOURCES OF URUGUAY.

The *South American Journal* for the 9th August contains the following information extracted from the *Anuario Estadístico* of the Republic of Uruguay for the year 1888 on the subject of the mineral resources of that State:—

This soil is very rich in minerals, metals, clay, and combustible minerals. Gold, silver, copper, iron, tin, and mercury, are found among the first. Granite, mica, felspar,

various and precious agates, calcareous stone, mountain-rock crystal, marble of different colours, slate, lithographic stones, alum, gypsum, cobalt, calcareous cement, lodestone, marble basalt, and columbite of great value, discovered by Mr. Lettson. A quantity of flints and crystallisations similar to rubies, topaz, zirconite, and emerald, which appear in glittering points in pyramidal shapes, are found in abundance in our mineral kingdom. The mineralogist, Henry Petivenit, found gold, topaz, and diamonds, in the River San Francisco, which runs through Minas, and Mr. Lettson, gold in the departments of Salto and Tacuarembó.

From 1852 up to date, several mines were denounced, and samples of minerals were extracted from Godoy, Barriga Negra, San Francisco de Minas, Arapey, Chico, Aeguaí, and other places.

The working of a lead mine was tried in Soldado, department of Minas, and at present a French company works the gold mines of Cuñapirú in the auriferous region of the department of Tacuarembó. Another company works a copper mine in the department of Maldonado.

In the hills of Arequita, Penitentes, Campanero, Mahoma, and Marincho, since last century the existence of gold has been ascertained.

Gold in veins is found in quartz, and also in nuggets. By the source of the Arapey and Guequay rivers, and especially of the Catalan and Pintado, begins the region of the quartz stone and agates, amethysts, and glittering flints.

Black basalt is plentiful in the hills of Hades and in the vales of Cuareim and Artigas, and on the shores of Invernada. Calcareous stone is also very plentiful, especially in the department of Minas, Maldonado, Florida, and Isla-Mala. Marble is found in the two first departments. It is not rare to find calcareous cement on the left shore of the River Brújás and on the sides of the Cerro of Monte Video; the stones which were employed in the construction of the porticoes of the old city and Cabildo were extracted therefrom. Granite is predominant in these deposits. The felspar in the samples extracted from the hills of San José, in Estanzuela, and near the Aguada, is of pale white or alabastrous, rose or darkish yellow colours. Mica is generally black or dark yellow.

#### THE PETROLEUM DEPOSITS OF PERU.

West from Greenwich 81 deg. 40 min., and south of the equator 3 deg. 40 min., is Zorritos, the centre of the petroleum region of Northern Peru. Lying as it does so near the equator, it would be supposed that the heat would be excessive, but this is not the case, for at a point a little further north commences the rainless region, and as a consequence, the trade winds. These strong breezes are in the morning, from 2 o'clock until 10, from the south-east, and blow strongly, changing at 12 o'clock to south-west. The result is a temperature that does not vary from 70 deg. Fahr. 5 deg. all the year round. The air is perfectly dry, and the climate much recommended for lung diseases.

Abundant surface indications of petroleum exist at and in the vicinity of Zorritos. Some years since a company was formed to develop the district, and they put down some four wells, the largest of which produced 16,000 gallons daily. A refinery was built, and the manufacture of kerosene began. Lack of capital prevented a large development, and it was not until the property came into the hands of the present owner, Mr. Faustino G. Piaggio, that a regular system of work was inaugurated, and it is now one of the best managed properties in South America. There are at present nine wells, and the production is 7,000 cases, or 70,000 gallons, of refined kerosene a month. The specific gravity of the petroleum is 42 deg., producing 22 per cent. of light products, 29 per cent. of illuminating oil, 16 per cent. lubricating, and 33 per cent. of asphalt or brea. The crude petroleum, as well as the distillates, has a sweet aromatic odour, and differs in this respect from many other oils. A very small quantity of acid is used in treating the kerosene, owing to the absence of paraffin, and 2 lb. to 3 lb. of acid is quite sufficient for the purification of 40 gallons of kerosene. The property lies on the shore of the Bay of Zorritos, consisting of 54 pertenencias, or

2,160,000 square metres, having an extension along the coast of 10,800 metres. All of this large tract has surface indications, while the geological formation is all that could be desired, the anticlinal being formed by the shore range of the Andes. The port is smooth and deep, a small railway connects all the offices and shops with the wharf, and the different departments are in communication with the principal office by telephone. No attempt has yet been made to introduce the residuum, after extracting the kerosene, as a combustible for steamers, &c. Good coal is never lower than 15 silver soles a ton, and it has been demonstrated beyond a doubt that three barrels, or 120 gallons, of oil is equivalent to a ton of the best coal. Not only would it seem that the steamers on this coast would use petroleum as a fuel, but the immense saltpetre districts of Arica, Tarapaca, and Antofagasta would be large consumers, once assuring them of a supply. Mr. Piaggio has not been able to extend this branch of the business, as it requires another capital and other direction to carry it through. Attention is being called to Northern Peru, and irrigating companies are being formed. Mines are being developed, and it looks as though a new era had commenced for that country.—*Engineering*.

#### THE PRODUCTION OF QUICKSILVER.

The following statistics of the production of quicksilver in the world have been published by the Statistical Department of the United States, the quantities being in flasks of about 76 lb. each:—

	United States.	Spain, Austria, and Italy.	Total.
1881	60,851	60,082	120,933
1883	46,725	68,394	115,119
1885	32,073	66,281	98,354
1887	33,760	75,027	108,787
1889	26,464	71,772	101,236

From these figures it will be seen that the production of America is diminishing both actually and proportionately, as 10 years ago it was about one-half, whereas now it is little over one-fourth of the whole.—*Industries*.

#### DISCOVERY OF QUICKSILVER.

A fresh rich deposit of quicksilver, at no greater depth than three feet under the surface, has recently been discovered at Mantche, near Wippach, in the Austrian province of Carniola.—*Standard*.

#### EXPORTS OF CHEMICALS FROM THE TYNE.

The following are the exports of chemicals from the Tyne for the month of August and corresponding period of previous year:—

	1890.	1889.
	Tons.	Tons.
Alkali and soda ash.....	1,538	1,102
Bicarbonate of soda.....	6	13
Bleaching powder.....	2,018	1,410
Manure.....	3,612	4,486
Soda crystals.....	990	733
Sulphate of soda.....	64	63
Caustic soda.....	810	2,546
Other chemicals.....	823	
	9,811	10,413

—*Chemical Trade Journal*.

## THE EXPORT OF CAMPHOR FROM JAPAN.

A great impetus was given to the export of camphor from Japan last year by the increase of prices in Europe, and fears were entertained that the supply was being exhausted. Even if this should be the case in some districts, and that it is perhaps so is shown by the fact that the export is being diverted from Nagasaki to Hiogo, new forests of camphor trees appear to become available in others to an extent which prevents any diminution in the aggregate export.—*Industries.*

## THE COTTON-OIL EXPORTS OF THE U.S.A.

The cotton-oil exports of the U.S.A. amounted to 13,384,385 gallons (value 5,291,178 dols.) during the year ending June 30th; that is, five times as much as was exported the year before. In 1875-76 the export was only 281,054 gallons.—*Chemist and Druggist.*

## THE CULTIVATION OF CASTOR OIL IN SENEGAL.

The French *Moniteur Officiel du Commerce* for August 14th publishes a report which the French Colonial Office has received from M. Carstaing, on the subject of the cultivation of the castor-oil plant in Senegal.

In June 1888 M. Carstaing drew the attention of the Governor of the French colony of Senegal to the advantages which would accrue from the cultivation of the indigenous castor-oil plant, particularly the species which spontaneously decorticates itself in the sun, and which M. Carstaing had discovered. The Government agreed to undertake experiments in this direction, and at the end of June 1888, 10,000 seeds were sown in a plantation at Sor, near St. Louis, and 6,500 were distributed to private persons to experiment upon, at the public cost.

The extreme dryness of the climate had prevented the success of several other attempts of a like kind, such as those with arachides nuts, millet, and beans. It was fortunately found that the castor-oil plant was able to resist this obstacle, and in its first season the plantation at Sor produced 300 kilos. of good seeds. In May 1889 other plantations of castor oil were founded at Dakar-Bango, Louga, Kelle, and Thiès. By the close of December 1889 the Government was able to announce that these new areas of cultivation had proved twice as successful as any one had dared to hope. The plants had in six months grown, at Thiès and elsewhere, to a height of from 3 to 4 metres, with a rich crop.

During the rainy season of the present year a great number of applications have been made by planters in various parts of Senegal for seed of the best quality, and fresh plantations have been opened, with 1889 seed, in Rufisque, Gorée, and other places. It has been so clearly shown that the soil and climate of Senegal are favourable to the growth of the castor-oil plant, that preparations are being now made for a very wide cultivation of it throughout the colony in February, March, and April of next year. The principal difficulty in the way of this new industrial enterprise is the resistance of the natives, who cannot be persuaded that arachides nuts and castor oil can be simultaneously grown in the same piece of ground. This is quite a mistake, however; by planting the castor-oil plants of the first year sufficiently sparsely, success is certain.

The principal trading houses of Bordeaux and Marseilles have promised to support the colony of Senegal in the cultivation of castor oil, by offering a market for the product. They consider that the new industry will prove a source of immense wealth to the colony, the present prices being highly remunerative. The accident that the crops of arachides nuts have lately been a failure make the Administration of Senegal only the more anxious to secure this new and valuable product. Offers have already reached Saint Louis from two American houses, and it is believed that the colony will have no difficulty in selling all that it produces.

The numerous uses to which castor oil is now put are very encouraging to the cultivation of the plant. It can be

utilised, besides in its medicinal capacity, in dyeing, soap-making, greasing machinery, lighting, printing, for cement in Java, and for food in China. The Chinese boil it with alum and sugar to remove the bitter taste.

## BOARD OF TRADE RETURNS

## SUMMARY OF IMPORTS.

	Month ended 31st August	
	1889.	1890.
Metals.....	£ 1,718,433	£ 1,863,582

## Monthly Patent List.

\* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—GENERAL PLANT, APPARATUS, AND  
MACHINERY.

## APPLICATIONS.

13,084. C. J. Cario. Improvements in pyrometers. Complete Specification. August 20.

13,127. T. Young. Improvements in valves for corrosive and other fluids. August 21.

13,284. J. Foster. Improvements in and relating to evaporating apparatus. August 23.

13,322. R. Harburn. Evaporating and distilling liquids, which he proposes to call Harburn's patent cyclone evaporator and distiller. August 25.

13,390. J. Batten. Improvements in or relating to regenerating furnaces. August 26.

13,930. H. E. Newton.—From W. J. Maedonagh, R. Rock, W. Wood, C. S. Wilkinson, J. Plummet, and R. B. Wilkinson. An improved appliance for injecting liquid and gaseous fuel into furnaces. Complete Specification. September 4.

14,051. H. Rouart. Improvements in sterilising water and other liquids and apparatus therefor. September 6.

14,059. H. E. Hansen. Improvements in apparatus for the complete evaporation of solutions. Complete Specification. September 6.

14,075. J. A. Orme. Improvements connected with refrigerating apparatus or machinery. September 8.

14,104. H. C. Shaw. Improvements in or relating to furnaces or apparatus for heating boilers, evaporating pans, and other structures. September 8.

14,146. W. Orr and P. S. Brown. Improvements in the construction of lead-lined metallic boxes, tanks, drums, and other vessels. September 9.

14,240. W. L. Wise.—From T. L. Stephanon, Mauritius. Improvements in furnaces. September 10.

- 14,244. W. Barnes and E. M. Clymer. Improved means for feeding coal to furnaces. September 10.  
 14,370. A. Dannenberg. See Class II.  
 14,380. L. Johnstone. See Class IX.

## COMPLETE SPECIFICATIONS ACCEPTED.\*

1889.

- 14,338. C. A. Sahlström and J. C. Bromfield. Furnaces for burning liquid fuel. September 17.  
 14,736. G. F. Redfern.—From W. P. Abell. Centrifugal machines. September 17.  
 16,295. E. Gregory. Apparatus for controlling the cold air supply to furnaces, &c. September 3.  
 16,520. J. Price. Apparatus for distilling and condensing solutions. September 10.  
 16,863. A. H. Hobson. Apparatus for making extracts, and treating soluble substances by steam pressure and heat. September 3.  
 16,997. A. Légé, C. A. Remané, and A. T. Job. Air and vacuum pumps. September 17.  
 17,018. W. K. Bruce. Vacuum pans. August 27.  
 18,324. W. W. Bengough. Apparatus for heating, evaporating, and condensing. September 10.  
 18,528. H. H. Lake.—From La Société Anonyme des Parfums Naturels de Cannes. Method and apparatus for the lixiviation of various materials. September 17.

1890.

8544. W. H. Johnson and C. C. Hutchinson. Filter presses. September 3.  
 10,172. H. von Bayer. Method and apparatus for producing cold. August 27.  
 11,246. J. Klein. Process and apparatus for cooling liquids by means of air. September 10.

## H.—FUEL, GAS, AND LIGHT.

## APPLICATIONS.

- 13,033. F. Lennard and E. W. Harding. Improvements in the manufacture and production of artificial fuel. Complete Specification. August 19.  
 13,332. H. Stevenson. An improved method of and apparatus for heating. August 25.  
 13,355. H. Macaulay. Improvements in means or apparatus for regulating the heat and combustion of fuel. August 25.  
 13,364. W. Fenton and W. Graham. An improved manufactured fuel. August 25.  
 13,382. W. Welch. Improvements in purifying coal and water-gas and other inflammable vapours, and apparatus therefor. August 26.  
 13,398. W. H. Nevill. Improvements in the treatment of coal tar and pitch. August 26.  
 13,477. M. Fromont. Improvements in the production of coke, and in apparatus employed therefor. August 27.  
 13,499. F. J. Jones. Improvements in the manufacture of coke, and in purifiers for use therein, and in the manufacture of gas. August 27.

13,574. B. H. Thwaite. Improvements in methods of producing combustible gases for heat and lighting purposes, and in apparatus therefor. Complete Specification. August 29.

13,767. J. Gridley. Improvements in and relating to the treatment of wood, rendering the same highly inflammable. Complete Specification. September 2.

13,962. F. S. Craig and W. J. Cowden. Improved patent fuel. September 5.

14,052. L. H. Armour. Improvements in means employed in the manufacture of hard coke, the distilling of shale, the washing of ores or other operations wherein carbonaceous matter is subjected to the action of heat. September 6.

14,109. J. A. Rossiter. Improved means for generating heat. September 8.

14,112. S. A. Johnson. Improvements in effecting the combustion of fuel, and prevention of smoke in steam boilers, also applicable for domestic fire-grates. September 8.

14,115. H. H. Lake.—From J. Lundström and Co., Sweden. Improvements in the manufacture of artificial fuel. September 8.

14,122. E. P. Jarrard. Improvements in or pertaining to lighting. September 9.

14,297. G. Webb. Improvements in carburettors. September 11.

14,298. G. Webb. A new or improved process and apparatus for supplying gas lighting in a portable form to railway, omnibus, and other vehicles, and for other purposes. September 11.

14,370. A. Dannenberg. Improvement in the methods of firing of periodically and continuously worked chamber and annular furnaces. Complete Specification. September 11.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

12,054. B. H. Thwaite. Method of distributing, heating, and lighting gas. September 3.

14,060. F. N. Mackay. Method and apparatus for separating tar and ammonia from gases. September 10.

17,140. A. A. Fritz. Apparatus for producing an inflammable gas by carburization of air. September 3.

17,232. N. M. Henderson. Apparatus for distilling mineral oils. September 10.

17,467. E. Lund. Improvements in night-lights and holders for same. September 17.

17,673. The Coltness Iron Co., Lim., and W. Young. See Class X.

17,778. H. H. Lake.—From G. W. Wilcox. Apparatus for preventing smoke and economising fuel. August 27.

19,572. W. Wood. Apparatus for the manufacture of illuminating or heating gases. September 17.

1890.

2341. F. Scudder and H. G. Colman. Manufacture or treatment of gases containing carbonic oxide to render them odorous. September 3.

7040. J. J. Cooper. Improvements in carburettors. September 17.

### III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

#### APPLICATIONS.

13,398. W. H. Nevill. *See Class II.*

### IV.—COLOURING MATTERS AND DYES.

#### APPLICATIONS.

12,962. B. Willeox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. Improvements in the manufacture and production of nitroso combinations, and of colouring matters therefrom. August 18.

13,010. W. Majert. Improvements in the manufacture of colouring matters. August 19.

13,165. J. R. Geigy. Production of mono and disulpho acids of tetramethyldiamidodiphenylmethane. August 21.

13,235. B. Willeox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. Improvements in the manufacture and production of azo dyes. August 22.

13,443. B. Willeox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture and production of new sulpho-acids of dioxy-naphthaline or amidonaphthol and of azo colouring matters therefrom. August 26.

13,516. R. Holliday and Sons, Limited, and T. Holliday. The production of a new sulpho acid of naphthylamine. August 28.

13,565. H. H. Lake.—From Wirth and Co., agents of A. Leonhardt and Co., Germany. Improvements in the manufacture of colouring matters. August 28.

13,627. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik, Germany. The manufacture and production of a new indigo blue and sulpho acids thereof. August 29.

13,710. J. Dawson and R. Hirsch. A process for the production of substituted benzidines (diamidotriphenyls) and colours therefrom. September 1.

14,416. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik, Germany. The manufacture and production of new amido-azo compounds and azo dyes therefrom. September 12.

14,432. J. Dawson and R. Hirsch. A process for the production of a substantive cotton colour. September 13.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

15,450. B. Nicholson and T. Palmer. *See Class XIV.*

17,024. O. Imray.—From The Farbwerke Griesheim-on-Main, W. Noetzel and Co. Manufacture of indulin-like colouring matters. September 17.

17,223. H. H. Lake.—From Wirth and Co., agents for A. Leonhardt and Co. Manufacture of colouring matter. September 3.

17,957. O. Imray.—From The Actiengesellschaft für Anilin Fabrikation. Preparation of orange-yellow colouring matters. September 17.

17,971. H. H. Lake.—From A. Leonhardt and Co. Improvements relating to colouring matters. August 27.

1890.

8541. J. J. Hart. Development or treatment of colouring matters in textile fabrics. September 3.

### V.—TEXTILES, COTTON, WOOL, SILK, Etc.

#### APPLICATIONS.

13,701. H. H. Lake.—From Eesales and Hatry, Germany. Improvements in and relating to the weaving of silk waste. August 30.

13,756. A. H. Norman. A cheap method of obtaining fibres from rami, esparto, or similar grasses. September 2.

13,965. K. T. Sutherland and G. Esdaile. Improved treatment of long-staple stalk-fibres, as China-grass, flax, and such like fibres, by which they will have a more even staple when artificially shortened. September 5.

13,997. S. Pitt.—From L. Vignon, France, and L. Cassella and Co., Germany. Improvements in animalising cotton and other vegetable fibres. September 5.

14,246. D. Gantillon. A method or process of treating silk or mixed silk fabrics to give them the appearance of China crepe. September 10.

14,389. A. Watson. An improved process whereby lace curtains and similar articles are treated. September 12.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

16,708. C. Baswitz. Treating textiles by ammoniac copper to make them waterproof and nonflammable. August 27.

1890.

12,689. K. Trobach and G. J. Bruch. *See Class VI.*

### VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

#### APPLICATIONS.

12,907. E. Sykes, D. Sykes, E. Heppenstall, T. Greenwood, and J. W. Whiteley. Improvements in machinery for scouring, dyeing, and drying hanks of yarn, slivers of fibre, and slubbings. August 18.

12,950. H. Thies and E. Herzog. Improvements in bleaching. Complete Specification. August 18.

13,048. S. Pitt.—From A. Smith and Sons' Carpet Co., United States. Certain new and useful improvements in dyeing apparatus. Complete Specification. August 19.

13,184. I. F. Peck. Improvements in apparatus for dyeing yarn. August 21.

13,861. G. Jagenburg. Improved means and apparatus connected with washing, mordanting, or dyeing spun and unspun textile fibres. September 3.

13,963. J. H. Gartside and W. Warr. Improvements in dyeing wool, cotton, silk, or jute, or other fibre, or a mixture of wool and cotton black. September 5.

14,302. T. Ingham. Improvements in dyeing cotton. September 11.

14,372. J. Robertshaw. Improvements in dyeing, sizing, and washing machines. September 12.

14,399. E. T. Aucher. A process for dyeing raw cotton aniline black. September 12.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

19,490. L. Schreiner. Dyeing aniline black. August 27.

1890.

8541. J. J. Hart. See Class IV.

11,873. H. H. Lake. — From The L. Weldon Dyeing Machine Co. Yarn-dyeing machines. September 3.

12,689. K. Trobach and G. J. Bruch. Obtaining and bleaching vegetable fibres. September 17.

## VII.—ACIDS, ALKALIS, AND SALTS.

## APPLICATIONS.

13,240. L. M. C. Folie-Desjardins. Process and apparatus for the simultaneous manufacture of phosphorus and of alkaline silicates by the treatment of the mineral phosphates of lime, alumina, or bone ash. August 22.

13,312. F. Ellershausen. Improvements in the manufacture of sulphide of sodium. August 23.

13,373. F. Ellershausen. Improvements in the manufacture of caustic soda. August 25.

13,504. T. J. Hutchinson. Improvements in the method of obtaining useful products from bleaching powder dregs, and lime mud from paper works. August 28.

13,863. B. E. R. Newlands. Improvements in the treatment of phosphoric acid for facilitating its storage and transport. September 3.

13,871. J. E. Bennett. Improvements in furnaces and flues for evaporation pans used in the manufacture of salt. September 4.

13,929. F. Ellershausen. Improvements in the production of sulphite and hyposulphite of soda. September 4.

14,022. C. Négrier. Improvements in furnaces for concentrating sulphuric acid. Complete Specification. Filed September 6. Date applied for April 26, 1890, being date of application in France.

14,084. E. Meyer. Improvements in the manufacture of hydrate of alumina from silicates of alumina or clay. September 8.

14,483. T. Raynaud. Improvements relating to the production of soda and chlorine. September 13.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

17,074. T. Turner. Treatment of waste pickle from galvanising works, and other such acid liquors, and apparatus therefor. August 27.

17,395. W. Garroway. Obtaining caustic soda or potash by means of boracic acid. September 3.

1890.

11,699. G. Nahnsen. See Class XI.

12,641. C. T. J. Vautin. Producing chlorine gas for the chlorination of gold or other ores. September 17.

## VIII.—GLASS, POTTERY, AND EARTHENWARE.

## APPLICATIONS.

13,134. C. D. Abel. — From the firm of J. Meurin, Germany. An improved manufacture of bricks, slabs, pipes, pipe stones, and other similar articles. August 21.

13,155. L. H. Jahn. Improvements in or connected with the firing of pottery. August 21.

13,222. S. Sambrook. Improvements in enamelling, hardening on, and fret kilns used by earthenware and china manufacturers; also partly applicable in the construction of bakers' and confectioners' ovens. Complete Specification. August 22.

13,282. J. Kirkman. Improvements in the construction of kilns or ovens for burning or baking pottery bricks, tiles, and the like. August 23.

13,331. J. Hamblet. Improvements in and apparatus for the manufacture of ornamental flooring tiles, and other tiles. August 25.

13,374. J. J. Barclay and J. Meikle. Improvements in kilns and apparatus for drying and burning bricks, pottery, &amp;c. Complete Specification. August 25.

13,436. F. C. Roberts. Improvements in pottery kilns. Complete Specification. August 26.

13,707. J. Gill. An improved method for the making of roofing tiles and flooring tiles. September 1.

14,211. D. Rylands and H. F. Boughton. Improvements in the manufacture of glass, and in furnaces for the melting thereof. September 10.

14,328. H. Bonnycastle and T. M. Rymer-Jones. An improvement in the manufacture of refractory and non-conducting bricks, blocks, tiles, slabs, and pipes. September 11.

14,359. L. Fargue. Improvements in the manufacture of stained or ceramic transparent glass windows. September 11.

14,360. C. O. Weber and G. F. Freeman. Improvements in the manufacture of artificial stones for lithographie and similar printing purposes. September 11.

14,383. C. E. Hawley. Improvements in the manufacture of chamber and other ware. September 12.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

16,326. E. Smith. Apparatus for making earthenware socket pipes. September 3.

16,475. W. B. Fitch. Manufacture of metal-coated glass and porcelain ware. August 27.

16,843. A. Drummond. Apparatus for rolling out glass sheets with surface designs. September 3.

17,565. J. G. Sowerby. Manufacture of antique and other sheet glass, and apparatus therefor. September 10.

1890.

11,560. A. Schaaf. Drying stoves for ceramic materials. September 3.

## IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

### APPLICATIONS.

13,105. A. McLean. An improved decorative artificial stone. August 20.

13,216. J. Grainger. A new concrete ventilated building block for building purposes. August 22.

13,227. C. R. Bonné.—From M. Henry, France. Improvements in the manufacture of cement, such as Portland or slag cement. August 22.

13,331. W. S. Lea, J. C. Darby, and R. M. G. Dill. An improved cement or cements, specially suitable for resisting acids, alkalis, combinations thereof, and the manufacture of the same. August 25.

13,384. J. Juogblutb. Improved composition or concrete flooring for stables, public baths, slaughter-houses, and the like. Complete Specification. August 26.

13,595. H. P. Williams and E. G. Williams, trading as Pilkington and Co. An improved artificial asphalt. August 29.

13,620. J. Brown, J. W. Virgo, and H. F. Ainly. An improved composition to be used in the mixing of mortars, cements, and plasters, for building and other purposes. August 29.

14,380. L. Johnstone. Improvements in or connected with rotative furnaces or kilns for treating and recovering waste gases from raw or partially raw materials, used more especially and for example in the manufacture of cement. September 12.

14,398. C. von Forell. A process for manufacturing from Roman cement a composition similar to Portland cement. September 12.

14,439. J. Clemenson and T. Clemenson. An improved method or process of manufacturing Portland cement, and improvements in apparatus employed therein. September 13.

### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

15,406. W. J. Oswald, J. R. Ashwell, and J. A. Cooke. Manufacture of plaster of Paris, and utilisation of waste materials therefor. September 3.

17,758. H. A. Bassett. Manufacture of building material and of a composition for use therewith. September 17.

1890.

6711. F. C. Goodall. Marine cement. September 3.

8606. S. G. T. C. Bryan. Treating slag for manufacture of building blocks, paving blocks, &c. September 17.

10,002. T. Breakell and J. W. Breakell. Colouring and polishing calcareous and other stones, and producing variegated effects thereon. September 10.

## X.—METALLURGY, MINING, ETC.

### APPLICATIONS.

12,912. G. Rodger. Improvements in or connected with apparatus for making steel. August 18.

12,938. S. O. Cowper-Coles. Improvements in coating wires with the heavy metals and alloys of the same. August 18.

13,137. G. W. Clark, J. Clark, and W. G. Dickson. Improvements in obtaining aluminium chloride, and obtaining aluminium therefrom. August 21.

13,174. J. H. Lancaster and M. R. Conley. An improved process for the manufacture of steel, and apparatus therefor. August 21.

13,259. C. T. J. Vautin. Improvements in apparatus for the extraction of gold. Complete Specification. August 22.

13,356. H. Y. Castner. Improvements in the manufacture of sodium and potassium. August 25.

13,393. S. O. Cowper-Coles. Improvements in the deposition of alloys. August 26.

13,413. T. Held. A process for obtaining a new metallic alloy. August 26.

13,474. W. L. Wise.—From L. Benchemans, Belgium. Improved process for roasting ores and metallic compounds. August 27.

13,486. A. Schneller and A. Astfalie. Improved process for the production of pure aluminium. August 27.

13,723. F. H. Molesworth. Improvements in the process of treating metalliferous ores. Complete Specification. September 1.

13,811. J. J. Knight and J. W. Bottomley. Improvements in the treatment of substances containing phosphorus and aluminium. September 3.

13,856. F. Burger and R. Mannheimer. A new product or compound for preventing the formation of pores in molten metals, and the manufacture of the same. September 3.

14,053. F. A. Herbertz. Improvements in smelting furnaces. Complete Specification. September 6.

14,063. H. H. Lake.—From C. F. Claus, Germany. Improvements in and relating to the annealing of wire, sheet metal, and other metal articles. September 6.

14,445. C. While. Melting and mixing iron. September 13.

### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

13,301. W. Deighton. Improvements in steel-making and other "water-gas" furnaces. 27 August.

14,462. A. J. Campion and J. E. Tenison-Woods. Treating tinned or galvanised scrap iron. September 10.

14,880. W. R. Lake.—From E. Thomson. Welding, shaping, and otherwise working metals. September 3.

15,970. W. C. Taylor and T. N. Kirkham. Treating gold quartz and other minerals to facilitate their reduction to powder. September 10.

16,318. H. Marbeau. Manufacture of alloys of nickel with other metals. August 27.

16,338. F. E. Ross. Improvements in cupola and blast furnaces. August 27.

16,868. E. A. Cowper. Recovering float gold. September 10.

17,673. The Coltness Iron Co., Limited, and W. Young. Treating gases from blast furnaces, gas producers, and coke ovens, and apparatus therefor. September 10.

18,062. H. Y. Castner. Purifying the anhydrous double chloride compounds of aluminium. September 17.

19,588. C. A. Faure. Manufacture of ferro-aluminium. September 10.

20,395. T. Brady, T. C. Powers, M. J. Quinn, and A. J. Maher. Apparatus for casting ingots. September 17.

1890.

8606. S. G. T. C. Bryan. See Class IX.

8992. H. W. Lash and J. Johnson. Reduction of ores. August 27.

12,641. C. T. J. Vautin. See Class VII.

## XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

### APPLICATIONS.

13,003. D. Pepper, jun. Improvements in the manufacture of electrodes for primary and secondary batteries. Complete Specification. August 19.

13,006. H. H. Lake.—From E. Thomson, United States. Improvements in welding or otherwise working metals by electricity, and in apparatus therefor. Complete Specification. August 19.

13,013. D. Pepper, jun. Improvements in the manufacture of electrodes for primary and secondary batteries. Complete Specification. August 19.

13,024. G. O. Rennerfelt. Method of and apparatus for producing, by means of electrolysis, decomposed products of melted haloid salts and other combinations of metals. Complete Specification. August 19.

13,261. W. J. S. Barber-Starkey. Improvements in and connected with primary galvanic batteries. August 23.

13,344. H. J. Allison.—From P. Hathaway, United States. Improvements in galvanic batteries. Complete Specification. August 25.

13,421. W. P. Thompson.—From C. L. Coffin, United States. Improvements in apparatus for working or welding metals electrically, and in the method of effecting the same. August 26.

13,463. J. Mosely. Improvements in and connected with zincs for galvanic batteries. August 27.

13,557. T. S. E. Dixon. Improvements in secondary batteries. Complete Specification. Filed August 28. Date applied for, February 6, 1890, being date of application in United States.

13,635. W. P. Thompson.—From C. L. Coffin, United States. Improvements in or appertaining to electric welding. Complete Specification. August 30.

13,636. W. P. Thompson.—From C. L. Coffin, United States. Improvements in electric welding. Complete Specification. August 30.

13,735. C. Hocpfner. Improvements in apparatus for use in electro-metallurgical operations. September 1.

13,807. C. M. Reed. An improved battery compound. Complete Specification. September 2.

13,853. C. A. Faure. Improvements in the production of electricity, and in means or apparatus therefor. September 3.

13,905. M. W. Dewey. Improvements in and relating to the welding of metals by electricity. Complete Specification. September 4.

13,906. M. W. Dewey. Improvements in and relating to the welding and brazing of metals by electricity. Complete Specification. September 4.

14,411. J. T. Niblett. Improvements in secondary batteries. September 12.

### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

11,962. P. Naef. Manufacture of peroxide of lead and by-products. September 3.

15,700. W. B. Sayers. Dynamo machines for electroplating. September 3.

1890.

8086. M. Bailey and J. Warnes. Secondary batteries. September 3.

10,123. M. W. Dewey. Welding, soldering, and otherwise working metals by electricity. September 10.

10,124. M. W. Dewey. Electric heating apparatus. September 10.

11,533. M. G. Farmer. Electrolytic apparatus for forming copper ingots. September 10.

11,680. M. G. Farmer. Apparatus for producing sheets of metal by electro-deposition. September 3.

11,699. G. Nahusen. Obtaining chlorine and bromine by aid of electricity. September 17.

## XII.—FATS, OILS, AND SOAP MANUFACTURE.

### APPLICATIONS.

13,634. C. A. Feuerlein and J. C. Lahusen. Improvements in or appertaining to the production of odourless wool grease. August 30.

13,803. C. A. Jensen.—From P. Moller, Germany. Improvements in the manufacture of cod-liver oil. Complete Specification. September 2.

13,891. D. Rossi. An improved paste or soap for removing grease. September 4.

13,981. G. P. Clarke.—From D. R. S. Galbraith and T. Bell, New Zealand. Improvements in the preparation of soap. September 5.

13,985. G. P. Clarke.—From D. R. S. Galbraith and T. Bell, New Zealand. Improvements in soap powders. Complete Specification. September 5.

14,239. J. Pettigrew. A new composition for cleaning painted or varnished work. September 10.

### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

14,364. E. Mansfield. Method and apparatus for extracting oleaginous and other matters from fibrous spun textiles, &c. September 10.

17,163. W. Brinck. Lubricants. September 3.

18,628. L. T. Thorne and Brin's Oxygen Co., Lim. Oxidation and thickening of oils for use in the manufacture of paints, varnishes, &c. September 10.

## XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

### APPLICATIONS.

13,294. A. F. Bilderbeek-Gomess. Improved process of devulcanising vulcanised india-rubber, gutta-percha, and similar gums, and reclaiming the rubber therefrom for manufacture without the addition of pure rubber. August 23.

13,719. E. Schmal. Medium for using earth and chemical colours. Complete Specification. September 1.

13,769. A. C. A. Holzapfel. An improved composition for preventing corrosion and fouling on ships' bottoms and other submerged surfaces. September 2.

13,861. A. A. Blandy. Improvements in the combination and treatment of certain materials for the production of substances as a substitute for india-rubber and leather, and for other substances and purposes for which it may be applicable. September 3.

14,106. H. Joyce. Improvements in polishes or compositions for leather and other surfaces. September 8.

14,107. R. F. Metzeler. An improved vulcanised composition. September 8.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

14,150. S. Kenyon. Treating india-rubber to render it soluble. September 10.

15,805. W. L. Wise.—From J. P. Perkins. A new pigment or paint base, and method of producing same. August 27.

18,628. L. T. Thorne and Brin's Oxygen Co., Limited. See Class XII.

#### XIV.—TANNING, LEATHER, GLUE, AND SIZE.

##### APPLICATIONS.

13,603. D. Cielitira. An improved method for the instantaneous production of imitation Russia leather. August 29.

13,794. E. Edwards.—From A. Nicolet, France. Improvements in the preparation and treatment of skins and leather. September 2.

13,796. W. J. J. Hawkins. Improvements in printers' roller composition. September 2.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

15,450. B. Nicholson and T. Palmer. Preserving and recovering the colouring matters from tanning and other vegetable extracts. September 10.

16,595. H. Bogenschield and F. Busch. Process and apparatus for glazing leather. September 17.

#### XV.—AGRICULTURE AND MANURES.

##### APPLICATION.

14,321. A. Buchanan. — From A. W. Tait, Portugal. Improvements in compounds for protecting vines, potatoes, and other vegetable growths from disease. September 11.

#### XVI.—SUGARS, STARCHES, GUMS, Etc.

##### APPLICATION.

13,444. J. Y. Johnson.—From A. L. L. Peek, United States. Improvements in the manufacture of lactose or milk sugar. August 26.

#### XVII.—BREWING, WINES, SPIRITS, Etc.

##### APPLICATIONS.

12,932. W. T. Thorp. An improved beer compound. August 18.

13,257. G. F. Redfern.—From G. Perschied, United States. Improvements in the manufacture of wine, and in apparatus therefor. Complete Specification. August 22.

13,428. H. H. Lake.—From The Handford-Stanford Co., United States. Improvements in apparatus for cooling and aerating wort in the manufacture of malt liquors. Complete Specification. August 26.

13,608. R. Genge. Improvements relating to the production of dry yeast, cattle food, and spirit from maize, wort, and refuse spirit liquors. August 29.

13,694. M. Konig. Improvements in malt curing apparatus. Complete Specification. August 30.

13,862. B. E. R. Newlands. Improvements in the treatment of grain and malt, and the production therefrom of a new product more especially intended for use in brewing and distilling or as a food. September 3.

14,118. G. Roskilly. Refining and heading malt liquors. September 8.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

15,568. J. F. Gallogly. Maturing and mellowing new whisky, brandy, or like alcoholic liquors. September 10.

16,556. D. Wickham. Novel condensing cylinder for gasating malt and other liquors. August 27.

1890.

6337. W. Paterson. Preventing and arresting development of acids during malting or storage of barley and other cereals, and in the infusion of malted barley for the manufacture of concentrated malt extract, or for all brewing purposes. September 3.

10,845. A. Boake and F. G. A. Roberts. Means of applying certain antiseptics to beer, wine, &c. September 17.

11,249. A. Regel. Pasteurising apparatus. September 16.

11,554. G. F. Redfern.—From J. F. Gronwald, E. H. C. Oehlmann, and G. H. Neuhauss. See Class XVIII.—A.

#### XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

##### APPLICATIONS.

##### A.—Chemistry of Foods.

12,955. G. H. Hamrick. The manufacture and preservation of butter. Complete Specification. August 18.

13,067. J. G. Lorrain.—From F. J. Chevet, France. A new or improved alimentary preparation, and method of manufacturing the same. August 20.

13,068. J. G. Lorrain.—From F. J. Chevet, France. A new or improved alimentary preparation, and method of manufacturing the same. August 20.

13,069. J. G. Lorrain.—From F. J. Chevet, France. A new or improved alimentary preparation, and method of manufacturing the same. August 20.

13,070. J. G. Lorrain.—From F. J. Chevet, France. A new or improved alimentary preparation, and method of manufacturing the same. August 20.

13,089. C. L. Bachelier. A new or improved process and apparatus for preserving organic substances, and especially alimentary substances. Complete Specification. August 20.

13,140. W. H. E. Rawlings. A new digestive milk food. August 26.

13,552. W. F. Scutt. Solid milk. August 28.

13,792. A. H. Cone. A baking powder. September 2.

13,824. F. W. Waide. Improvements in mixing and preserving meats, fish, game, and the like, with apparatus for performing the same. September 3.

14,051. H. Rouart. See Class I.

#### *B.—Sanitary Chemistry.*

12,910. A. C. Wilson and A. Ford. Improvements in and relating to the treatment of town, ashpit, or the like refuse, and in the means or apparatus employed therefor. August 18.

14,142. G. V. Alsing. Improvements in the utilisation of sewage sludge for the purpose of vitrification. September 9.

14,253. A. O. Jones and S. Fox. Improvements in the treatment of sewage. September 10.

14,254. A. O. Jones. Improvements in the treatment of sewage, and apparatus therefor. September 10.

#### *C.—Disinfectants.*

13,046. W. P. Thompson.—From J. R. Bate, F. W. Owen, and J. W. Simcock, United States. Improvements in and relating to preserving compounds for embalming purposes. Complete Specification. August 19.

13,488. J. Y. Johnson.—From E. Salomon, France. The manufacture and production of a new antiseptic. Complete Specification. August 27.

#### COMPLETE SPECIFICATIONS ACCEPTED.

##### *A.—Chemistry of Foods.*

1890.

10,950. M. Persson. Preparation of condensed cream. September 3.

11,554. G. F. Redfern.—From J. F. H. Gronwald, E. H. C. Oehlmann, and G. H. Nenhaus. Apparatus for sterilising milk and other liquids, and decanting same. August 27.

11,586. Y. Tobias and H. Fischer. A liquid chocolate, free from fat and preservable. September 3.

##### *B.—Sanitary Chemistry.*

1889.

17,898. A. Young. Apparatus for destroying noxious vapours of drains, sewers, hospitals, &c. September 17.

1890.

4732. W. Birch. Apparatus for filtering sewage, &c. September 10.

#### *C.—Disinfectants.*

1890.

12,323. H. H. Lake.—From W. F. Simes. Compound for disinfecting and other purposes. September 10.

#### XIX.—PAPER, PASTEBOARD, ETC.

##### APPLICATIONS.

13,677. A. Johnstone. Improvements in the manufacture of paper and in mechanism connected therewith. August 30.

#### XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

##### APPLICATIONS.

12,993. J. Y. Johnson.—From F. von Heyden, Germany. Improvements in the manufacture of oxyphthalic acids (phenol dicarbonic acids). August 19.

14,437. M. Freund and M. Heim. Process of producing new derivatives of hydrastine and narcotine. September 13.

#### COMPLETE SPECIFICATION ACCEPTED.

1889.

16,555. O. Imray.—From W. MacKean. Obtaining salts of thorium, zirconium, and like metals, from their ores or from waste residues of hoods used for incandescent gas lighting. August 27.

#### XXI.—PHOTOGRAPHIC PROCESSES AND MATERIALS.

##### APPLICATIONS.

13,262. J. C. Osborne. The removal of the action of light on untuned sensitised and albuminised photographic papers and surfaces. August 23.

13,836. J. J. Aeworth. Improvements in the manufacture of photographic films and in apparatus therefor. September 3.

13,937. C. Ball, P. N. Evans, and Q. Wirtz. Method of rendering photographs on glass, china, or the like, permanent. September 4.

14,189. V. Planchon. Improvements relating to films for use in photography. September 9.

## XXII.—EXPLOSIVES, MATCHES, Etc.

## APPLICATIONS.

13,085. M. Meisgen and M. Hett. An improved fuse or priming machine for kindling fuels. Complete Specification. August 20.

13,801. G. W. Thomas. Improvements in matches, fuses, and the like. September 2.

14,080. C. O. Lundholm, J. Sayers, and W. Cullen. Improvements in the manufacture of explosives. September 8.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

11,678. A. V. Newton.—From A. Nobel. Improvements in cartridges. September 10.

16,028. P. Molyneux. Improvements in wax matches. August 27.

16,426. J. S. Taylor and S. W. Challen. Plant for burning special charcoal for the manufacture of gunpowder. September 10.

1890.

9315. E. N. Todd. Manufacturing thin sheets of nitro-cellulose. September 10.

11,018. W. P. Thompson.—From S. D. Smolianinoff. Explosive compounds. September 10.

# THE JOURNAL

OF THE

# Society of Chemical Industry:

## A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 10.—VOL. IX.]

OCTOBER 31, 1890.

[Non-Members 30/- per annum; Members 21/- per Set of extra or back numbers; Single Copies (Members only) 2/6.]

## The Society of Chemical Industry.

### Past Presidents:

Sir H. E. Roscoe, M.P., LL.D., V.P.R.S. ....	1881—1882.
Sir Frederick Abel, C.B., D.C.L., F.R.S. ....	1882—1883.
Walter Weldon, F.R.S. ....	1883—1884.
W. H. Perkin, Ph.D., F.R.S. ....	1884—1885.
E. K. Muspratt ....	1885—1886.
David Howard ....	1886—1887.
Prof. James Dewar, F.R.S. ....	1887—1888.
Ludwig Mond ....	1888—1889.
Sir Lowthian Bell, Bart., F.R.S. ....	1889—1890.

## COUNCIL FOR YEAR ENDING JULY, 1891.

*President:* E. Rider Cook.

### Vice-Presidents:

Sir Lowthian Bell, Bart., F.R.S.	Ludwig Mond.
R. Forbes Carpenter.	Dr. Hugo Muller, F.R.S.
Prof. James Dewar, F.R.S.	B. E. R. Newlands.
James Duncan.	Dr. W. H. Perkin, F.R.S.
David Howard.	Dr. Edw. Schunck, F.R.S.
S. H. Johnson.	J. C. Stevenson, M.P.

### Ordinary Members of Council:

A. H. Allen.	Prof. R. Meldola, F.R.S.
J. Archbutt.	E. K. Muspratt.
S. B. Boulton.	T. L. Patterson.
Jno. Brock.	Jno. Pattinson.
Jno. Calderwood.	Jno. Spiller.
H. Grimshaw.	T. W. Stuart.

With the Chairmen and Secretaries of Sections.

### Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

### Honorary Foreign Secretary:

Dr. Ferdinand Hurter.

*General Secretary:* Charles G. Cresswell.

### Offices:

Palace Chambers, 9, Bridge Street, Westminster, S.W.

## NOTICES.

Foreign and Colonial Members are hereby advised that the subscription of 25s. for 1891, payable on January 1st next, should be sent in good time to the Treasurer in order to ensure continuity in the receipt of the Society's Journal. Any changes of address which it is desired should appear in the new List of Members should reach the General Secretary not later than January 15th, 1891.

Post Office Orders should be made payable at the General Post Office, London, to the Honorary Treasurer, E. Rider Cook, and should be forwarded to him at Bow, unless it be desired to notify a change of address.

Members who require extra sets or back numbers of the Journal are requested to make application to the General Secretary only, to whom also changes of address should be communicated.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 11 of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed.

The Secretary is instructed to negotiate for the purchase of copies of the Society's Journal for January 1883, and January, February, and April 1886. Members possessing odd copies of these numbers are particularly requested to communicate at once, stating price required, with Mr. Cresswell. The stock of all other numbers is at present sufficient for the Council's requirements.

#### LIST OF MEMBERS ELECTED, 23rd OCTOBER, 1890.

Ashton-Bost, W. D., Cartvale Chemical Works, Paisley, N.B., chemical manufacturer.

Birch, Wm., Milton Street Ironworks, Lower Broughton, Manchester, machinist.

Bruce, Jas., Cluan House, Mountpottinger, Belfast, distiller.

Butler, Paul, Lowell, Mass., U.S.A., ammunition manufacturer.

Criper, W. R., Chemical Works, Cossipore, Calcutta, India, manufacturing chemist.

Crissey, W. G., c/o Seabury and Johnson, East Orange, N.J., U.S.A., manufacturing chemist.

De Velling, F. W., Upper Board School, Heckmondwike, Yorks, schoolmaster.

Gajjar, Professor T. K., Temple of Art, Baroda, India, principal, and professor of chemistry.

Garrett, F. C., 2, Westoe Terrace, South Shields, science master.

Glendinning, Tom A., The Brewery, Leeds, chemist.

Harned, Frank P., 616, West Street, Camden, N.J., U.S.A., manufacturing chemist.

Hooker, Ben., Pear Tree Court, Farringdon Road, E.C., M. Inst. M.E.

Jackson, Saml., Higher Bent Ley, Meltham Mills, Huddersfield, analyst.

Jantzen, Paul, 132, Fenchurch Street, E.C., chemical merchant.

Johnston, W.A., The S.S. White Dental Manufacturing Co., Princess Bay, New York, U.S.A.

Lange, Dr. Martin, Amersfoort, Holland, chemist.

Luthy, Edmund O., c/o Mellwood Distillery Co., Louisville, Ky., U.S.A., distiller.

Muir, Jas. Stanley, Chem. Laboratory, Glasgow University, assistant to professor of chemistry.

Sharpley, Hy., Limber Magna, Ulceby, Lincolnshire, seed crusher.

Squire, Percy, 11, Wine Office Court, Fleet Street, E.C., printing ink manufacturer.

Takayama, Jintaro, Werft Str. 10, Moabit, Berlin, chemist to Japanese Department of Agriculture.

Van der Want, Gerard, Gouda, Holland, mechanical engineer.

Warren, Fiske, 220, Devonshire Street, Boston, Mass., U.S.A., paper manufacturer.

Whewell, W., Irwell House, Dumers Lane, Radcliffe, near Manchester, chemical manufacturer.

Whitaker, H. L., Condong Sugar Mill, Tweed River, N.S.W., analytical chemist.

Wickens, B. Foster, 83, Queen Street, Cheapside, E.C., secretary to Wickens, Pease, and Co.

Woodman, Durand, 52, Broadway, New York, U.S.A., analytical chemist.

Young, Geo., 5, Colinton Road, Edinburgh, student of chemistry.

#### CHANGES OF ADDRESS.

Allen, Wm., 1, o Bournemouth; Evenley Hall, Brackley, Northants.

Beckett, G. H., 1, o Bradford; c/o J. Crosfield and Sons, Warrington.

Bernard, Jas., Journals to Casal das Rollas, Olivaes, Lisbon.

Bowing, Jno., 1, o London; The Cottage, West Tilbury, Essex.

Elborne, Wm., Journals to 2, Richmond Villas, Station Road, Cambridge.

### ERRATUM.

In the September number of this Journal, page 846, line 19 from top of column II., instead of "had to be done" read "had been done."

## Journal and Patent\* Literature.

### I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

Action of Tannin on Iron. L. Manstetten. Chem. Zeit. **14**, 869-870.

L. VIGNON (Chem. Zeit. **14**, 117; this Journal, 1890, 725 and 767), in a note on tannin as an anti-incrustator, expresses the opinion that its use is injurious to iron boilers on account of its corrosive action. The author attacks this view, and while holding no brief for tannin in this capacity, yet gives reason for belief that it has little tendency to attack iron after the first contact, the metal becoming coated and protected from further action. His experiments with iron as a material for vessels used in the extraction of tanning materials show that the quantity of iron taken into solution is inconsiderable, and that, although the first few batches of liquor are discoloured, and have to be filtered through spent tanning matter, subsequent extracts are unaffected. Further, direct experiments, consisting in boiling slips of sheet iron in tannin solutions for different periods, show the rate of attack to be very slow. He concludes that the risk from the use of tannin as an anti-incrusting agent has been much exaggerated.—B. B.

### PATENTS.

Improvements in Lead Tanks, and in the Method of Manufacturing the same. P. J. Davies, London. Eng. Pat. 12,157A, July 31, 1889, *8d*.

See under XI., page 952.

Improvements in and in Apparatus for Concentrating and Evaporating Liquids, and for Burning off Organic Matter therefrom. C. H. Roeckner, Tynemouth; F. L. and R. L. Roeckner, Hemel Hempstead. Eng. Pat. 12,871, August 15, 1889, *8d*.

THE inventors claim novelties of arrangement in four classes of apparatus:—(1.) When boiling fibrous materials or similar matters in pans or trays, they introduce into the apparatus a mid-feather or division, and, by means of agitators, force the liquid to travel round and round, whereby the heat is to be more fully utilised and evaporation from the surface of the liquid facilitated. (2.) When incinerating partially dried and thickened materials, they place them in ovens with circular floors, from the centres of which sets of rotatory agitators or stirrers are made to work, whereby all organic matter can be burned off to any desired extent or reduced to ashes without manual labour. (3.) When constructing apparatus for evaporating much diluted liquids by multiple effect, they place all evaporating surface of their apparatus diagonally or inclined instead of either vertically or horizontally, with a view to obtaining better economical results through facilitated evaporation. (4.) In tubular apparatus for direct evaporation they also place the tube boxes inclined or diagonally, and they cause the weakest liquor to enter the system nearest the fire-grate so that it may meet with the greatest heat at starting.

The specification is illustrated by four sheets of drawings.—B.

\* Any of these specifications may be obtained by post, by remitting the cost price, plus postage, to Mr. H. Reader Luck, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C. The amount of postage may be calculated as follows:—

If the price does not exceed 8 <i>d</i> . . . . .	3 <i>d</i> .
Above 8 <i>d</i> ., and not exceeding 1 <i>s</i> . 6 <i>d</i> . . . . .	1 <i>d</i> .
" 1 <i>s</i> . 6 <i>d</i> ., " " 2 <i>s</i> . 4 <i>d</i> . . . . .	1½ <i>d</i> .
" 2 <i>s</i> . 4 <i>d</i> ., " " 3 <i>s</i> . 4 <i>d</i> . . . . .	2 <i>d</i> .

*Improvements in and relating to Filtering Apparatus.*  
R. C. Gerville, Hamburg, Germany. Eng. Pat. 16,499,  
October 18, 1889. 8d.

THE object of this invention is to provide means for cleaning the surfaces of the filtering material by reversing the direction of the liquid through the filtering substance. This is effected by a tap of peculiar construction, having a hollow plug, by adjusting the position of which the supply of liquid may be shut off, or the filtered liquid drawn off, or the direction of the liquid through the filtering medium reversed. The filter case is preferably circular, and at one point partially encloses the tap. The filtering medium is cemented into the filter casing, and to the top, so as to leave spaces between its front and rear sides, and the top and bottom of the casing, and communicating with the tap. For details of the construction and mode of using the tap the drawings attached to the specification must be consulted. There are six claims.—E. S.

*Improved Apparatus for Use in making Extracts from, and otherwise treating, Soluble or Partially Soluble Substances by Means of Steam Pressure and Heat.*  
A. H. Hobson, London. Eng. Pat. 16,863, October 25, 1889. 8d.

THE improvements relate to apparatus principally designed for use in extracting the soluble constituents of bones, hides, roots, dyestuffs, &c., and generally for treating materials by steam and heat for the elimination of extractive matters and other purposes. The extractor consists of a spherical or other shaped vessel provided with hollow trunnions and mounted to revolve about a stationary tubular axis, and having steam inlet and exhaust passages, and meridionally arranged heating and agitating pipes in connexion with them, and also a perforated jet pipe arranged to inject steam into the mass to be treated.

The extractor having been charged, steam at suitable pressure is admitted to the pipes for heating the charge, and to the jet pipe. The difference of pressure between the generator and the extractor necessary to ensure the efficient action of the steam jet is maintained by an automatic steam cock.—E. S.

*Improvements in Vacuum Pans.* W. K. Bruce, Dundee.  
Eng. Pat. 17,018, October 28, 1889. 8d.

THE vacuum pan is constructed of two readily separable parts, which when the pan is in use are held together by the pressure of the external atmosphere, without the use of bolts. The upper part or dome is provided with a pulley and counterbalance weight, and the lower part is supported on a suitable frame by hollow trunnions, through which the steam supply and exhaust pipes pass. By means of a lever the lower part can be turned about its trunnions to permit of the removal of its contents. By this construction ready access can be had to the interior of the pan for cleaning or other purposes. There are five claims.—E. S.

*Improvements in Apparatus for Evaporating Liquids.*  
E. Theisen, Sinzig, Germany. Eng. Pat. 19,222, November 29, 1889. 1s. 1d.

THE inventor constructs apparatus for the rapid evaporation of liquids in such a way as to cause the liquid together with air or gas to pass through centrifugal apparatus consisting of a number of rapidly revolving discs, fans, or plates, in which the liquid and the gases are brought into close contact either whilst passing through the discs or immediately on issuing therefrom. There are also claims for means of raising the liquid to the apparatus from a lower level, for augmenting the propelling action of the fans, for working several sets together in multiple effect, and for other modifications. The general mode of action will best be understood from the accompanying sketch, which shows a vertical section through one class of apparatus.

THE RAPID EVAPORATION OF LIQUIDS.

The dished plates A A are secured by the arms B to a hollow shaft C, which receives rapid motion by means of the pulley K. The spaces between the discs A communicate through channels L with a stationary tube D surrounding the shaft C, which tube is in connexion with a pipe E through which the liquid is admitted, aided by the screw G secured to the rotatory shaft. The cylindrical chamber F1 supplies the air or hot gases through the pipe F and also carries the casing I of the centrifugal apparatus as well as a stationary dished plate H. On the mixture of liquid and gases issuing through the plates A a rapid evaporation takes place, the vapours are led away, whilst the unevaporated liquid returns through the pipes F1 and E for repeated manipulation. The specification covers seven claims and there are nine sheets of drawings.—B.

*Improvements in Filter Presses.* S. H. Johnson and C. C. Hutchinson, Stratford. Eng. Pat. 8544, June 3, 1890. 8d.

THE object of these improvements is threefold:—

(1.) To facilitate the escape of the filtered liquid after having passed through the filtering cloths. This is done by constructing the partition plates with their surfaces formed of projecting studs with reticulated interspaces between them. This construction also increases the accessibility to the surfaces for cleaning.

(2.) To preserve the filtering cloth by preventing undue wear at certain points. This is effected by the employment of hydraulic lipped packings in the rims of the filter plates, whether moulded with the lips or the lips formed by the operation of closing the joints.

(3.) To secure tight joints in the inlet, outlet, and washing passages. This is done by "an elastic packing ring with lips projecting so as to come into gentle contact with the joint surfaces of the adjoining lugs and so contrived that the pressure due to the working of the machine becomes the effective agent."—E. S.

*Improvements in Pulverising Mills.* H. H. Lake, London.  
From V. L. Rice, New York, U.S.A. Eng. Pat. 9809,  
June 24, 1890. 8d.

A CHAMBER made of iron, and in the form of a pan, contains a steel ring which forms one of the grinding surfaces. Round the interior of the ring three rolls suitably mounted on shafts are caused to revolve. The centrifugal force generated by the revolution of the rolls and their shafts causes them to swing outwardly into contact with the ring, and at the same time causes them to turn on their axes as they revolve round the chamber. When the rolls are at rest they fall away from the wall of the chamber. Some of

the rolls are provided preferably with a spiral flange which lifts the pulverised material and causes it to be distributed over the surface of a circular screen, mounted on the upper edge of the chamber and constructed with a slight outward taper. When pulverised to the required fineness, the material passes through the screen and falls into the hopper. The two drawings accompanying the specification must be consulted for details of construction. There are eight claims.—E. S.

## II.—FUEL, GAS, AND LIGHT.

*On a Violet Colouring Matter from Residues of Gas Purifiers or Illuminating Gas.* R. Gasch. Jour. f. Gasbeleuchtung, **33**, 304—306.

This colouring matter is the iron salt of potassium carbonyl-ferrocyanide. Illuminating gas in its passage from the purifier to the gas holder is led through an alkaline solution of ferrous oxide; the solution is acidified and the ferrocyanide precipitated by zinc or ferrous sulphate. The filtrate gives the violet colour on the addition of ferric chloride before the sulphocyanide reaction appears. If, however, the solution contains only a little of the former, the sulphocyanide reaction appears first and the violet later. The colouring matter may be obtained by precipitation with sodium chloride. The violet colouring matter is obtained from gas purifier residue by extraction with weak soda or strong ammonia and precipitation of the acidified solution with zinc or ferrous sulphate. If the latter is used the sulphate should be added until the blue precipitate ceases and a white one appears. The violet is precipitated from the filtrate by ferric chloride.—A. L. S.

*On Purifying Material.* E. Schilling. Jour. f. Gasbeleuchtung, **33**, 322—326.

It is well known that an analysis of a gas purifying mass does not indicate its value. Factors that require to be taken into consideration besides the composition of the material, are: weight, size of grain, moisture, the substance for rendering the mass more penetrable, the depth of the layers, the velocity and difference in pressure of the gases previous to entering and after leaving the purifier. In order to find the highest value of a certain purifying mass, the author passed a current of pure sulphuretted hydrogen over the finely powdered material, retaining the water which was produced by phosphoric anhydride. Even after passing the current through for 20 hours, complete saturation did not take place. The chief action was over after three hours. Pure ferric hydroxide absorbs on an average after the first saturation, 30.77 of sulphur, different varieties of bog-iron ore 11.2—28.41; the theoretical amount of sulphur corresponding to the amount of iron oxide present varied from 18.06—42.69. From this it will be seen that in no case, not even that of pure ferric hydroxide, was the maximum absorption equal to that theoretically possible. And it does not appear that there is any relation between the amount of iron in the material and the amount of sulphur absorbed.

Referring to the difference in absorbing capacity as influenced by certain physical conditions the author points out that the quantity of sulphur taken up was doubled by interspersing wood shavings in the mass.—A. R.

*Cyanogen in Gas Manufacture.* W. Leybold. Jour. f. Gasbeleuchtung, **33**, 336—341. (See Appendix, "The Estimation of Cyanogen in Gas," page 979.)

The amount of nitrogen contained in coal varies from about 1.06 to 1.50 per cent. Knnblanch found that for every 100 parts of nitrogen in the coal there were found: 31.36 in the coke, 10—14 as ammonia, 1.5—2 as ferrocyanogen (in the purifying material), 1.0—1.3 in the tar; the remaining 46—56 parts would probably be in the illuminating gas.

The cyanogen in the crude gas exists as ammonium cyanide, which being very volatile even at 36° C. passes on with the gas through the condensers and scrubbers till it reaches the purifiers without much loss; a little however being found in the liquors condensed as ammonium sulphocyanide, and owing to the power of the cyanide to dissolve the iron of the apparatus, as ferrocyanide. In one case there was found in the liquor from the hydraulic main per litre 23 grms. of ammonium chloride, .88 gm. of sulphocyanide, and .11 gm. of ferrocyanide; in the liquor from two pair of atmospheric condensers .52 gm. and .33 gm. of sulphocyanide, .05 gm. and .11 gm. of ferrocyanide, .12 gm. and .09 gm. of unaltered cyanide; in the water condenser 1.27 grms. of sulphocyanide, .44 gm. of ferrocyanide, and .25 gm. of cyanide. In the scrubber even, very little cyanogen was found, the ammonium cyanide, though readily soluble in water, being decomposed by the carbonic acid into ammonium carbonate and free hydrocyanic acid.

The following tables indicate the amount of hydrocyanic acid retained by the various parts of the gasworks apparatus. The coals employed were of five different sorts, carbonised in separate retorts, and so arranged that the gas mixed in the hydraulic main.

TABLE I.—CYANOGEN IN THE GAS.

Source.	Grms. HCN per 100 cbm.	Per Cent. HCN by Vol.	Removal of the HCN	
			By Weight.	Per Cent.
Hydraulic main.	203.4	0.166	Grms. 16.3	8.02
After condensers	187.1	0.152	13.5	6.55
After scrubber ..	173.6	0.142	114.1	65.15
After purifiers ..	59.5	0.048	39.7	19.55
Holders .....	19.8	0.016	19.8	9.73
			203.4	100.00

TABLE II.—CYANOGEN IN THE GAS.

Source.	Grms. HCN per 100 cbm.	Per Cent. HCN by Vol.	Removal of the HCN	
			By Weight.	Per Cent.
Hydraulic main.	265.9	0.217	Grms. 10.0	3.76
After condensers	255.9	0.209	4.3	1.62
After scrubber ..	251.6	0.205	119.9	45.00
After 1st purifier	131.7	0.107	48.4	18.20
After 2nd purifier	83.3	0.067	21.7	8.16
After 3rd purifier	61.6	0.050	20.4	7.67
Holders ....	41.2	0.033	41.2	15.50
			265.9	100.00

These tables show that from 56 to 71 per cent. of the total amount of cyanogen formed is retained in the iron-oxide purifiers; Table II. also proving that the largest amount is found in the first purifier. The more purifiers employed, the larger is the yield of cyanogen, for even in the absence of sulphuretted hydrogen it is still absorbed by oxide that has been used, whether revived or not.

The cyanogen is recovered as prussian blue; and to obtain a spent oxide containing a considerable amount, it is advisable to retain one purifier as No. 1 for a long time after it has ceased to take up sulphuretted hydrogen, the rest of the purifiers being managed as usual. By this means it is possible to obtain from 8 to 10 per cent. of prussian blue. The speed of the gas has great influence on the amount recoverable; the purifiers, therefore, should be as large as possible.

When hydrocyanic acid is passed through a layer of iron oxide as employed in gasworks, it is not absorbed; but if the material is first saturated with sulphuretted hydrogen, so as to form iron sulphide, the greater part is taken up, even after revivification. Iron cyanide is produced, which, in presence of air, is converted into iron ferrocyanide or prussian blue; this, however, is not of constant composition, but is a mixture of various compounds, some of which, especially when the yield is high, contain ammonia in combination. A trace of sulphocyanogen is generally found at the same time, and when the scrubbing has been inefficient, so that the gas enters the purifiers containing large quantities of ammonia, the yield of sulphocyanogen is often higher than that of blue.

To imitate these latter conditions, a mixture of hydrocyanic acid and ammonia was passed through an oxide purifier previously saturated with sulphuretted hydrogen. The following figures were obtained, the speed of the gas being lower in the second case:—

	Per Cent.	Per Cent.
Water.....	26.62	32.33
Sulphur.....	24.98	18.98
Prussian blue.....	1.71	3.57
Ammonium sulphocyanide.....	3.03	6.25
Ammonia.....	2.05	2.08

Ammonia has also the effect of increasing the yield of sulphocyanogen at the expense of the ferrocyanogen. By substituting ammonium sulphide for the free ammonia, the following result was obtained:—

	Per Cent.
Water.....	33.02
Sulphur.....	11.39
Prussian blue.....	5.38
Ammonium sulphocyanide.....	4.40
Ammonia.....	0.75

A revived purifier was moistened with ferrous sulphate solution (10 per cent.), to keep it in an acid condition, and the mixture of hydrocyanic acid and ammonia passed over it. The amount of prussian blue found was 3.32 per cent., and of ammonium sulphocyanide 2.61 per cent., thus showing that a neutral condition is the most favourable for the formation of the former. By making the oxide alkaline with soda, and then treating with hydrocyanic acid, the reactions became more complicated:—

	Per Cent.
Water.....	32.52
Sulphur.....	6.39
Prussian blue.....	0.93
Sodium sulphocyanide.....	0.73
Sodium cyanide.....	1.13
Sodium ferrocyanide (cryst.).....	0.89

The author's experiments show that the percentage of blue contained in the spent oxide, and, therefore, its marketable value, may be greatly increased by removing the free ammonia from the gas as thoroughly as possible before it enters the purifiers. In one works where new scrubbers were erected the yield rose from 3.0 per cent. to 6.23 per cent., the sulphocyanogen falling from 5.96 per cent. to 3.22 per cent., while with suitable oxide, by allowing the gas to remain in contact with the material for some time, it may rise as high as 10.32 per cent.

From the above tables Nos. 1, and 11., it will be seen that of the total cyanogen reaching the purifiers, only 65 and 85 per cent. is recovered. To avoid this loss, which in large works is considerable, a process has been devised by Knublauch, in which the gas is passed through a scrubber containing a mixture of soda and ferrous sulphate solution, the best position for which is next the hydraulic main.

—F. H. L.

*On the Use of Magnesium Chloride Solution for filling Gas Meters.* W. Leybold. Jour. f. Gasbeleuchtung, **33**, 424.

The author recently examined an old gas meter, which had been in use for several years, the drum of which was made of britannia metal. The solution was found to be of

the same specific gravity as when first put in (22° B.), and was perfectly clear; but on the walls of the meter there was a heavy brown deposit consisting of zinc sulphide, iron sulphide, iron cyanide, lead hydrate, and tin oxide. The zinc must be derived from the vessels used to prepare and keep the magnesium chloride, none entering into the composition of the meter. On opening the drum, the britannia metal was found to be unattacked, but the leaden U-tube as well as the soldering was eaten away.

The author recommends the use of magnesium chloride only when the gas is free from ammonia, the action of the latter being to form magnesium carbonate, which is insoluble in the solution of the chloride and separates out in thick crusts. Meters filled as above should be distinctly marked, to avoid subsequent addition of glycerin.—F. H. L.

*The Weathering of Coal.* Busse. Deutsche Töpfer und Ziegler Zeit. 1890, **21**, 353.

COAL, when exposed to the weather, is acted on by the oxygen of the air up to a definite limit; it combines with the free hydrogen of the coal to form water, and with a part of the carbon to form carbonic acid. When the limit is reached a certain amount of oxygen is yet taken up and mechanically held by the coal. Thus, as the result of weathering, coal loses some of its combustible constituents, and gains in weight owing to the absorption of oxygen. This may amount to as much as 4 per cent. on the original weight of the coal. The effect of weathering is greater the smaller and the more porous the lumps are.—A. L. S.

## PATENTS.

*Improvements in and Connected with the Manufacture of Illuminating Gas from Coal.* J. H. R. Dinsmore, Liverpool. Eng. Pat. 7714, May 27, 1887. Amended May 24, 1890. 8d.

THE emendations cannot be clearly understood without reference to the original specification, which must be consulted for details. Briefly stated, the process now claimed is carried out by "distilling the coal in closed retorts, heating the gas so produced, and then subsequently cooling it upon leaving the apparatus."—O. H.

*Improvements in or Appertaining to Appliances for Burning Hydrocarbons.* J. Wilson, New York, and A. Mason, Brooklyn, U.S.A. Eng. Pat. 10,660, July 2, 1889. 8d.

THE improvements relate to contrivances for burning hydrocarbons (petroleum and other oils and fatty substances, gases and vapours, &c.) in steam boiler and other furnaces, for details of which the original specification must be consulted.—F. S. K.

*Improvements in the Manufacture of Illuminating Gas.* F. J. Jones, St. Albans. Eng. Pat. 11,624, July 20, 1889. 8d.

THE hot gases (water-gas) resulting from the action of superheated steam on coke are passed through a charge of coal moving continuously downwards. The mixture of gases, tarry matter, and other vapours so obtained is at once passed through a superheater and the resulting gas then purified in the ordinary way. The apparatus employed is described in Eng. Pat. 19,721 of 1889.—H. K. T.

*Improvements in or Relating to the Manufacture of Gas from Atmospheric Air.* J. F. L. Monier, Paris, France. Eng. Pat. 12,043, July 29, 1889. 8d.

THE object of the present application is to provide a new apparatus for making gas by means of the earthenware of atmospheric air, and which offers certain advantages over the various patterns of the same style of apparatus at present in use.

"The fundamental principle of the apparatus consists in the application of an ejector based upon the Giffard system with a draught of air by means of a jet of steam, and planned in such wise that, given an effective minimum pressure, for example, equivalent to  $1\frac{1}{2}$  kilos., while the volume of air drawn along shall correspond to the required supply, the carburetted air thus transformed into illuminating gas will issue at the outlet of the apparatus under a pressure of water equivalent to at least 70 mm., whereby gas can be carried to great distances and up to any desired altitude."

The gas is produced as follows: Air, by means of a steam ejector, is passed into a water-cooler, where the steam is condensed, and then into a dome or bell fitted at the upper part of the apparatus and suspended over a pulley; the weight of the bell must be proportionate to the pressure of steam forcing air into the carburettor, and its vertical guidance is effected by means of an iron rod, fitted to the bottom of the reservoir, and extending into a pipe fixed to the upper part of the bell; the lower extremity of this pipe is perforated to allow the surplus air to escape at a time when, owing to pressure, the bell might be caused to ascend too high. From the bell the air is conducted into the carburettor through a pipe fitted at the lower part of the apparatus and immersed in the hydrocarbon. This pipe is made in the shape of a double coil and is provided along its entire length with a number of perforations through which the air escapes, and, passing upwards through a perforated tray immersed in the hydrocarbon, is finally carried off to the gas supply pipe.

The apparatus is easy of application in establishments where a steam engine is fitted; for application where no steam engine is available a small steam generator has been designed.—F. S. K.

*Improvements in Air and Gas Comminglers.* W. W. Popplewell, London. From J. M. Mitchell, New York, U.S.A. Eng. Pat. 13,526, August 27, 1889. *Sd.*

This apparatus consists of two rotary blowers coupled together by which air and gas are charged into the same conduit. An arrangement is provided by which the relative volumes of air and gas can be altered.—H. K. T.

*Improvements in and relating to Gas Washers.* G. E. Saville, Millwood. Eng. Pat. 15,740, October 8, 1889. *Sd.*

The gas enters a trough or bell inverted in a closed tank through which ammoniacal liquor flows and is drawn through perforations in the lower sides of the inverted trough by the exhauster. Should the speed of the latter become accelerated, the liquor, which is supplied freely, will be drawn up between the sides of the trough and the tank and so prevent excessive exhaustion in the retorts, &c., and consequent mixing of furnace gas with the coal gas. The lower part of the tank communicates with a cylindrical vessel open at the top for regulating the height of the liquor. In the centre of this regulator is a funnel, over the edge of which the liquor overflows and is led away.

—H. K. T.

*Process for obtaining Salts of Thorium, Zirconium, and like Metals from their Ores or from Waste Residues of Hoods used for Incandescent Gas Lighting.* O. Imray, London. From W. MacKean, Paris, France. Eng. Pat. 16,555, October 19, 1889. *6d.*

See under VII., page 941.

*Apparatus for Producing an Inflammable Gas by Carburation of Air.* A. A. Fritz, Brussels, Belgium. Eng. Pat. 17,140, October 29, 1889. *1s. 1d.*

A liquid hydrocarbon is supplied under pressure to a reservoir, passing thence to a boiler, the amount so passing being regulated by a tap actuated by the bell of a gasometer. From the boiler, which is heated by Bunsen

burners, the hydrocarbon issues in the form of vapour through injectors and draws air with it, the air entering through check valves, which close against any outflow. The mixed air and vapour pass into the gasometer, thence to a scrubber composed of layers of coke, supported on wire gauze, and so to the main. The rate of consumption determines the yield of hydrocarbon, since, when the gasometer rises, the supply of hydrocarbon to the boiler is cut off. Any liquid which drains from the scrubber is returned to the reservoir. Drawings descriptive of the different forms of the apparatus accompany the specification.

—H. K. T.

*Improvements in Saturating Coal Gas, Air and other suitable Gases with Hydrocarbon Vapour for Limelight and other Purposes.* A. W. Scott, Weston-super-Mare. Eng. Pat. 17,378, November 2, 1889. *8d.*

This apparatus consists of a closed vessel filled with cotton-wool or other porous material, and furnished with an inlet and outlet tube. A clear path is maintained between the two tubes by means of a skeleton tube of wire similar to those used for lining india-rubber tubing. The vessel is immersed in a water-bath. It is charged by filling it with benzene or commercial "benzoline," or any hydrocarbon boiling between  $100^{\circ}$  and  $200^{\circ}$  F., any liquid unabsorbed by the cotton-wool being drawn off. The apparatus is used for saturating oxygen previous to its passage through an ether saturator or for saturating hydrogen or coal-gas for the usual oxy-hydrogen limelight.—H. K. T.

### III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

*Nononaphthene and its Derivatives.* M. I. Kononov. J. Russ. Chem. Soc. 22, 4—23 and 118—148.

THIS is a first detailed study of one of the members of the naphthene series recently found in Caucasian naphtha. The fraction of Baku kerosin boiling at  $135^{\circ}$ — $137^{\circ}$  was found to consist of the hydrocarbon  $C_{10}H_{18}$ , and served the author as material for the study. Three specimens of the same hydrocarbon differed but slightly in their specific gravity, having at  $20^{\circ}$  respectively a density of 0.7652, 0.7647, 0.7664. Like all other naphthenes it does not deviate the plane of polarisation; it is insoluble in water, but very hygroscopic, and can be distilled almost without decomposition.

Not only fuming sulphuric acid on heating, but even dilute sulphuric acid at the ordinary temperature acts upon nononaphthene very considerably, evolving sulphur dioxide and becoming black and thick. Thus Mendeléeff's advice to avoid chemical purification of naphtha hydrocarbons by means of sulphuric acid appears to be well founded.

The final result of the reaction of fuming sulphuric acid on nononaphthene is, according to the author, undoubtedly pseudocumene mono- and di-sulphonic acids, accompanied by some tar-like oil.

Bromine acts on nononaphthene in direct sunlight or on heating strongly. In presence of a small quantity of aluminium bromide, bromine forms with nononaphthene a crystalline bromide, as with all naphthenes containing more than  $C_7$  in the molecule. These needle-like crystals are formed even when the nononaphthene is obtained by hydrolysing chloronaphthyl, i.e., when it is absolutely free from any aromatic substance. The crystalline bromide proved to be  $C_{10}H_{17}Br_2$ , melting at  $227^{\circ}$ — $228^{\circ}$ ; tribromopseudocumene ( $C_{10}H_{15}Br_3$ ) melts at  $225^{\circ}$ — $226^{\circ}$ . The author assumes this slight difference in the temperature of melting is caused by the admixture of  $C_{10}H_{17}Br_2$  with the former, which melts at  $240^{\circ}$ — $241^{\circ}$ . It is not improbable that a methyl-group is eliminated by the action of bromine on the naphthene, and the action of nitric acid confirms this.

Chlorine combines with nononaphthene under ordinary conditions, whilst when in excess and in direct sunlight it reacts with a slight explosion; the outcome being mono- and dichloride,  $C_9H_7Cl$  and  $C_9H_6Cl_2$ .

Fuming nitric acid hardly affects the hydrocarbon, the nitro products are formed, but in so small quantity that they may be ascribed to the impurities of the hydrocarbon. The author tried dilute nitric acid (sp. gr. = 1.38 + 2 vols. of water), and succeeded in obtaining, on heating it with the hydrocarbon in sealed tubes, a nitro-product containing only  $C_9$  in a molecule— $C_9H_7NO_2$ , besides an acid solution containing products of oxidation. The former is a yellowish oil, boiling very constantly at  $218^\circ$ — $220^\circ$ , and having a feeble smell, dissimilar from that of aromatic compounds. Under the reducing action of hydrogen, it becomes a volatile alkaline liquid, resembling *conine* and of the same formula (propylpiperidine),  $C_8H_{15}NH_2$ . It is strongly alkaline, fuming like ammonia on neutralising it with hydrochloric acid; boils at  $172^\circ$ — $177^\circ$ , specific gravity at  $0^\circ$  = 0.8727, at  $20^\circ$  = 0.8717 (*conine* boils at  $167^\circ$ — $168^\circ$ , specific gravity at  $0^\circ$  = 0.8625). This amine combines with hydrochloric acid, platinum chloride, and sulphuric acid, giving respectively fixed salts; chloride,  $C_8H_{15}NH_2HCl$ , crystallising from hot aqueous solution in yellow tablets and needles. The platino-chloride,  $(C_8H_{15}NH_2 \cdot HCl)_2PtCl_4$ , is hardly soluble in water.

The sulphate,  $[C_8H_{15}NH_2]_2H_2SO_4$ , on being analysed proved this formula. The author ascribes a great importance to the study of these two classes of nitro- and amido-compounds, as they may serve for obtaining a series of homologous hydrocarbons.

On the other hand, the splitting of the molecule by the action of nitric acid, bromine in presence of aluminium bromide, and probably also by the action of sulphur, suggests to the author an explanation of the oxidation of the hydrocarbon. By the action of oxidising agents, nononaphthene never gives acids containing  $C_9$  in the molecule; the acid solution accompanying the nitro-product was found to be a mixture of acids, such as terephthalic, acetic, probably butyric, and some others.

All efforts to reduce nononaphthene into a corresponding paraffin by the action of hydriodic acid failed, although the author still believes such reduction possible.

**Derivatives of Nononaphthene.**—The *Monochloride*,  $C_9H_7Cl$ , is formed by passing dry chlorine into the vapour of nononaphthene from Caucasian naphtha. At least two isomeric varieties are obtained:—

1. Boiling at  $185^\circ$ — $188^\circ$ , sp. gr.  $D_{20}^{20}$  = 0.9339.
2. Boiling at  $182^\circ$ — $184^\circ$ , sp. gr.  $D_{20}^{20}$  = 0.9304.

Probably it contains the admixture of corresponding paraffin chlorides boiling at the same temperature. They are oily liquids with a smell like camphor, and a very sharp taste. They are also lighter than water, and can be distilled under the ordinary pressure.

On heating with caustic alkali, hydrochloric acid is obtained, and  $C_9H_{16}$  with products of decomposition. Water produces a similar effect, partly exchanging hydroxyl (HO) for chlorine, and giving an alcoholic compound. Bromine in presence of aluminium bromide acts upon the chloride and gives a crystalline substance, probably tribromopseudo-cumene.

**Dichloride**,  $C_9H_6Cl_2$ , is capable of yielding 2 mols. of hydrochloric acid, and becoming  $C_9H_{14}$ —the first hydrocarbon of the terpene series obtained from naphthenes.

**Iodononaphthene**,  $C_9H_7I$ , is formed on heating the chloride ( $185.5^\circ$ ) with hydriodic acid. It is a heavy colourless liquid, almost insoluble in water, boiling at  $108^\circ$ — $111^\circ$ , and could not be solidified. Sp. gr.  $D_{20}^{20}$  = 1.4041.

**Nononaphthyl Acetate**,  $C_9H_7CO_2CH_3$ , formed on heating silver acetate with the chloride of the hydrocarbon; boils at  $208.5^\circ$ , sp. gr.  $D_{20}^{20}$  = 0.9200. Along with it is formed a considerable amount of unsaturated hydrocarbon,  $C_9H_{16}$ , boiling below  $120^\circ$ .

**Nononaphthyl Alcohol**,  $C_9H_{17}OH$ , is obtained by the action of silver monoxide on the acetate of the hydrocarbon. Its agreeable smell resembles that of the tertiary alcohols; it boils at  $189^\circ$ — $192^\circ$  and its sp. gr.  $D_{20}^{20}$  = 0.8972. Some other alcohols homologous with this one had been already obtained, such as  $C_8H_{15}OH$ , by Pautinsky and Jakevkin, and  $C_{11}H_{23}OH$  by Markovikov and Ogloblin. It is scarcely soluble in water, but is very hygroscopic and forms naphthylates with sodium, barium and, probably, silver.

**Nononaphthyl Ether**,  $(C_9H_{17})_2O$ , is obtained by the action of silver monoxide on the iodide; it boils at  $294^\circ$ — $297^\circ$ . It is a thick liquid, and can be distilled over metallic sodium; sp. gr.  $D_{20}^{20}$  = 0.8662 (lower than that of alcohol).

**Nononaphthylene**,  $C_9H_{16}$ , was first obtained and named by Markovikov. It is formed from the chloride of nononaphthene by the action of silver acetate. There are at least two isomeric hydrocarbons: 1, boiling at  $135^\circ$ — $137^\circ$ , sp. gr. =  $D_{20}^{20}$  = 0.7962; and 2, boiling at  $131^\circ$ — $133^\circ$ ; colourless liquids with a smell similar to that of turpentine and quite different from that of naphthenes; it resembles in its physical properties campholene from campholic acid. It combines readily with 2 atoms of bromine, showing a marked increase of temperature, but the resulting bromide readily yields hydrobromic acid. On standing with water in presence of a small amount of sulphuric acid it forms nononaphthyl alcohol. In strong sulphuric acid it dissolves completely. On heating with hydriodic acid in sealed tubes it forms ordinary nononaphthene. In presence of suitable oxidising agents it gives the same products as the above alcohol, i.e., a mixture of acids containing less than  $C_9$  in a molecule, such as acetic, succinic, and others. In short, these hydrocarbons of the general formula,  $C_nH_{2n-2}$ , of the naphthene series stand in the same relation to naphthenes as olefines stand to paraffins in the normal series.—N. W. T.

#### *The Occurrence of Phenol and Pyridine in Brown Coal-Tar.* T. Rosenthal. Chem. Zeit. 14, 870.

ALTHOUGH it is stated in the text-books that phenol is a constituent of brown coal-tar, yet the preparation of the pure crystalline substance therefrom appears not to have been hitherto effected. It may be obtained by the following process: Light oil or first runnings is shaken with 0.5 per cent. of its weight of caustic soda dissolved in water to make a 10 per cent. solution. After removing traces of oil clinging to the alkaline solution of phenol thus obtained, by blowing steam through it, the tar acids are liberated by the addition of dilute sulphuric acid, and purified by repeated distillation, towards the end over chromic acid, and finally over white lead. A considerable proportion distils below  $190^\circ C.$ , and from it crystals of phenol separate on standing, which melt at  $36^\circ C.$  after recrystallisation. The purity of the substance was proved by the analysis of the derivatives tribromophenol and the potassium salt of paraphenol-sulphonic acid.

Pyridine has not previously been obtained from this source; it is present in very small quantities. Six thousand kilos. of light oil shaken out with 50 kilos. of sulphuric acid of 20 per cent. strength gave about 10 kilos. of the crude base. By repeated rectification, using a four-bulb dephlegmator, 200 grms. boiling below  $120^\circ C.$  were obtained. Further purification by means of the ferrocyanide gave a specimen of pyridine boiling at  $115^\circ$ — $117^\circ$ , the purity of which was verified by analysis of its double salts with platinum and gold chlorides.—B. B.

#### *Notes on the Manufacture of Mineral Lubricating Oil.* A. Veith. Chem. Zeit. 14, 901—902 and 942—943.

THE importance of the mineral lubricating oil industry may be gauged by the fact that there are now prepared from the crude material oils of all grades, and adapted for every kind of machinery, and capable, if judiciously chosen, of completely replacing the more costly fatty oils hitherto in use. The mere distillation of the less volatile portion of

petroleum failed to yield a thoroughly satisfactory product, as a certain amount of "cracking" took place in consequence of the contact of the vapour of the oil with the heated sides of the still causing the formation of evil-smelling products of low viscosity. About 1870 the use of superheated steam was adopted, improvement in the quality of the material at once taking place, and fairly good results were obtained by even the early and more primitive appliances, though the oil still left a good deal to be desired. The cause of the efficacy of superheated steam seems to be its mechanical action separating and protecting the particles of oil vapour from local overheating. Consideration of the best material for the retort, temperature and means of condensation led to the evolution of modern plant. Turning first to the still proper, it was found that cast iron when of the necessary thickness was too slow in heating and cooling, and too poor a heat conductor for economical use, and wrought iron was therefore substituted; vertical retorts worked badly owing to the considerable condensation that took place on their upper parts, and the consequent tendency of the oil to trickle back down the heated walls of the still, and retorts of elliptical section set horizontally with a wide tube leading quickly away and downwards for the conveyance of the evolved vapours were adopted in place of them. The form of superheater varies in different factories, but speaking broadly the question of the best material for the tubes is the most weighty, and may be answered thus: Cast iron does not readily oxidise and burn away, but is liable to crack with sudden changes of temperature; the reverse is true of wrought iron; in consequence of these properties the author recommends the use of wrought iron tubes protected with cast iron cast round them as best meeting the requirements of the case. The temperature of the superheated steam is  $220^{\circ}$ – $270^{\circ}$  C., and empirical rules rather than the pyrometer are relied on for obtaining and maintaining it. The condensation of the oil is effected in a large worm with thin walls cooled in air instead of water, and having openings at intervals along its length; by the use of this device, instead of obtaining a single product whose viscosity and flashing point are not particularly high, several different oils are got, the heaviest portion condensing in the portion of the worm nearest the still, and the lighter products after further condensation in the order of their volatility. The lightest of all is condensed in a second worm cooled by water and collects together with the water from the superheated steam. The automatic separation of most of the oil from the water with which it is associated saves time, inasmuch as the oil can be at once refined without waiting for separation by ordinary means.

—B. B.

*The Distillation of Rosin in Vacuo.* C. A. Bischoff and O. Nastvogel. Ber. 23, 1919–1923.

ROsin consists chiefly of a mixture of a hydrocarbon  $C_{20}H_{32}$ , which is probably the same as that described by Deville and Ribau under the name of "colophene," and of an acid  $C_{20}H_{32}O_2$  isomeric with sylvic and pimaric acids, which may be called "isosylvic acid."

The products obtained from the distillation of rosin under atmospheric pressure are the result of complete decomposition occurring during the process, the average yield being as follows:—60 grms. rosin distilled:—

	Grms.	Boiling Point.
Spirit (and trace of water).....	8.0	$108^{\circ}$ – $200^{\circ}$
Viscid, clear oil .....	9.8	$206^{\circ}$ – $360^{\circ}$
Heavy oil.....	16.6	
Pitch (insoluble in alcohol).....	19.0	
Uncondensable gas.....	6.6	

Both the spirit and the oil are readily soluble in caustic soda, from which solution hydrochloric acid throws down white precipitates.

For the distillation in vacuo, an initial pressure of 50 mm. was employed, which owing to the evolution of gas quickly rose to 110 mm. From 24.3 grms. of rosin distilled, 19.8 grms. of distillate were obtained, together with 1.4 grm. of pitch insoluble in alcohol, and 3.1 grms. of gas. The distillate was almost insoluble in cold caustic

soda, but soluble in hot alcohol, being reprecipitated on the addition of water; it was also found to be insoluble in ether and benzene. It was then dried and distilled in air, the first drops coming over above  $360^{\circ}$ , whereas ordinary rosin oil starts at  $108^{\circ}$ . The distillate was collected in three portions, no decomposition being noticeable during the process. The middle fraction was the largest, and consisted of a tacky oil with a smell resembling turpentine; analysed it gave results coinciding with a formula  $C_{44}H_{66}O_3$ . This formula contains two molecules of water less than the so-called "abietic acid,"  $C_{44}H_{64}O_3$ . The substance had neither the character of an acid, aldehyde, ketone, or alcohol, but appeared to be an anhydride; by repeated distillations in vacuo it seemed to be split up into several components.

On repeating the experiments with rosin that had been kept over concentrated sulphuric acid and phosphoric anhydride for three weeks, it was found that water was always obtained on distillation, showing that it must be chemically combined in the rosin. This was then distilled at a pressure of 30 mm., and found to melt at  $69^{\circ}$ – $130^{\circ}$ . First distillation:—

	Per Cent.
Water and spirit.....	11.4
Oil.....	75.2
Pitch.....	6.9
Gas and loss.....	6.6

On heating to  $150^{\circ}$  to remove water, the oil lost 1.5 per cent. Second distillation:—

	Per Cent.
Up to $200^{\circ}$ .....	5
Up to $250^{\circ}$ .....	65
Up to $300^{\circ}$ .....	13
Up to decomposition.....	9
Pitch.....	5
Gas and loss.....	3
	100

The second portion ( $200^{\circ}$ – $250^{\circ}$ ) was redistilled and gave:—

	Per Cent.
Up to $200^{\circ}$ .....	6.4
Up to $216^{\circ}$ .....	19.0
Up to $219^{\circ}$ .....	9.3
Up to $223^{\circ}$ .....	5.4
Up to $225^{\circ}$ .....	6.3
Up to $245^{\circ}$ .....	8.2
$248^{\circ}$ – $250^{\circ}$ .....	35.0
Loss.....	10.4

The fraction  $248^{\circ}$ – $250^{\circ}$  rectified 10 times and analysed, gave results coinciding with the formula  $C_{40}H_{58}O_3$ , and is probably isosylvic anhydride. It solidified in a short time to a hard colourless mass of very fine crystals, easily soluble in alcohol and ether. The alcoholic solution rotated the ray of polarised light to the right  $[\alpha]_D = +63^{\circ}$  (sylvic acid gives  $[\alpha]_D = -53^{\circ}$ ; Haller, Ber. 18, 2166; this Journal, 1886, 25). By repeated solution in caustic potash and precipitation with dilute acetic acid, a white powder was obtained, melting between  $60.5^{\circ}$  and  $62.5^{\circ}$ , and soluble in weak ammonia, which on analysis gave results coinciding with a formula  $C_{20}H_{30}O_2$ . This acid is therefore isomeric with sylvic acid. In common with its isomer, it has the property of giving a red-violet colour on the addition of concentrated sulphuric acid to its solution in acetic anhydride, which is removed by water, colourless flocks separating out.

The next largest fraction distilled at  $216^{\circ}$ – $219^{\circ}$ , and consisted chiefly of hydrocarbons of the formula  $C_{10}H_{16}$ ; by repeated distillation it can be so far purified as only to contain about 1 per cent. of oxygen.

"Colophene" boils at  $318^{\circ}$ – $320^{\circ}$ , in vacuo at  $218^{\circ}$ – $220^{\circ}$ , apparently showing that this substance is a diterpene,  $C_{20}H_{32}$ .

It is specially to be remarked that "colophene" and isosylvic acid, the two chief constituents of rosin, the latter of which is possibly formed during the distillation from the original sylvic acid, are very similar in their composition.

—R. H. L.

*Contributions to the Study of the most Volatile Portion of Coal Tar.* J. Biehinger. Jour. f. Gasbeleuchtung, **33**, 341—345 and 358—369; also Dingl. Polyt. J. **276**, 78 *et seq.*

THE contradictory statements published as to the components of this portion of tar, are probably due to the fact that the investigations have been conducted on products which have been previously submitted to the action of acids and alkalis. To avoid errors introduced in this way, the author's experiments were carried out on that portion of 90 per cent. English benzene which boils between  $30^{\circ}$  and  $80^{\circ}$ , and afterwards on some specially prepared fractions boiling, No. 1 between  $50^{\circ}$  and  $60^{\circ}$ , and No. 2 between  $60^{\circ}$  and  $70^{\circ}$ , sent him by Dr. Häussermann from the chemical works at Griessheim.

In common with previous experimenters, the author found that fractional distillation through Le Bel-Henninger's tubes, or through a six-bulbed apparatus filled with glass beads, even when repeated several times, was not competent to split up the substance satisfactorily, decompositions appearing to occur which altered the boiling points.

By allowing the crude products to settle, or better by fractionation, they were found to separate into two distinct layers, the lower consisting chiefly of carbon bisulphide. The separation, however, was not sufficiently complete to allow of exact results being obtained. The only other methods available were to remove one well-known constituent at a time, or to separate the substances into groups.

To test for carbon bisulphide, the first runnings, or impure benzene, are treated with alcoholic ammonia, and allowed to rest for a time. If the amount present is not extremely small, ammonium sulphocyanide separates out in crystals, which may be extracted with water, and after acidification identified by ferrie chloride. Or by adding caustic potash dissolved in absolute alcohol, the carbon bisulphide may be converted into potassium xanthate, which may be dissolved out by water and identified by the formation of the yellow cuprous xanthate on the addition of copper sulphate solution.

The presence of carbon bisulphide is a great hindrance to the investigation of the first runnings, for it has the property, in common with several other substances present, of not being changed by concentrated acids and alkalis, for which reason most of the benzene of commerce is contaminated with it.

The following methods of estimating carbon bisulphide may be employed:—

*1st. By means of triethylphosphine.* The carbon bisulphide is dissolved in absolute ether, and an ethereal solution of triethylphosphine added in excess; after a time the liquid becomes red, and deposits small needle-like crystals; after the colour has disappeared, the whole is thrown on to a tared filter, the mother-liquor being used to rinse out the vessel, the crystals finally washed with pure ether, dried in *vacuo* and weighed. Working with pure bisulphide, the author found the results a good deal too low.

*2nd. Estimation as a salt of xanthic acid:—*

The solution containing the carbon bisulphide is added drop by drop to a concentrated solution of caustic potash in absolute alcohol, with constant stirring. The mass of crystals should be thoroughly broken up, and the whole warmed slightly. The xanthate so obtained may be analysed volumetrically either by means of a copper solution or by iodine. For the first process, the copper sulphate solution should be of decimal strength, each cc. of which represents 0.03202 grm. xanthate or 0.0152 grm.  $\text{CS}_2$ . The best method is that of Macagno, who neutralises the solution of the potassium xanthate with acetic acid, and titrates with the copper solution as long as any turbidity is apparent, the end reaction being obtained by testing a drop of the liquid with potassium ferrocyanide. As the cuprous precipitate masks the colour of the copper ferrocyanide, this may be done by putting one drop of the liquid on to a double thickness of filter paper and adding the ferrocyanide to the solution that passes through to the lower layer. Experiments tried by the author on pure  $\text{CS}_2$  gave results 0.54 per cent. too low by this process. Tried on the two crude products mentioned above:—No. 1 gave 19.8 per

cent.  $\text{CS}_2$ , and No. 2, 19.17 per cent.  $\text{CS}_2$ . These figures show that it is impossible to concentrate the carbon bisulphide into one fraction by distillation, and strengthen the idea that it exists in the crude liquid in loose combination with some other substance, which compound is only broken up gradually by boiling.

*The third method of estimation, by means of standard iodine,* depends on the formation of ethyldisulphocarbonic sulphide as discovered by Desains (Annalen [3], **20**, 496). The solution containing the potassium xanthate is exactly neutralised with acetic acid, starch added, and  $\frac{N}{20}$  iodine run in till the blue colour appears. The author's experiments show that this method is far less exact than the former.

The author has tried to estimate carbon bisulphide by converting it into ammonium sulphocyanide by means of alcoholic ammonia: after  $3\frac{1}{2}$  days only, 78.3 per cent. was found to be changed into the sulphocyanide.

He also tried converting the bisulphide into diphenylsulphocarbamide, by warming it with aniline and caustic potash: after several days' heating only 61 per cent. was changed.

To remove the carbon bisulphide from the light "benzole," the best method is to proceed as follows:—1,000 to 1,200 grms. of the fraction are treated with from one-fifth to one-sixth their weight of ordinary alcohol, and to avoid loss of the most volatile portions, put into a freezing mixture. Dry ammonia vapour is then passed through the mixture, care being taken that the leading tube does not become blocked. After a time crystals begin to separate out, and the liquid divides into two distinct layers, the lower consisting of alcohol and water, with the various products of the action on the bisulphide in solution, and containing a small amount of the hydrocarbons, which may be removed by the addition of more water. If the whole liquid is filled with separated solid matter it may be strained through linen, when the division can be easily seen. The top layer should be treated with more alcohol and ammonia passed again, the operation being repeated till crystals no longer separate. The residual liquid is then thoroughly washed with water, dried by means of calcium chloride and distilled.

By this treatment the specific gravity of the fraction No. 1 fell from .8148 to .7401.

The author hopes to continue his researches on the product freed from carbon bisulphide.—F. H. L.

## PATENT.

*Improvements in the Distillation of Mineral Oils and like Products, and Apparatus for that Purpose.* J. Dewar, Cambridge, and B. Redwood, Finchley. Eng. Pat. 13,016, August 17, 1889. *Sd.*

THIS is an apparatus for the distillation of mineral oils under reduced pressure, a current of air or inert gas being passed continuously through the boiling liquid. It consists of a retort, condenser and receiver. The latter is connected with an air-pump and with a second receiver placed beneath it which can also be put into communication with the air pump or with the external air. When a sufficient quantity of the distillate has collected in the first receiver, the two receivers are put into communication and the liquid runs from the first into the second. The communication is now cut off, air is admitted to the second receiver and the distillate run off by a tap at the bottom. A third receiver communicates with the bottom of the retort and serves to withdraw the high-boiling residue. The retort is also furnished with a tube which reaches nearly to the bottom of the retort and serves to admit air or other gas which bubbles through the liquid and assists the distillation.—H. K. T.

## IV.—COLOURING MATTERS AND DYES.

On a Violet Colouring Matter from Illuminating Gas or from the Residues of Gas Purifiers. Jour. f. Gasbeleuchtung, **33**, 304—306.

See under II., page 923.

*The Condensation of Dichlorether with the Cresols.*

C. Brückner. Annalen, **257**, 322—330.

*Ethenyltrieresol.*—The cresols react with dichlorether similarly to the phenols (Ann. **243**, 151, et seq.), ethenyltrieresols being formed according to the equation—

These compounds are prepared by warming a mixture of dichlorether (1 mol.) with cresol (3 mols.) and dropping the solution of the product in glacial acetic acid into a large excess of water. They are white uncrystallisable powders reddened when damp by the air; they are insoluble in water, chloroform, or light petroleum, but dissolve readily in alcohol, ether, glacial acetic acid, ethyl acetate, &c.; on evaporating the solutions they are left in resinous masses. The ortho-compound is soluble in dilute solutions of potash, the meta- and para-compounds only in warm concentrated solutions; they are all reprecipitated unchanged by acids, even by carbonic acid. They do not melt when heated, but form soft resinous masses which become brittle and glassy on cooling. The *o*-compound undergoes this change at 85°, the *m*-compound at 90°, and the *p*-compound only at 100°; at 130° decomposition ensues. The triacetates are pale yellow amorphous powders insoluble in water and in alkalis. When the ethenyltrieresols are boiled for six hours with a little more than a molecular proportion of ferric chloride, and the product is poured into an excess of water, violet-brown flocculent precipitates separate, the alcoholic solution of which directly dye wool and silk violet-brown. The precipitates are purified by repeatedly dissolving them in glacial acetic acid and precipitating with water. By desiccation in vacuo they are obtained as dark powders which may be heated without change to 120°, but decompose at 200°. They are soluble in alcohol, ether, glacial acetic acid, ethyl acetate, acetone, and alkalis, but not in carbon bisulphide, benzene, &c. From aqueous alkaline solutions they are reprecipitated by acids, even by carbonic acid. The constitution of these dyestuffs is slightly different from that of the analogous phenol, naphthol, resorcinol, &c. derivatives, 2 mols. of the corresponding phenol first formed condensing with elimination of water—

The acetates of these dyestuffs are yellow powders which decompose at 100°, the *o*- and *p*-compounds have the composition  $[C(C_7H_6.OC_2H_3O)_2.CH_2(C_7H_6.OC_2H_3O)]_2$ , but the *m*-compound appears to be a mixture of several substances.

—S. B. A. A.

*Hydrazobenzenedisulphonic Acid.* H. Limpricht.

Ber. **23**, 1052—1057.

THE compound formerly known as hydrazobenzenedisulphonic acid has been proved to be benzidinedisulphonic acid. The author has, however, succeeded in preparing the proper hydrazobenzenedisulphonic acid, by heating a mixture of lead azobenzenedisulphonate and water on a water-bath and passing sulphuretted hydrogen through the mixture. On evaporation *m*-amidobenzene sulphonic acid and benzidinedisulphonic acid were precipitated, and finally white needles easily soluble in water were obtained, forming the desired compound. It is a strong reducing agent; mineral acids convert it into benzidinesulphonic

acid and its alkaline solution is changed on evaporation into azobenzenedisulphonic acid.

The barium salt—

forms white or light yellow crystals.

The potash salt,  $C_6H_4(SO_3K)NH.NH(SO_3K)C_6H_4$ , also forms light yellow crystals.—A. L.

*Researches on Azo Derivatives of Phenyl-β-Naphthylamine.* T. Zincke. Ber. **23**, 1314—1325.

BENZENE-AZOPHENYL-β-NAPHTHYLAMINE yields on oxidation with chromic acid the chromic salt of a well characterised ammonium base,  $C_{22}H_{16}N_4.OH$ , which, on careful reduction reproduces benzene-azophenyl-β-naphthylamine. If the aqueous solution of this compound be heated on the water-bath a red resinous matter is gradually precipitated, whilst the bitter taste of the solution decreases in intensity. On treatment with alcohol a base is dissolved from the resin, and the residue consists of benzene-azo-β-naphthylphenylamine. The same reactions take place if the chloride of the base is heated with caustic potash. The alcoholic solution precipitates on dilution with water a body of the formula  $C_{22}H_{16}N_4O$ , which, after crystallisation from benzene, forms yellowish needles, melting at 215°—217° C. It is easily soluble in alcohol, glacial acetic acid, and benzene, and shows strong greenish fluorescence especially in dilute solutions. It forms salts. The author discusses at great length the constitution of the base obtained from the azo compound, without however arriving at a final conclusion as to its constitution.

—A. L.

*Azo Derivatives of Secondary-β-Naphthylamine Derivatives, and their Oxidation Products.* P. Matthes. Ber. **23**, 1325—1334.

*p-Toluene-azo-β-naphthylphenylamine*, prepared from β-naphthylphenylamine and *p*-diazotoluene chloride, forms, after crystallisation from alcohol, dark red needles of a beautiful metallic lustre, easily soluble in benzene, less in alcohol and glacial acetic acid. Melting point = 120° C.

*Ammonium Base from p-Toluene-azo-β-naphthylphenylamine.*—The azo-compound is dissolved in 10 times its weight of hot glacial acetic acid. The solution is then cooled to 40°—45° C., and a hot concentrated solution of potassium bichromate is gradually added until the liquid becomes brown and yields, on dilution with water, a yellow precipitate, the chromic salt of the new base. The nitrate, picrate, the platinum, mercury, and tin double salts are described.

*Benzene-azo-β-naphthyltolylamine*—

forms long dark red needles easily soluble in hot glacial acetic acid and benzene, with more difficulty in alcohol and ether, melting at 152° C. It yields on oxidation an ammonium base, of which several salts are described.

*Benzene-azo-α-β-dinaphthylamine*—

Two isomerides are formed. The β-compound obtained by crystallisation from benzene forms red needles, melting at 167° C. On boiling with alcohol in hydrochloric acid, Witt's asymmetrical azine was obtained, melting at 283°—284° C. On carefully oxidising the azo-compound, the ammonium base was obtained, of which several salts are described.

*α-Naphthalene-azo-β-naphthylphenylamine*—

forms dark red needles, melting at 140° C., with difficulty soluble in alcohol, more easily in benzene and glacial acetic acid. The ammonium base is prepared by oxidising the azo-compound with chromic acid.

*β-Naphthalene-azo-β-naphthylphenylamine—*

forms long brick-red needles, melting at 154°–155° C. On oxidation with chromic acid the ammonium base is obtained.

*Benzene-azo-β-β-dinaphthylamine—*

is only formed if the solutions are kept very cold and if the diazo solution does not contain an excess of free acid. Red needles, melting at 139° C.

*Symmetrical-β-β-naphthazine—*

is obtained if a strongly acid solution of diazobenzene chloride is added to a warm solution of β-β-dinaphthylamine. It forms yellowish needles, melting at 242°–243° C., and showing blue fluorescence in benzene and green fluorescence in acetic acid.—A. L.

*The Formation of Colouring Matters from Tetrahydroquinoline.* E. Lellmann and H. Boye. Ber. **23**, 1374–1383.

*p-AMIDOPHENYLPYPERIDINE—*

shows the same colour reactions as *p*-amidodimethylaniline. Tetrahydroquinoline can be considered as a mono-ethyl-orthotoluidine, in which the two alkyl groups are joined together—

This supposition originated the idea of submitting the tetrahydroquinoline to some tests which, when applied to dimethylaniline, produced colouring matters; the result proved the theory to be correct.

If a cold solution of equal molecular proportions of tetrahydroquinoline hydrochloride and amidodimethylaniline hydrochloride are oxidised with the theoretical quantity of potassium bichromate, an intensely green solution is obtained, which contains an indamine of the formula—

the same product is formed by gently heating aqueous solutions of nitrosodimethylaniline hydrochloride and tetrahydroquinoline hydrochloride. This indamine, which shows all the characteristic reactions with acids and alkalis has, however, some characteristic properties, being converted by intramolecular reduction into a leuco base. If its solution is allowed to stand or is gently heated, the green colour disappears gradually, and after 1–2 hours a colourless solution is formed.

The authors explain this reaction by the following formulae:—

On addition of potassium bichromate to a solution of the leuco base the solution is again coloured green, but of a more brownish tint than the original solution. It probably contains an indamine of the following constitution:—

But its solution is again soon decolourised, and probably a body formed of the constitution—

If molecular quantities of amidodimethylanilinesulphonic acid and tetrahydroquinoline hydrochloride are oxidised with potassium bichromate, the indamine of the sulphonic acid settles down in small green needles of metallic lustre, with difficulty soluble in water. They cannot be recrystallised without decomposition. The reaction takes place according to the equation—

$\text{C}_9\text{H}_{11}\text{N} + \text{C}_8\text{H}_{12}\text{O}_3\text{N}_2\text{S}_2 + \text{O}_5 = \text{C}_{17}\text{H}_{19}\text{O}_3\text{S}_2\text{N}_3 + 2 \text{H}_2\text{O}$ ,  
and the new compound, the indamine of *Tetrahydroquinolinedimethylanilinesulphonic acid* has probably the constitution—

On standing this compound is converted into a leuco base, probably—

On reducing the tetrahydro-indamine with zinc dust and hydrochloric acid, sulphuretted hydrogen is evolved, and the solution precipitates on addition of ferric chloride an abundant quantity of a blue colouring matter, which, according to its formation and properties, belongs to the class of the thionines and is analogous to Methylene blue. Its formula ought to be—

Tetramethylindaminesulphonic acid produces on boiling with water leucomethylene blue. When the leuco base of the dihydro-indamine is treated in the same manner for a day the sulphite of a new leuco base is formed, which on oxidation with ferric chloride produces a new blue colouring matter—

differing in shade and intensity from the Tetrahydro blue.

Kairolin or methyltetrahydroquinoline is also capable of forming indamines and blue colouring matters.—A. L.

*On some Piperidine Bases.* E. Lellmann and H. Büttner. Ber. **23**, 1383–1388.

AROMATIC halogen compounds act on piperidine at a high temperature; bromobenzene, for instance, produces with piperidine at 250° C. *Phenylpiperidine*. The authors have prepared—

*Tertiary-α-naphthylpiperidine*,  $\text{C}_{10}\text{H}_7\text{NC}_5\text{H}_{10}$ , oil, boiling at 185°–190° C.

*Tertiary-β-naphthylpiperidine*,  $C_{10}H_7NC_5H_{10}$ , crystals, melting at  $57^{\circ}$ — $58^{\circ}$  C.

*Tertiary anthracylpiperidine*,  $C_{14}H_9NC_5H_{10}$ , yellow needles.

*Tertiary phenanthrylpiperidine*,  $C_{14}H_9NC_5H_{10}$ , crystals, melting at  $113^{\circ}$  C.

*p-Nitro-α-naphthylpiperidine*,  $NO_2C_{10}H_6NC_5H_{10}$ , yellow needles melting at  $17^{\circ}$  C.

#### Piperidylhydramine—

obtained by acting with 6 molecules of piperidine on fluorescein chloride at  $220^{\circ}$  C. The contents of the tube were heated with alcohol and hydrochloric acid. The solution was evaporated to dryness and the residue dissolved in dilute hydrochloric acid. Alkalis precipitate the rhodamine base as a violet floccular precipitate, easily soluble in alcohol and very stable towards alkalis.—A. L.

*On Paramidotriphenylcarbinol*. A. Baeyer and R. Löhr. Ber. 23, 1621—1628.

*Paranitrotriphenylmethane*,  $C_{19}H_{15}NO_2$ , is obtained by allowing a mixture of 5 grms. of *p*-nitrobenzaldehyde, 20 grms. of benzene, and 20 grms. of sulphuric acid to stand for 24 hours. The benzene solution is then washed with sodium carbonate, sodium bisulphite, and water; the excess of benzene is evaporated, and the condensation product is obtained as a thick oil, crystallising after some time. After repeated crystallisations from petroleum spirit it is obtained in beautiful colourless crystals, melting at  $93^{\circ}$  C. On treatment with fuming nitric acid it is converted into *Triparanitrotriphenylmethane*.

*Paranitrotriphenylcarbinol* is prepared from the hydrocarbon by oxidation with chromic acid. The hydrocarbon is dissolved in glacial acetic acid, and 4—5 times its weight of chromic acid are added, until a sample poured into water separates in crystals. The hydrocarbon is removed by petroleum spirit and the carbinol purified by dissolving it in glacial acetic acid by precipitation with water. It melts at  $136^{\circ}$  C.

*Paramidotriphenylmethane* was obtained from the nitro-compound by heating it on the water-bath for several hours with tin and hydrochloric acid until the solution became colourless. The free base, when crystallised from benzene, contains benzene of crystallisation, and forms large prisms of the formula  $C_{19}H_{15}NH_2 + C_6H_6$ . The body is soluble in ether, alcohol, and petroleum spirit, and melts at  $83^{\circ}$ — $84^{\circ}$  C.

Its *Acetyl-compound*,  $(C_6H_5)_2CHC_6H_4NH(C_2H_5O)$ , forms needles or prisms melting at  $157^{\circ}$  C. This compound yields, when carefully oxidised with chromic acid in a solution of glacial acetic acid, *Acetylparamidotriphenylcarbinol*  $(C_6H_5)_2C(OH)C_6H_4NH(C_2H_5O)$ , soluble in glacial acetic acid and alcohol, and melting at  $176^{\circ}$  C. On saponification of this product with hot dilute sulphuric acid the sulphate of *paramidotriphenylcarbinol* is obtained as a dark red solution. The hydrochloride forms also a red salt, crystallising in long red needles. The free base is colourless, soluble in ether, alcohol, and benzene, and crystallising from toluene or a mixture of ether and petroleum spirit in small colourless crystals melting at  $116^{\circ}$  C.

On reducing *paranitrotriphenylcarbinol*, *amidobenzophenone*,  $C_6H_5COC_6H_4NH_2$ , melting at  $123^{\circ}$ — $124^{\circ}$  C., is formed.

*p-Monamidotriphenylcarbinol* forms red coloured salts, but they have no affinity for animal fibre.—A. L.

*On a Molecular Interchange between a Diazo and a Phenolic Group*. E. Lellmann and H. Boye. Ber. 23, 1781—1783.

ALCOHOLIC solutions of 1 mol. of orthonitrobenzylchloride and 2 mol. of ethylmeta-amidophenol are heated on the water-bath, the alcohol distilled off, and the dark, viscous oil which remains extracted repeatedly with water, to remove the hydrochloride of ethylamidophenol. On treating the residue with dilute hydrochloric acid, it gradually changes to a light grey powder, which the authors assume to be the hydrochloride of orthonitrobenzylethylmeta-amidophenol. This substance was reduced with stannous chloride, and after diluting the solution was poured into ammonium sulphide, when the corresponding amido compound separated out. This was dissolved in dilute hydrochloric acid and treated with 1 mol. of sodium nitrite. A brown colour was produced, which after some time was precipitated from its solution with sodium acetate. Its formula is  $C_{15}H_{15}ON_3$ , and the formation of the dye may be interpreted by assuming that the diazo-chloride of orthoamidobenzylethylmeta-amidophenol is first formed, which then is converted into the azo-dye by the elimination of hydrochloric acid.

The new dye, which can also be regarded as azobenzyl-ethylamidophenol, dyes silk a yellowish-brown shade which is hardly altered by acids or alkalis.—A. R.

*Orthonitrodiphenylamine and some of its Derivatives*. M. Schöpf. Ber. 23, 1839—1844.

THE best method of preparing this body is to act on orthobromonitrobenzene with an excess of aniline. It is impossible to prevent the formation of coloured by-products. To obtain a fair yield, the substances should be allowed to react for three hours, and then be poured into water. After acidifying with hydrochloric acid, the bromonitrobenzene which has not been attacked is distilled over with steam. On now cooling, orthonitrodiphenylamine separates out and may be crystallised from weak alcohol. Orange-coloured leaflets are obtained, melting at  $75^{\circ}$ . A description of the preparation of orthonitrodiphenylparatolylamine is also given. *Phenylorthophenylenediamine* is readily prepared by heating nitrodiphenylamine to  $120^{\circ}$  with alcoholic sulphide of ammonium. After evaporating most of the alcohol, the residue is treated with hydrochloric acid, boiled to separate out the sulphur, then cleared with some animal charcoal and the base precipitated with ammonia. After recrystallising from alcohol with addition of animal charcoal, needles melting at  $79^{\circ}$ — $80^{\circ}$  are obtained. The amine is soluble in much hot water. A solution of the hydrochloride is coloured deep red by ferric chloride, and a brown precipitate is produced, which, if the solution be dilute, is deposited in the shape of brown needles, with green reflex; this body probably belongs to the group of the azines.

On adding sodium nitrate to a solution of phenylphenylenediamine in dilute hydrochloric acid, *phenylazimidobenzene* is obtained. It is recrystallised from weak alcohol, when reddish needles, melting at  $89^{\circ}$ — $90^{\circ}$ , separate out.

A by-product obtained in the manufacture of amidoazobenzene has been described by Gattermann and Wichmann, which yields aniline and orthophenylenediamine on reduction; they have therefore assigned to that substance the formula—

which would be identical with that of phenylazimidobenzene. Now, the latest researches of Zincke and Campbell point to the existence of two series of these imido-compounds. That class which they distinguish by the term pseudo-azimides is produced by oxidation of orthoamidoazo bodies, the other azimides result from the action of nitrous acid on orthodiamines. The by-product of amidoazobenzene is evidently the pseudoazimide. It differs from the one described by the author of this paper in melting 20° higher. —A. R.

*Derivatives of Diphenylamine and of Phenazine.* R. Nietzki and O. Ernst. Ber. **23**, 1852—1856.

This research was undertaken with a view to preparing the simplest analogue to Toluylene-blue, viz., triamidodiphenylamine—

By the interaction of molecular proportions of dinitrochlorobenzene and paraphenylenediamine in alcoholic solution, amidodinitrodiphenylamine is obtained in quantitative yield, the equivalent quantity of sodium acetate being added after the reaction is complete. The new body is with difficulty soluble in hot alcohol, more readily in benzene or chloroform, from which it crystallises in lustrous brown leaflets melting at 177°. It dissolves in hot fairly concentrated hydrochloric acid. On cooling, the hydrochloride crystallises out. The pieric acid additive compound, as well as the mono- and diacetyl derivatives are also described.

On reducing with stannous chloride and hydrochloric acid, triamidodiphenylamine is readily formed and may be separated as the stannio-chloride by passing hydrochloric acid gas into the solution. The hydrochloride of the base is rapidly oxidised in the air, the sulphate being somewhat more stable. Triamidodiphenylamine is the leuco base of the simplest analogue to toluylene-blue. On oxidation it yields a violet-blue dye which shows the characteristic properties of the dyes of this group, but is much less stable than Toluylene-blue.

For preparing the azine, 20 grms. of the stannio-chloride compound of triamidodiphenylamine are dissolved in half a litre of water, 12 grms. of calcium carbonate added, and then 20 grms. of manganese dioxide (about 60 per cent. strength). The mixture is gradually heated on the water-bath and then boiled until it is coloured yellowish-brown and a drop on blotting paper is no longer coloured violet on the border. The solution is now filtered, a few drops of hydrochloric acid added, and the dyestuff salted out. The crude hydrochloride may be dissolved in boiling water. By adding ammonia while hot, the base crystallises on cooling in long dark yellow needles melting at 280°, readily soluble in alcohol or ether to yellow solutions which exhibit strong fluorescence. The formula of the new azine is—

Concentrated sulphuric acid dissolves the base with a green colour which on diluting changes from blue and violet to red. The pierate, platino-chloride and diacetyl derivative were also prepared. In dilute acids the base dissolves with a red colour. The salts crystallise well. They dye silk and tannin-mordanted cotton red, much yellower than the simplest safranines, more like scarlets. By alkalis the red is very easily changed to yellow.

Diamidophenazine may also be obtained by joint oxidation of para- and metaphenylenediamine or by boiling the latter with quinone-dichlorimide in alcoholic solution.

The connexion of the new azine with phenazine was proved by splitting off the amido group in the usual manner. The resulting body was in every way identical with Claus and Riz's phenazine.—A. R.

*On some Azo-Dyes from α-Naphthylamine, Dimethylaniline, and α-Hydroxynaphthoic Acid.* C. A. Bischoff. Ber. **23**, 1908—1911.

*Dimethylamidobenzene-α-azonaphthalene—*

is prepared by diazotising a salt of α-naphthylamine, filtering, and combining with dimethylaniline in alcoholic solution. The dye is purified by treatment with hot dilute acid and then with ammonia. It is quite insoluble in water. From a solution in acetone prismatic crystals were obtained which appear black in reflected and red in transmitted light. For dyeing, the azo-compound was sulphonated with acid containing 20½ per cent. anhydride. According to the degree of sulphonation, the sodium salts of the resulting acids dyed silk and wool yellow, orange, or brown.

*α-Naphthylazo-α-hydroxynaphthoic acid—*

is best prepared by allowing a cold solution of α-diazo-naphthalene chloride to flow in a thin stream into a well-cooled solution of α-hydroxynaphthoic acid in sodium carbonate. The dye which separates is washed, dried at 100°, and crystallised from glacial acetic acid. A very good yield of leaflets of gold-like lustre are obtained, melting at 198°. The new acid is sparingly soluble in boiling water and the usual solvents except glacial acetic acid and chloroform, in which it dissolves readily. Concentrated sulphuric acid gives a blue solution and green flakes appear on adding water. Alkalis give two series of salts; the neutral ones are deep red and very soluble, the acid salts dissolve with greater difficulty in cold water and they are coloured yellow. The latter do not dye unmordanted cotton. Wool was treated with warm dilute acetic acid after dyeing. It is coloured a brilliant orange yellow. The shades on silk are not fast to soap.

Below are given some of the more recently discovered yellow dyes, commencing with the greenest and passing from the orange to the brown dyes. Quinoline-yellow, Auramine, Carbazol-yellow, Primuline, Piazzine-yellow, Tartrazine; Brilliant yellow, Helianthine, Metanil-yellow; Bronstein's orange, Jacobsohn's orange I., Brown II. and III.

The most unstable to light are, Carbazol-yellow, Piazzine-yellow (from diphenyl piperazine and sulphanilic acid) and Primuline-yellow.

On moistening with concentrated hydrochloric acid, Auramine becomes light violet; Quinoline-yellow a slight brownish-yellow; Carbazol-yellow at first green then a black-violet; Primuline orange; Piazzine-yellow carmine; Tartrazine is hardly changed; Brilliant yellow turns a deep violet; Helianthine violet-blue; Metanil-yellow a deep blue-violet; Bronstein's orange is first coloured greenish then a slight brown; Jacobsohn's orange I. carmine, Brown II. and III. violet. All these tests refer to the colours on wool.

—A. R.

*On the Sulphonation of Aniline and Naphthylamine with Acid Potassium Sulphate.* C. A. Bischoff. Ber. **23**, 1912—1914.

ANILINE or α-naphthylamine and about triple the quantity of acid potassium sulphate are intimately mixed and heated in an oil-bath to 200°. The yield of sulphanilic or of naphthionic acid in the best cases did not exceed 19 per cent., calculated on the base originally used. In the case of β-naphthylamine as much as 86 per cent. sulphonie acid was obtained.

Much better yields of sulphanilic or of naphthionic acid were obtained by the so-called "baking" process. After intimately mixing base and acid sulphate in the above proportions the mass was cut up into thin cakes, these were allowed to soften at 60—80°, pressed with hot plates, and then heated for three hours to 200°; a 50 per cent. yield of the sulphonated product was obtained in this case. From α-naphthylamine α-naphthionic acid is produced, β-naphthylamine gives β₁-β₂-naphthionic acid with traces of β-naphthylamine sulphonie acid. The results therefore are identical (apart from the yield) with the ordinary process of heating the acid sulphates of the respective bases.—A. R.

*On the Composition of Diphenyl- and Phenyl-naphthylamine-Blue.* A. Hausdörfer. Ber. **23**, 1961—1966.

THOUGH it has always been assumed that diphenylamine-blue and triphenylrosaniline-blue are identical in composition, analytical proofs have not yet been forthcoming, and this research was mainly undertaken to establish the above fact on a firmer basis. Diphenylamine-blue was prepared by Schoop's method, which consists in heating diphenylamine to 110° and gradually adding double its weight of crystallised oxalic acid. The temperature is kept for eight hours at 130°—132°. Oxalic acid is now removed from the melt with hot water, the residue extracted with alcohol and the requisite quantity of concentrated hydrochloric acid added. The hydrochloride, which separates after 12 hours' standing, is repeatedly boiled with alcohol and finally converted into the base with alcoholic caustic soda. After filtering, the hydrochloride is re-precipitated with hydrochloric acid. The dye possesses the same properties as triphenylrosaniline-blue and an analysis gave figures which correspond to the composition of the latter body. The identity of this blue with the one prepared in the above manner is now placed beyond all doubt.

*Phenyl- $\alpha$ -naphthylamine-blue* was prepared in the same manner as the previously described dye, only substituting phenyl- $\alpha$ -naphthylamine for diphenylamine. In this case, however, the blue-base is almost insoluble in alcohol. After extracting with water and alcohol the base is precipitated with alcoholic soda, dissolved in acetone and the dye precipitated with concentrated hydrochloric acid. It is with difficulty soluble in the usual solvents, and dissolves best in warm aniline. Its properties resemble those of triphenylrosaniline blue, and its formula is proved by analysis to be  $\text{CCl}(\text{C}_6\text{H}_4\text{NHC}_{10}\text{H}_7)_3$ .—A. R.

*On Cyanamides, a New Group of Dyes.* O. N. Witt. Ber. **23**, 2247—2252.

By the action of  $\beta$ -naphthol on the hydrochloride of nitrosodimethylaniline, Meldola obtained a bluish-violet cotton-dye in 1879, which has been manufactured on an industrial scale since 1883, and is known as New-blue, Fast-blue, Cotton-blue, &c. Another dye was prepared by Nietzki by the action of  $\beta$ -naphthol on quinonedichlorimide. The formulae of these two dyes most probably are—

The various products in the market known as New-blue differ considerably in their solubility, and the shade with which they dye. Apart from intentional additions, different samples of New-blue will dye from bluish-violet to violet-red shades, and this must be set down to the product being actually a mixture of different dyes. Nietzki's dye, however, prepared from quinonedichlorimide, appears to be a uniform product dyeing a magenta-red.

One property which all New-blues possess is that they are "*day blues*," i.e. with artificial light the blue caste seems to give way to a red one; in fact the products of different makers when dyed on cotton and examined in yellow light all appeared reddish-brown.

Now by the action of alkalis these dyes undergo a remarkable change. Their bases, at first readily soluble in ether, become more and more insoluble the further the action of the alkali is allowed to proceed. On dissolving the base in acid again, dyes of a pure greenish-blue shade

are obtained which resemble Methylene blue. They are night-blues, i.e. their shade is hardly changed by gas-light. The dye prepared in this manner from Meldola's violet does not differ from the one prepared in a similar manner from Nietzki's red.

The new dyes have been named *Cyanamides* by the author. The following is a method of preparation which gives good results: 56 grms.  $\beta$ -naphthol are heated on the water-bath with 74 grms. nitrosodimethylaniline hydrochloride and 160 cc. alcohol, until the violent reaction at first ensuing has ceased. 40 grms. caustic potash in 240 cc. alcohol are now added and the mixture heated until it becomes more fluid and crystals begin to separate out. The crystals are filtered off hot, washed with alcohol and water, again boiled with alcohol and filtered. The base is finally dissolved in dilute acid, filtered from a small quantity of an insoluble violet by-product and reprecipitated with ammonia. The base is best recrystallised from chloroform. In alcohol, ether, or benzene it is almost insoluble. The solutions are coloured a pure violet-red, whereas solutions of the base of New-blue are coloured reddish-brown. Concentrated acids dissolve the latter with a green colour, whilst the new base forms brownish-orange solutions. By dissolving in dilute acids, the blue coloured salts are obtained; they separate from their solutions in lustrous tarry masses, which become hard on drying. From alcoholic solutions the salts may be obtained in the crystalline form. Dilute aqueous solutions of the chloride or sulphate gelatinise on cooling. If the former be very dilute the salts are partially dissociated, basic insoluble salts separating out. One portion of the acid in the molecule is therefore bound more intimately than the other.

The Cyanamide salts are distinguished by a special absorption spectrum, even in very dilute solutions. The entire spectrum from red to green is extinguished, leaving the other part unaffected. Now since the different kinds of New-blue have practically no effect whatever on the yellow or red portion of the spectrum, this proves that even the bluer shades of certain specimens of that dye are not due to an admixture of Cyanamide.

In attempting to apply the results of an analysis of the hydrochloride and of the base to the construction of formulae for these new compounds the author was led to conclude that this is only possible by assuming that 2 mols. of nitrosodimethylaniline react with 1 mol. of naphthol, whence the following probable formula for base and hydrochloride, respectively—

By oxidation with chromic acid Cyanamide-blue is converted into violet-blue dyes which show a brilliant cinnabar-red fluorescence.—A. R.

*On the Constitution of Eurhodines, Indulines and Related Dyes.* F. Kehrmann. Ber. **23**, 2446—2454.

WHILE it is not astonishing that azines are produced from orthotolylendiamine and rhodizonic acid, which is an orthoquinone, the same cannot be said with regard to the similar reaction which takes place between the diamine and tetrahydroxyquinone, doubtless a paraquinone. The author believes the reaction in the latter case is best explained by assuming that one quinone-oxygen atom and the adjoining hydroxyl-group react with the amido-groups—

It appears that other hydroxy-para-quinones are also able to react in a similar manner with orthodiamines; this however is restricted to those paraquinones that do not contain in the hydrocarbon nucleus radicles with a high molecular weight. Thus chloraniline and nitraniline acid do not give azine derivatives, but very stable diamine salts of the hydroxyquinones.

The toluylene-azine of tetrahydroxyquinone is the only one that has hitherto been described. The corresponding phenylene compound was prepared by the author by acting with one molecule of the sodium salt of tetrahydroxyquinone on one molecule of a phenylenediamine salt in dilute aqueous solution. On acidifying with acetic acid greenish-brown needles separate out, which when damp oxidise rapidly in the air; this azine crystallises more readily than the corresponding toluylene-azine, it dissolves with a dark olive-green colour in dilute mineral acids and is oxidised to the rhodizonic derivative by dissolving in fixed alkalis, a violet-blue colouration appearing at the same time. The azine from chloroparadihydroxyquinone is also described. This new body dissolves in alkalis or alkaline carbonates with a reddish-yellow colour almost identical with the colour of alcoholic solutions of O. Fischer and Hepp's diamidophenazine.

By the action of hydroxynaphthoquinone-isoide on orthophenylenediamine,  $\alpha$ -amidonaphthophenazine, described by Fischer and Hepp, is produced. Dihydroxyphenazine, which has also been prepared by these authors, is probably identical with the condensation product of dihydroxyquinone and phenylenediamine.

For preparing  $\alpha$ -naphtho-eurhodol one molecule of the sodium salt of hydroxynaphthoquinone is dissolved in boiling water, acidified with acetic acid, and treated with one molecule of phenylenediamine sulphate. The mass is finally heated on the water-bath, filtered, dissolved in hot but very weak caustic soda, again filtered and the blood-red filtrate precipitated with quarter of its volume of concentrated caustic soda solution. The golden-yellow metallic leaflets of the sodium salt which separate are filtered, dissolved in water and the eurhodol precipitated with acetic acid. The latter is at once crystallised from boiling acetic acid. The crystals that separate are now almost insoluble in acetic acid. This product is identical with the one prepared by converting Fischer and Hepp's amidonaphthophenazine into the corresponding eurhodol.

By replacing phenylenediamine with orthodiamidotoluene (1:2:4) in the above mentioned case, the eurhodol which corresponds to the eurhodine-base C<sub>17</sub>H<sub>13</sub>N<sub>3</sub> is obtained; the latter was first prepared by Witt from orthoamidoazotoluene and  $\alpha$ -naphthylamine.—A. R.

# PATENTS.

*Improvements in Producing Yellow Colouring Matter suitable for Dyeing and Printing.* W. W. Grieve, Glasgow. From "The Farbenfabriken vormals F. Bayer & Co.," Elberfeld, Germany. Eng. Pat. 9606, July 1, 1884. Amended March 27, 1890. 4d.

THE original specification has already been abstracted (this Journal, 1885, 491). In the amended specification the claim is confined to the production of a yellow dyestuff by the action of tetrazo-ditolyl on salicylic acid. (See also this Journal, 1885, 400, and 1890, 497.)—T. A. L.

*Improvements in the Preparation of a Beta-Naphthylamine Sulphonic Acid and of Colouring Matters therefrom.* A. G. Green, London. Eng. Pat. 15,849, November 2, 1888. Reprint. 4d.

ALREADY abstracted (this Journal, 1889, 878). The Comptroller's amendment is as follows:—"I (the patentee) am aware of the specification of Letters Patent 5846 of 1886 (this Journal, 1887, 436) granted to J. Y. Johnson, and I wish it to be understood that I do not claim anything described and claimed therein." A further amendment is the insertion of the word "when" in claim 3.—T. A. L.

*Manufacture of Colouring Matters Derived from Para-Toluidine,  $\alpha$ -Metylglidine, Pseudocumidine and Mesidine with Tetramethyldiamido Benzhydrol.* O. Imray, London. From "La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis," Paris, France. Eng. Pat. 12,784, August 13, 1889. 6d.

A METHOD for obtaining triphenylmethane derivatives which dye green to blue shades by condensing *p*-toluidine,  $\alpha$ -metylglidine,  $\psi$ -cumidine or mesidine, with tetramethyldiamidobenzhydrol by means of sulphuric acid or hydrochloric acid. The leuco bases thus obtained are oxidised with lead peroxide, yielding dyestuffs which may be diazotised and converted into hydroxy-derivatives. Previous to oxidation the leuco bases may, as an alternative, be benzylated and sulphonated when greenish-blue colouring matters are obtained. These dyestuffs are said to possess a great affinity for wool which is easily dyed in an acid bath.

—T. A. L.

*Improvements in the Manufacture of Colouring Matters.* H. H. Lake, London. From A. Leonhardt and Co., Mühlheim, Germany. Eng. Pat. 13,217, August 21, 1889. 6d.

By acting with formaldehyde on dimethyl- or diethyl-*m*-amidophenol colourless condensation products are formed, namely, tetramethyl- or tetra-ethyl-diamidodihydroxydiphenylmethane. On treatment with a dehydrating agent these products undergo a further condensation according to the general equation:—

These substances on oxidation yield pink dyestuffs which may be employed for dyeing or printing on cotton. The following is one of the methods given for obtaining a colouring matter from dimethyl-*m*-amidophenol. A solution of 28 kilos. of dimethyl-*m*-amidophenol in 200 litres of 60 per cent. alcohol is treated with 10 kilos. of a 30 per cent. aqueous solution of formaldehyde. After standing some time the condensation product separates out in small plates melting at 180° C.; 10 kilos. of this are heated to about 100° C. with 50 kilos. of ordinary sulphuric acid until a sample dissolved in water, neutralised with caustic soda and filtered, does not give any precipitate when acetic acid

is added to the filtrate. The whole melt is then poured into water and the tetramethyldiamidodiphenylmethane oxide precipitated with caustic soda. In order to oxidise it, 2·7 kilos. are dissolved in 120 litres of water, 4 kilos. of hydrochloric acid added and when cold a solution of about 0·8 kilos. of sodium nitrite is run in. The colouring matter obtained is precipitated with zinc chloride and common salt.—T. A. L.

*Improvements in Producing Azo-Colours on or in Cotton or other Textile Fibre or Fabrics.* T. Holliday, Huddersfield. Eng. Pat. 16,156, October 14, 1889. 6d.

See under VI., page 939.

*Manufacture of a Grey Basic Colouring Matter Soluble in Water.* J. Dawson, Huddersfield. Eng. Pat. 16,448, October 18, 1889. 6d.

WHEN amidodimethylaniline is oxidised with chromic acid in presence of one molecule of hydrochloric acid or under certain other conditions, it is converted into two basic colouring matters, one blue and easily soluble, the other greyish-violet and less soluble in water.\* The following proportions are given: 10 kilos. of nitrosodimethylaniline hydrochloride are suspended in 700 litres of water and reduced with 10 kilos. of zinc dust at 40°. When decolourised the solution is neutralised with soda ash, filtered, and 7 kilos. of 30 per cent. hydrochloric acid or 5·8 kilos. of sulphuric acid or 4 kilos. of zinc chloride added; 5 kilos. of potassium bichromate and 4·5 kilos. of hydrochloric acid, or 3·6 kilos. of sulphuric acid, or 2·5 kilos. of zinc chloride in 100 litres of water are then added to the boiling solution. When the oxidation is complete the solution is filtered hot, and the blue colouring matter precipitated cold by the addition of 2·5 kilos. of zinc chloride and 100 kilos. of salt. The residue containing chromium left after filtering the hot solution is suspended in 400 litres of water and boiled with 5 kilos. of hydrochloric acid. After filtering, a greyish-violet colouring matter is precipitated by the addition of zinc chloride and salt. The blue colouring matter is a dark blue powder dissolving in sulphuric acid with a green colour. It is easily soluble in alcohol and water, and dyes cotton blue with a tannin- and black with an iron-mordant. The base is supposed to have the following formula:—

The greyish-violet colouring matter is "only perfectly soluble in acidulated water," and dissolves in sulphuric acid with a dirty brown colour. Cotton mordanted with tannin is dyed a greyish-violet, and it can also be used with unmordanted cotton.—T. A. L.

*The Preparation of Amidonaphtholsulphonic Acid, and of Colouring Matters therefrom.* S. Pitt, London. From L. Casella and Co., Frankfort-on-the-Maine, Germany. Eng. Pat. 16,699, October 22, 1889. 6d.

By fusing the  $\beta$ -naphthylamine- $\gamma$ -disulphonic acid, described in Eng. Pat. 816 of 1884 (this Journal, 1884, 567) with caustic soda at a temperature not exceeding 200° C., an amidonaphtholmonosulphonic acid is obtained, which combines with diazo compounds to form dyestuffs. The combination can take place in an acid or alkaline solution, and in the latter case the resultant compound can be rediazotised and again combined with amines or phenols. The colouring matters obtained are reds, browns, and violet-blues, and are said to be fast to milling and scouring. The amidonaphtholsulphonic acid itself appears to form a diazo compound of a yellow colour scarcely soluble in

water. This forms azo colours with amines and phenols, and by the action of an alkali it is converted into a violet colouring matter.—T. A. L.

*An Improved Manufacture of Colouring Matter.* H. H. Lake, London. From A. Leonhardt and Co., Muhlheim, Germany. Eng. Pat. 17,223, October 30, 1889. 4d.

A PROCESS for obtaining a nitrosodihydroxynaphthalene from the dihydroxynaphthalene melting at 186° C. by adding sodium nitrite to its solution in dilute sulphuric acid. The reddish-brown precipitate of the nitroso compound which is formed, gives coloured lakes with metallic oxides, that with iron being green, and on wool fast to light and fulling. With a chromium mordant the shades are brown. The colours are of no value for dyeing cotton.

—T. A. L.

*Improvements relating to Colouring Matters.* H. H. Lake, London. From A. Leonhardt and Co., Muhlheim, Germany. Eng. Pat. 17,971, November 11, 1889. 4d.

By condensing formaldehyde with *m*-toluylendiamine a tetra-amido derivative of diphenylmethane is obtained, which by elimination of ammonia and subsequent oxidation yields a yellow dyestuff. The following method is employed for its preparation: 13 kilos. of *m*-toluylendiamine and 26 kilos. of its sulphate are dissolved in 200 litres of water and treated when cold with 10 kilos. of a 30 per cent. solution of formaldehyde. After standing a short time the sulphate of the condensation product separates and may be filtered off. 10 kilos. of this are then heated in an enamelled autoclave with 30 kilos. of hydrochloric acid (containing 30 per cent. HCl) and 100 litres of water for six hours to 160° C. The brownish-red liquid thus obtained is filtered if necessary, and oxidised with 10 litres of a solution of ferric chloride of sp. gr. 1·4 and heated to about 90°. The colouring matter separates as a yellow crystalline powder which is filtered off and washed with dilute hydrochloric acid or brine. It dyes mordanted cotton yellow, and is faster to soap than benzoflavine. On silk or in an aqueous or alcoholic solution it shows a green fluorescence.—T. A. L.

## V.—TEXTILES: COTTON, WOOL, SILK, Etc.

*Shoddy.* J. Herzfeld. Chem. Zeit. 14, 903—904.

THE title "Shoddy" is intended to apply to all artificially recovered wool, although there is no exact English equivalent to the German "Kunstwolle," which includes all the recovered material from mungo shoddy and "extract," or wool from mixed goods. The industry was introduced from England into Germany by Gustav Kober in 1851 at Cologne, and after some early struggles flourished at Mannheim, spreading thence to all parts. To Kober is due the method of separating woollen from vegetable fibres by treatment with sulphuric acid. In such a manufacture the collection, sorting, and cleaning of the raw material are of much importance, but present little technical interest. The separation of vegetable fibres calls, however, for a more detailed account. Two processes are in use, the wet and the dry; in the former the raw material is soaked in sulphuric acid of 4°—7° B. for 12 hours, the greater part of the acid removed from it in a centrifugal machine and dried at 40°—50° C., after which it is carbonised at 90°—95° C. In the latter it is treated with gaseous hydrochloric acid. In either case the carbonised vegetable fibre is beaten out. The recovered wool felts badly.

It is estimated that at least 100—150 million kilos. of recovered wool are produced yearly in Europe. Ten years ago only 34 per cent. of the cloth made in England was prepared from pure new wool, and 9 per cent. of woven fabrics, and these figures are considerably too high for the present state of the trade.—B. B.

*Report on Textile Fibres and derived Products.* Relazione nel. Lab. Chim. Centr. delle Gabelle, 385—402.

THE import duty in Italy on textile fibres and tissues varies according to the proportion of their components; thus on mixed tissues of cotton or wool with silk or tinsel the duty is different according as the proportion of silk is greater or less than 12 or 50 per cent., and on mixed tissues of cotton and wool according as the proportion of wool is greater or less than 50 per cent. Thus in cases of dispute not only a qualitative identification of the tissue is necessary, but also quantitative determinations. The methods adopted for the micro-chemical investigation are based upon the work of von Höhnelt; the direction of the laboratory is now engaged upon an examination of an exact and rapid method for the quantitative separation of various tissues, which is to form the subject of the next publication. Meanwhile the following processes have been adopted: First, for mixtures of cotton and wool, the colouring matter and size are extracted by water containing a trace of sodium carbonate and the tissue then washed with hydrochloric acid, dried and weighed; another portion is digested with 10 per cent. potash solution, which dissolves the wool. Secondly, for mixtures of wool and silk, the size and colouring matter are extracted as before, and the tissue digested in Löwe's solution, which dissolves the silk, but this method is not applicable for Yamamaya, Tussah, and Cyenthia silks, in which cases the method proposed by Höhnelt is used; experiments are being made upon its applicability.

Analyses are given of various mixtures of wool, cotton, and silk sent to the laboratory, and also answers to inquiries as to the nature of various tissues sent for examination. Among the latter the following frauds were detected: a sample denominated velvet plush of silk and cotton was found to consist entirely of Tussah silk, another denominated wool contained 21 per cent. of silk, while a third, supposed to be silk and wool, was only silk. The varnish of various samples consisted principally of resinous matters mixed with oil, but some contained mineral substances such as lead and manganese oxides, barium sulphate and sand; the red colouring matter consisted of ferric oxide and the black of tar. A certain sample of buckram was covered with a layer two millimetres thick, consisting of a mixture of powdered cork, sand, and ferric oxide, the whole cemented together with a resinous substance and a little oil.—V. H. V.

#### PATENT.

*Improvements in Imparting to Fabrics, Threads, and other Articles a Silk-like Lustre.* W. Green, Ramsgate. Eng. Pat. 9879, June 15, 1889. 6d.

It is known that cellulose, suitably treated, forms a substitute for silk. Certain parts of young wood prepared in a state of great purity form the best material for this. It is converted by nitric acid into a pure octo-nitrocellulose which is dissolved in a mixture of 38 parts of ether and 42 parts of alcohol in a proportion of 6.5 per cent. The cellulose thus treated is put in a tinned copper vessel, in which it is kept under a pressure of several atmospheres. The material is forced from the copper vessel through glass tubes with capillary apertures, and in contact with water forms thin threads or filaments which are wound on to bobbins. The nitric acid is at the same time disengaged: "some pyroxylin lose their nitric acid in pure water, but more completely in dilute nitric acid of no greater density than 1.32, and the temperature of which should be caused to decrease slowly from 35° to 25° C. The cellulose thus treated becomes gelatinous and capable of absorbing various substances, particularly colouring matters and salts." The object of the patentee is to extend the use of this article for various purposes. He coats and treats other threads, fabrics, paper, lace, ribbons, buttons, flowers, vases, jewellery, and many other articles with octo-nitrocellulose as above described. In coating threads they are first passed through the octo-nitrocellulose solution, secondly through an aperture by which the superfluous liquid is removed, then through water, and finally wound on to bobbins. A closed vessel must be used to prevent as far as possible the escape of the ether

and alcohol. Another method is to bring the threads into contact with the octo-nitrocellulose, as the latter is forced from a capillary tube, and to cause adherence by giving a twist to the threads. In either case the threads are then to be treated as those of pure cellulose as described above. In treating fabrics, &c. an arrangement is made so that the fabric will pass under or over the tubes through which the cellulose is forced either as threads or as ribbons, the cellulose thus covering the surface of the fabric wholly or in part. By different motions and arrangements of the tubes as well as of the fabrics various patterns may be produced. In some cases adhesive matters or pressure may also be applied to ensure the more perfect union of the cellulose to the fabric. When the material is to be coated on both sides, it is brought into the solution and then passed between rollers. Fabrics thus coated may be used for numerous purposes in lieu of goods made of silk or of silk and other materials. For some purposes a "denitro-cellulose compound, or collodium, or a collodium flexile" may be used instead of octo-nitrocellulose. Moulded, hollow, or other irregular-shaped articles are treated by placing them on trays in a copper vessel. The solution is then run in, until the articles are sufficiently immersed, the superfluous liquid run off, and the coated articles removed and treated as above described. Buttons and many other articles may thus get a silk-like surface. If only a portion of the surface is to be coated with cellulose, this may be effected by pressing the fabric against an engraved roller revolving in the solution. For this purpose, however, the patentee prefers that an ordinary printing arrangement with proper arrangements for coating the engraved roller be fixed in a closed vessel provided with suitable inlets and outlets for the fabric.—H. S.

## VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

*On the Manufacture of Dye-wood Extracts.* C. Feuerlein. Chem. Zeit. 14, 887.

OWING to the great difference in the raw products, it is impracticable to judge of the value of the extract by the percentage of logwood contained in it. Different methods of determining the latter give totally different results, and the quality must depend entirely on the use which the extract is put to. Soxhlet and Brühl have stated that the reason why the dye-wood-extract industry has made so little progress in Germany is that it has been carried on in a less scientific manner. The author, while refuting these remarks, traces the cause to the large duty on extracts in France and America. He advocates an increase in the duty to Germany, which at present amounts to 3 M. per 100 kilos.—A. R.

*Determination of the Value of Dye-wood Extracts.* L. Schreiner. Chem. Zeit. 14, 961—962.

See under XXIII., page 976.

*Test for Fastness to Light and Resistance to Lime of Colouring Matters.* H. Stössel. Chem. Zeit. 14, 903.

MANY colouring matters are now upon the market, consisting of some "base," such as chalk or barium sulphate coloured with an aniline dye (this Journal, 1890, 301), and their fastness cannot always be depended upon. For ascertaining how far they may be expected to resist the action of lime, 1 grm. of the substance is shaken at intervals for six hours with 10 cc. of a normal solution of caustic soda. A check test may be made by shaking another portion of 1 grm. with sugar solution of the same specific gravity (1.046), and comparing the difference in colour. Limewash of the consistency likely to be used is considerably more alkaline than

normal alkali, but any colours likely to fade show tendency to do so when treated as described above.

The fastness to light of such colours may be gauged by exposing them, partly covered with a piece of dark paper, to sunlight for six hours, and comparing the covered and uncovered portions.—B. B.

*Diamond Black.* Farbenfabriken F. Bayer and Co. Chem. Zeit. Rep. 14, 216.

BEFORE dyeing, the wool or other textile fibres are boiled an hour with 10 per cent. glauher salt, and after washing, boiled another half-hour with 2 per cent. potassium bichromate. Both baths may be used for an indefinite time, and the dye-bath may be shaded with other benzidine dyes.

—A. R.

*Anthracene Yellow.* Farbenfabriken F. Bayer and Co. Chem. Zeit. Rep. 14, 216.

THIS dye belongs to the alizarin group, and is correspondingly fast. Instructions for dyeing: mordant with 3 per cent. potassium bichromate and 2 per cent. cream of tartar or 1 per cent. tartaric acid; boil one hour, wash, and dye in a fresh bath with 2 per cent. acetic acid.—A. R.

*The Influence of Olive Oil used in Oiling Wool on the subsequent Dyeing Operations.* A. Horvitz. Färb. Zeit. No. 11, 1890.

ALTHOUGH the oiling of wool necessary before carding is merely a preliminary operation to spinning, it is, nevertheless, of great importance to the dyer, in so far as a proper selection of the oil is essential to the production of an even shade. It is usually supposed that an admixture of resinous oils, mineral oils, and drying oils to the oiling substances creates disturbances in the dyeing process, and this supposition has proved to be correct, although the action of the substances mentioned has not yet been scientifically established. In practice their presence renders the production, especially of light shades, much more difficult, and has not unreasonably been considered as one of the causes of unevenness. The resinous oils and the mineral oils being unsaponifiable are certainly injurious, because they cannot be removed from the woollen fibre by the treatment usual in the manufacture; and in the subsequent dyeing process they are obstructive to an even penetration of the colouring matter into the wool fibre. But this effect being probably produced by all other unsaponifiable fats, the condition made hitherto, that the oils are to contain no resinous or mineral oils, may be extended so far as this: that they are to be free of any unsaponifiable fatty ingredients.

An unsaponifiable fat, which the author frequently found in the oiling substances, is cholesterol. The author repeatedly observed that the presence of cholesterol is more obstructive to an even fixation of the colouring matter than that of any other unsaponifiable ingredient; and he, therefore, recommends that all oils used for wool should be tested for cholesterol.

The detrimental effect of the drying oil may be caused by the wool-fibre becoming enveloped by a coat of varnish, which would partly prevent the entrance of the colouring matter.

The author next discusses the behaviour of olive oil. This substance is obtained as a purer product by pressing the olives in the cold, while the second yield is obtained by boiling the olives and by hot pressing. It is this latter product which is chiefly used for oiling wool.

It consists chiefly of triolein (about 72 per cent.), and contains besides palmitin, arachin, arachinic acid, and very little stearin. According to Schaedler, it invariably also contains cholesterol.

With the usual methods of preparing the oil, the quantity of cholesterol passing into the olive oil will be very small, so that the presence of such traces will scarcely have a perceptible influence. But if the amount of cholesterol in an oil should be as much as 4 per cent., which the author frequently observed, the oil is of the poorest quality, and

has been obtained by unusual methods of preparation. In one instance the author, having extracted cholesterol from dyed pieces that were spotted, examined the olive oil that had been used for oiling the wool. The quantity of cholesterol obtained by saponifying the oil, drying the soap produced, and extracting it with petroleum, was about 3 per cent.

The olive oils of commerce are never pure oils. Adulterations with less expensive oils are very common. An addition of non-drying vegetable oils can only interest the spinner, while in dyeing it can scarcely have any bad effect. An admixture of drying oils, resinous or mineral oils, will, on the contrary, create more or less conspicuous disturbances in dyeing.

The chemist will detect an adulteration with these substances easily by a change in the iodine and saponification equivalents, as well as by deviations in the melting and solidifying points of the fatty acids, while the practical man is limited to qualitative reactions which, as the author remarks, can only be considered as perfectly reliable if, at the same time, confirmed by quantitative tests.

The presence of drying oil may be shown qualitatively as follows:—A well-cleaned copper wire is placed in a mixture of 2 ccm. of nitric acid and 5 ccm. of oil; the mixture is then stirred with a glass rod. If the sample contained a drying oil, the wire, if withdrawn after half an hour, will have a pink shade.

The test for resinous or mineral oil requires the oil to be saponified, the dried soap to be extracted with petroleum ether, and a further examination of the residue after evaporation of the ether. According to Allen, a mixture of 10–12 drops of resinous oil with bromide of tin is coloured a brilliant purple. Bromide of tin may be rapidly prepared by adding bromine, after having shaken it with sulphuric acid for the purpose of removing the water from it, drop by drop on tin filings kept in a well-cooled bottle.

For cholesterol the unsaponifiable portion may be tested by the following reactions, proposed by Schulze:—

1. If a small quantity of cholesterol be carefully evaporated to dryness on the lid of a crucible with a few drops of nitric acid, a yellow spot remains, which, if ammonia be poured on it, assumes a yellowish-red colour.

2. If a sample of cholesterol be rubbed on the lid of a crucible, with a drop of a mixture of three volumes of concentrated sulphuric acid and one volume of solution of ferric chloride, then carefully evaporated to dryness, the undissolved particles assume a violet-red colour which gradually turns more towards blue.

3. If a sample of cholesterol be rubbed together with a little concentrated sulphuric acid, and chloroform be then added, a blood-red solution is produced, which on the admixture of concentrated nitric acid becomes violet, blue, and finally colourless.

If an olive oil destined for oiling wool contains several of these injurious admixtures at the same time, it becomes a matter of great difficulty to answer the question so frequently put in practice as to what extent the oil may have an injurious influence in the further course of the manufacturing operation. Researches in which the quantity of the admixed substances, as well as the amount of damage caused by them, are taken into account, have not yet been made.

The author mentions a point which is not, indeed, of immediate interest to the dyer, but in other respects it is of paramount importance—namely, that all oiling materials for wool should not contain any free acid since it strongly attacks the cards, destroying them in a short time.

## PATENTS.

*Improvements in Machines for Dyeing, Bleaching, and otherwise Treating Yarn in Cop or other Compact Form.* A. Graemiger, Manchester; W. T. Whitehead, Radcliffe; S. Mason and E. A. Leigh, Manchester. Eng. Pat. 9692, June 12, 1889. 8d.

THE improvements relate to the cop-dyeing machine patented by Graemiger (Eng. Pat. 11,497 of 1887), and have for their object the lessening of friction between the

cop-carrier and carrier-body in the same. A double disc cop-carrier, *b b* (Figs. 1 and 2), capable of being intermittently rotated, is now employed. The discs are fitted

against a central stationary carrier body *c*, which is divided into four chambers, *h*<sup>1</sup>, *h*<sup>2</sup>, *h*<sup>3</sup>, *h*<sup>4</sup> (Fig. 1), communicating successively on the rotation of the discs, with the cops *g*

Fig. 1.

Fig. 2.

(shown in Fig. 2) fixed on perforated injection tubes *g* projecting from the outer faces of the discs. Chamber *h*<sup>1</sup> serves for liquor extraction and substitution of the cops, *h*<sup>2</sup> and *h*<sup>3</sup> for saturation and impregnation, and *h*<sup>4</sup> for liquor extraction. Instead of the dead face hitherto left in the carrier body between chambers *h*<sup>1</sup> and *h*<sup>2</sup>, a preliminary extraction chamber, *h*, is formed, connected with an air and liquor separator, *o*, which prevents liquor from entering the air-pump and allows it to be returned to the tank *a* free from air. By means of the cylindrical apparatus *n* the liquor is supplied to the tank in regulated quantity and its level in the same is kept constant.

Fig. 2 is a longitudinal section of a cylindrical machine. The cop-carrier *b* is in this case fitted to rotate against the end of the carrier body *c* instead of around it. The carrier body is formed with segmental chambers for effecting the above-mentioned operations. The cops *g* are placed in rows at equal distances apart round the periphery of the carrier, and each row of the same is connected with a separate segmental cavity, *w*.

In the original specification details are given of the construction and mode of working of the automatic air and liquor separator, liquor charging vessel, and means of closing the vacuum valve, all of which are applicable to the cylindrical as well as to the disc machine.—E. B.

*Improvements in Sizes and Methods for Fixing Colours in Printing and Staining Paper, Cloth, and other Surfaces.* R. Leigh, Bolton. Eng. Pat. 11,938, July 27, 1889. 4d.

Two processes are included in this specification. In the first a size or vehicle for fixing colours is prepared from a

mixture of (a) a solution of rosin in borax, ammonia, or other alkali; (b) a solution of casein in alkali; or a solution of gum, glue, or starch; and (c) a chrome salt. The colour mixed with this vehicle is printed on the fabric and dried in the usual way.

The second process consists in adding powdered gum, rosin, sulphur, or other gummy, resinous, or oily substance not soluble in water, to a mixture of chrome salt and gum, glue, starch, or other binding material, or alternatively to silicate of soda, gluten, or size. The resinous body is either ground up with the colour direct, or first dissolved in turpentine, petroleum spirit or other solvent. In the latter case the resin is precipitated in a finely divided state on mixing with the thickening. In the use of this vehicle the fixation of the colour is effected by the heat of the drying-plates over which the printed fabric passes. By an alternative process the thickening and colour alone are printed and the rosin or gum dusted or padded on to the moist fabric and then dried as before.—W. E. K.

*Improvements in the Production of an Indigo Vat.* A. Ashworth, Manchester. Eng. Pat. 14,246, September 10, 1889. 4d.

A CLEAR vat for the reduction of indigo is prepared by acting on zinc with bisulphite of soda and, when the reduction is complete, precipitating the zinc by addition of sodium sulphide.—W. E. K.

*Improvements in Machinery or Apparatus for Dyeing or Washing Hanks of Yarn.* J. Ashworth, F. Scholes, and R. Hunt, Radcliffe. Eng. Pat. 14,257, September 10, 1889. 6d.

THIS invention relates to that class of machines in which revolving rollers are employed for supporting the yarn in the vat or dyeing cistern. The machine is made double with two sets of "winces" and two dyeing cisterns. A central shaft runs the whole length of the machine between the two cisterns, and is provided with worms at suitable distances apart. These gear into wheels keyed on to shafts set at right angles to the driving shaft. On each end of these counter shafts is fixed a disc carrying three metal prongs or rods for supporting the hanks of yarn.—W. E. K.

*Improvements connected with or applicable to Baths or Vessels containing Liquids used in Electro-plating or Dyeing or the Electrolyte of Storage Batteries and the like.* E. Hopkinson and D. Appleton, Manchester. Eng. Pat. 14,871, September 20, 1889. 6d.

See under XI., page 952.

*Improvements in Hank-dyeing Machines.* R. Gee, Huddersfield. Eng. Pat. 15,455, October 2, 1889. 8d.

FOR the purpose of dyeing hanks of yarn in such a manner that every part is equally exposed to the dye liquor without the felting or intermingling of the threads, an ordinary dye-vessel is provided with two endless chains arranged lengthwise, one at each side of the vat. These are supported and driven by toothed guide pulleys fixed on a moveable framework. To each chain are attached bobbins or "creels" placed in a vertical position, the hanks of yarn being distended horizontally across the machine between the two sets of bobbins. The pulleys are placed at such distances apart that the hanks are fully distended whilst the chains are traversing the upper ones, but when the chains pass down under the lower guide pulleys, they are caused to converge so that the hanks are slackened and open out and thus the threads are fully exposed to the liquor. During the upper traverse of the chain the bobbins carrying the hanks are caused by frictional contact with leather-covered bars to turn a half revolution or thereabouts in order that the portion of yarn around the bobbins may be constantly

changed. The framework carrying the guide pulleys, together with the endless chains and bobbins, are bodily lifted clear of the liquor when the operation is over, this being effected by hydraulic rams.—W. E. K.

*Improvements in Hank-dyeing Machines.* R. Gee, Huddersfield. Eng. Pat. 15,512, October 3, 1889. 8d.

THE hanks of yarn to be dyed are supported vertically between two rectangular frames, one at the bottom the other at the top of the dye vat. The yarn passes around bobbins or "creels" fixed in the two frames, and is distended by springs acting on the bearings of the lower series of bobbins. The axes of the upper creels are geared by a train of toothed wheels which impart a rotary motion to the hanks. The lower frame, by an arrangement of levers worked by an eccentric, is alternately raised and lowered, the effect being that the hanks of yarn are slackened intermittently and the threads opened out, this action allowing the dye to penetrate to the individual fibres.

—W. E. K.

*Improvements in or relating to Bleaching and Methods for Producing Bleaching Agents.* L. Schreiner, Stuttgart, Germany. Eng. Pat. 15,671, October 5, 1889. 6d.

A BLEACHING material, termed "ozonin," is prepared by dissolving turpentine in a potash-resin soap, and oxidising the product by atmospheric air or by peroxide of hydrogen. "Ozonin" also acts as a powerful antiseptic.—W. E. K.

*Improvements in Producing Azo-Colours on or in Cotton or other Textile Fibre or Fabrics.* T. Holliday, Huddersfield. Eng. Pat. 16,156, October 14, 1889. 6d.

THIS invention relates to a process of dyeing textile fibres by the combination of  $\alpha$ - or  $\beta$ -naphthol with the diazotised various thio-compounds derived from aniline, toluidines, xyldines, emidines, or naphthylamines, such combinations taking place in the presence of the fibre. For example: hydrochloride of thioparatoluidine is converted into the diazo-compound by treatment with hydrochloric acid and nitrite of soda, the cotton dipped into or padded with this solution, and then (with or without drying) passed into a solution of one of the naphthols dissolved in caustic soda; or the order of these operations may be reversed. To produce coloured patterns, as in calico-printing, the cloth is impregnated with the naphthol solution and dried, and the diazo solution, suitably thickened, is then printed on.

—W. E. K.

*A New or Improved Method of Bleaching Wood, Bobbins, Reels, and other Articles made from Wood.* A. Greg, Bolton. Eng. Pat. 16,368, October 17, 1889. 4d.

THE articles are treated successively with baths of lime or other alkali, chloride of lime, and sodium hyposulphite. They are then stopped with burning sulphur, or treated with a solution of sulphurous acid, and finally treated with water containing acetic acid "for the purpose of replacing the natural acid displaced by the before-mentioned baths."

—W. E. K.

*A New or Improved Method of Dyeing Aniline Black.* L. Schreiner, Stuttgart, Germany. Eng. Pat. 19,490, December 4, 1889. 4d.

ALBUMEN, casein or analogous glutinous bodies are mixed with the solution of aniline salt used in dyeing aniline black, and these are coagulated by the reagents subsequently employed for the oxidation of the aniline.—W. E. K.

*Improvements in the Development or Treatment of Colouring Matters in Textile Fabrics or Materials.* J. J. Hart, Lowell, Mass., U.S.A. Eng. Pat. 8541, June 3, 1890. 8d.

This invention relates to those processes in calico-printing in which a colouring matter and mordant or other reacting body, after having been printed and steamed, require a supplementary treatment with a chemical reagent for the development or complete fixation of colour; as for example, the treatment with bichromate of potash in the case of catechu colours, or with tartar-emetic in the case of aniline colours fixed by means of tannic acid. It is the usual practice to pass the fabric through a hot bath of these supplementary reagents, but this process is objectionable on account of detached colour-lake, and foreign bodies contaminating the bath and staining the fabric. To avoid such damage, by this invention the fabric is passed through a cold solution of the reagent, the excess of solution squeezed out by pressure rollers, and the necessary chemical reaction is then effected by passing the fabric over cylinders heated by steam or through a steam-chest.—W. E. K.

*An Improved Blue for Laundry and other Colouring Purposes.* G. R. B. Kempton, West Ham. Eng. Pat. 10,616, July 9, 1890. 4d.

To a suitable proportion of a soluble salt, sufficient "Aniline blue, Prussian blue, Chinese blue, Indigo blue, or Ultramarine blue" in solution is added, and the whole evaporated to dryness, after which the resulting crystalline mass is ready for use.—K. M.

*Improvements in Centrifugal Leather-Dyeing Machines.* J. Kristen, Brum, Moravia. Eng. Pat. 11,255, July 18, 1890. 6d.

OVER a circular horizontal revolving table, the upper surface of which is formed of a glass plate (in order to facilitate the adhesion of the hide) a radial perforated pipe is fixed, and this is connected with a tank that supplies the dyeing liquor. The surplus liquor projected beyond the edge of the plate is received in a conical flanged tank which surrounds the table, and is returned to the liquor tank by means of a pump.—W. E. K.

*Improvements in Yarn-Dyeing Machines.* H. H. Lake, London. From The Leonard Weldon Dyeing Machine Company, Amsterdam, U.S.A. Eng. Pat. 11,873, July 29, 1890. 6d.

THIS invention relates to that class of dyeing machines in which the skeins of yarn are carried on bars affixed to the interior of a frame or reel which rotates within the dye vat. The improvement consists in disposing the respective sets of yarn-carrying bars in planes oblique to the radius of the rotating wheel, so that the yarn is drawn partly endwise and partly side-ways through the liquor, and in consequence the yarn is dyed more evenly and the strain upon it reduced.—W. E. K.

—W. E. K.

## VII.—ACIDS, ALKALIS, AND SALTS.

*The Relative Basic Properties of Aluminium and Ferric Hydroxides.* A. Schneider. *Annalen*, 257, 359—380.

Already abstracted from *Ber.* 23, 1349—1354 (this Journal, 1890, 837).

*Potassium Tetra- and Penta-thionate.* A. Foek and K. Klüss. *Ber.* 23, 2428—2432.

RAMMELSBERG (*Kryst. Phys. Chem.* I., 495) described a potassium pentathionate, which it was suggested in Graham-Otto's book (5 Edition III., 125) was thiosulphate or tetrathionate. Debins (*Ann.* 244, 76) placed the existence of

pentathionic acid beyond doubt by preparing and analysing with Lewes the pure potassium salt. The authors suggest that Lewes (*J. Chem. Soc.* 39, 68; 41, 300) and Shaw (*J. Chem. Soc.* 43, 351) worked with an impure preparation.

The crystals of tetrathionate prepared by the authors belong to the monosymmetric system, and measurements are given in detail. Both in Rammelsberg's original preparation and in the authors' a peculiar hemimorphic or hemihedral formation was observed in some of the crystals, which will be more fully described in the *Zeits. für Krystallographie*.

The authors prepared the pentathionate as follows:—Sulphuretted hydrogen was led for two hours every day for 10 days in a slow stream through a litre of a nearly saturated solution of sulphur dioxide. At the end of this time the smell of sulphur dioxide had gone. The Wackenroder's solution prepared in this way was concentrated in a water-bath at a temperature of 35°, and then filtered from precipitated sulphur; 85 cc. of sp. gr. 1.241 were obtained, which according to Kessler's tables would contain 33 per cent. of  $S_5O_3$ . The calculated quantity of potassium acetate was then added, the liquid put into a large watch-glass, and the water and acetic acid evaporated by a current of air. The residual mass after drying by pressure weighed about 25 grms., and was dissolved in 30 cc. of a 1 per cent. solution of sulphuric acid at a temperature of 45°, the solution filtered from sulphur and crystallised over sulphuric acid. The first two crops consisted nearly entirely of tetrathionate. The following crops contained pentathionate. By fractional crystallisation about 10 grms. of pure tetrathionate and 6 grms. of pure pentathionate were obtained. The crystals of the latter belong to the rhombic system and measurements of them are given in the original paper.

—H. S. P.

*On the Red Colouring of Sulphuric Acid.* R. Nörrenberg. *Chem. Ind.* 13, 363—364.

SOME consumers of vitriol object to a product possessing a red colour. This tinge is often produced in perfectly colourless vitriol when kept in iron vessels, and is due to the action of ferrous sulphate in solution on nitrous compounds; these are reduced into nitrous oxide, which dissolves in sulphuric acid with a red colour. The same observation can be made in the leading chambers of a set, the rose colour or the dark red appearance of the vitriol being here traceable to the iron, which is carried forward with the sulphurous acid from the burners. Addition of ammonium sulphate destroys the nitrous compounds and thus effectually prevents any red colour.—H. A.

## PATENTS.

*Improvements in Apparatus for Generating Carbonic Acid Gas.* F. Foster, Hoxton. Eng. Pat. 17,569, December 1, 1888. Reprint. 6d.

THE apparatus has been already described in this Journal, 1889, 983.—H. A.

*Improvements in and Connected with the Utilisation of Sulphate of Iron Galvanising Pickle.* T. Parker and A. E. Robinson, Wolverhampton. Eng. Pat. 19,554, June 29, 1889. 4d.

See under X., page 949.

*Improvements in or Appertaining to the Manufacture of Peroxide of Lead, or Alkaline Plumbate and By-Products.* P. Naef, Northwich. Eng. Pat. 11,962, July 27, 1889. 6d.

THE principal object is to effect the oxidation of oxide of lead to peroxide more economically than hitherto. Nitrate of sodium or other nitrates are employed for this oxidation, nitrites being obtained as a valuable by-product. The

oxidation may be effected also by atmospheric oxygen directly. In either case, as intermediate product, a compound of peroxide of lead with an alkali or alkaline earth is obtained, from which subsequently peroxide of lead is separated. Metallic lead may also be used for making the peroxide. The lead or lead oxide is oxidised in presence of caustic soda, by means of nitre or a blast of air, at an elevated temperature, and the sodium plumbate so obtained is first washed and then decomposed with boiling water into lead peroxide and caustic soda. The sodium nitrate is thereby converted into sodium nitrite, which is found in the wash-waters of the sodium plumbate melt, along with caustic soda. These wash-waters are boiled down to concentrate them, and returned to the process after addition of caustic soda. When rich enough in nitrite, this is separated either by boiling down to a suitable strength and allowing the nitrite to crystallise, or else by carbonating and evaporating the liquor and separating the sodium carbonate by fishing out the monohydrated salt during evaporation or crystallising out by cooling, the sodium nitrite remaining in solution.

For the manufacture of voluminous and finely divided peroxide, the dense peroxide obtained from any source is heated with highly concentrated caustic soda till the mass has become very consistent. The product is washed and decomposed in the usual way.—H. A.

*Improvements in and connected with Apparatus for Producing Gaseous Hydrochloric Acid.* W. L. Wise, London. From Solvay and Co., Brussels, Belgium. Eng. Pat. 15,531, October 3, 1889. 8d.

The apparatus consists of two main parts: a horizontal rectangular distilling vessel provided with a partial partition, and containing sulphuric acid of about 140° Tw. or a strong solution of calcium chloride, and in connexion with this, and on the same level, an evaporating vessel with partition, for evaporating the dehydrating agent to its original degree of concentration.

A fine stream of hydrochloric acid is introduced in one end of the distilling vessel, where it mixes with the hot vitriol or calcium chloride propelled forward from the concentrating vessel, by means of a puddle-wheel or helix, or an air injector. While the mixture circulates along the partition, gaseous hydrochloric acid is given off, which may be condensed. The dilute sulphuric acid leaves at the other end of the distiller, and entering the evaporating vessel, takes the course formed by the partition wall, and returns to the distiller with the desired degree of concentration.—H. A.

*Improvements in the Manufacture of Nitrite of Soda.* J. Grossmann, Manchester. Eng. Pat. 15,655, October 5, 1889. 4d.

Sodium nitrate and calcium sulphide (or alkali waste which has previously been freed from cinders and coal) are heated together in quantities represented by the following equation:—

In lixiviating the resulting mass, boiling down and cooling, the impurities are separated from the mother-liquor, which will contain the sodium nitrite.—H. A.

*Improvements in the Method of Producing Chloride of Lead.* W. Shapleigh, Camden, U.S.A. Eng. Pat. 16,212, October 15, 1889. 8d.

The improvement consists in a better utilisation of the lead, nitric acid, and hydrochloric acid, as compared with the old process.

Finely-divided lead is introduced into dilute nitric acid, while a blast of air is forced through the vessel, to agitate and cool its contents and to oxidise the nitrous compounds, which will dissolve in the liquor. Part of the strong solution of lead nitrate is drawn off, decomposed with hydrochloric acid, the lead chloride collected on a filter, and the remaining part of the lead nitrate solution added to the

mother-liquor consisting of nitric acid and excess of hydrochloric acid. An additional quantity of lead chloride is obtained, and the nitric acid, being completely freed from hydrochloric acid, is fit to return to the process.—H. A.

*Process for obtaining Salts of Thorium, Zirconium, and like Metals from their Ores or from Waste Residues of Hoods used for Incandescent Gas Lighting.* O. Imray, London. From W. MacKean, Paris, France. Eng. Pat. 16,555, October 19, 1889. 6d.

THORIUM salts are obtained from the finely-ground ore by repeatedly digesting with hydrochloric acid, and treatment with an alkaline sulphide. Zirconium salts are obtained by fusing the ore with caustic alkali, baryta, or strontia, digesting the powdered melt with acid and water and treating the acid solution with an alkaline sulphide, precipitating the oxide with an alkali, and redissolving in hydrochloric acid.

The chlorides of zirconium and thorium are purified by repeatedly precipitating with sodium hyposulphite, and redissolving in hydrochloric acid, and finally, by precipitating with ammonia and dissolving in hydrochloric acid.

The separation of zirconium, thorium, lanthanum, and cerium, which may be contained in the waste residues of hoods, is based on the insolubility of the hyposulphites of zirconium and thorium in weak acid solutions, and on the solubility of thorium oxalate. Both lanthanum and cerium oxalate are insoluble, but their oxides can be separated by means of dilute nitric acid, which dissolves that of lanthanum.

—H. A.

*Improvements in obtaining Caustic Soda or Caustic Potash by means of Boracic Acid.* W. Garraway, Glasgow. Eng. Pat. 17,395, November 2, 1889. 4d.

A MIXTURE of boracic acid (3 to 4 mols. proportions) and common salt (2 mols.), when fused together, gives off hydrochloric acid, with formation of sodium metaborate or sodium pyroborate. The furnace mass is ground, dissolved in water, and decomposed with lime. Caustic soda remains in solution, whilst calcium metaborate or calcium pyroborate is precipitated. The boracic acid is regenerated therefrom by decomposition with the hydrochloric acid previously formed, or by any other suitable acid.

An admixture of nitre or salt cake, also injection of steam, facilitates the decomposition in the furnace.—H. A.

## VIII.—GLASS, POTTERY, AND EARTHENWARE.

*Recent Advances in the Pottery Trade.* Dingl. Polyt. J. 276, 580—596.

CERTAIN ornamental tiles of French make with a thick rose-coloured enamel, often showing a good many cracks, are glazed, according to a note in *Sprechsaal*, 1889, 597, as follows:—100 parts by weight of pure quartz sand are fused with 200 of red lead free from iron, and 5 of borate of lime, the melt quenched, ground up, and mixed with 10—30 per cent. of ruby glass having gold as its colouring material.

The yellow-green or bright red-brown earthenware vessels of Seinde are glazed with a lead silicate coloured with ochre or copper ashes (*Sprechsaal*, 1889, 183).

*Porcelain and Earthenware Glazes.*—The substitution of a leadless glaze for those in common use containing that metal is in many ways desirable, but the facility of production and the low cost due to the fusibility of lead glazes and the consequent small consumption of fuel in their production, lead to their retention.

G. Bücher, in the Jahresb. k.k. Fachschule f. Thonind. in Znaim defines the conditions which govern the successful production of a leadless glaze. A good refractory clay "fat" enough to take up one-third its weight of quartz sand, or a clay containing sand, but free from much lime, should be used. The simplest and cheapest glaze of the kind is made by dissolving 8 parts by weight of pearl-ash in hot water and stirring in 100 parts of dry ferruginous well-washed loam, mixed with 20 of yellow ochre. The goods are fired at an incipient white heat, and allowed to cool with the furnace closed and all cracks luted up; while thus cooling the copper-brown colour proper to the glaze is developed. A better class of pottery is made by using the same clay for the body of the ware, and the same glaze for the outside, but lining the inside with a mixture of 40 parts of white clay, 15 of fine sand, 15 of ground porcelain, and 20 of felspar, which is afterwards glazed with a composition consisting of 11 parts of felspar, 15 of calcined sand, 9 of ground porcelain, 9 of chalk, and  $3\frac{1}{2}$  of calcined kaolin. The furnace is hermetically closed while cooling as before. Instead of making the body of the ware of clay, a composition approaching that of porcelain is attained by using 48 parts of white clay, 6 of ground porcelain, 20 of calcined white sand, and 6 of felspar; in this case the outside is glazed with the brown mixture before firing, then the white glaze given above applied to the inside, and the firing repeated.

Seger, in continuation of his earlier work (Thonind. 1884, 46) has recently published some more valuable matter (Thonind. 1889, 524, 538, 553, 566) (for an abstract of a précis of this work see this Journal, 1890, 68). A more detailed account giving some of his recipes is as follows:—In pursuance of the attempt to prepare fusible glazes free from lead, various mixtures containing boric acid as a characteristic ingredient were tried in place of those containing baryta mentioned in his earlier paper. Attention was paid only to those glazes, the fusing points of which were below that of gold. The plan of investigation adopted was to prepare a mixture with the highest permissible amount of alkali and smallest quantity of lime and pass gradually to the other extreme. For each of these, mixtures were made in which the proportion of the other ingredients (silica, alumina, and boric acid) varied, and their behaviour examined.

#### I.—Glazes in which the bases have the relation—

A glaze of the composition  $0.6 K_2O(Na_2O)$ ,  $0.4 CaO$ ,  $0.1 Al_2O_3$ ,  $2.5 SiO_2$ ,  $0.5 B_2O_3$ , fused at a temperature between the melting point of silver and that of the alloy 80 parts of silver to 20 of gold, and gave a smooth surface, moreover, attacking the colours beneath it less than most lead glazes; it was, however, necessary to use a highly siliceous well-burnt material for the body of the ware, e.g., 35 parts of clay, 5 of felspar, and 60 of quartz, burnt at a temperature corresponding to the cone known as Nos. 9 or 10; otherwise crackling was apt to occur. Such a glaze results from the prescription:—

	Parts by Weight.
Carbonate of soda .....	31.80
Marble .....	20.00
Ground quartz .....	75.00
Boric acid .....	31.00
Kaolin .....	12.95

On raising the proportion of alumina, silica, and boric acid until the formula  $0.6 K_2O(Na_2O)$ ,  $0.4 CaO$ ,  $0.6 Al_2O_3$ ,  $5.0 SiO_2$ ,  $1.0 B_2O_3$  was reached, a glaze was prepared which was white and opaque on slow cooling; a convenient mixture would be:—

Nitre .....	30.80
Borax .....	47.75
Carbonate of soda .....	2.65
Marble .....	20.00
Kaolin .....	77.70
Quartz .....	114.00

#### II.—Glazes in which the bases have the relation—

A glaze from materials similar to those just mentioned and having the composition expressed by the formula  $0.5 K_2O$ ,  $0.5 CaO$ ,  $0.1 Al_2O_3$ ,  $2.7 SiO_2$ ,  $0.5 B_2O_3$  gave a smooth clear film at a temperature about that of the melting points of the alloys 20 gold to 80 silver, and 50 gold to 50 silver; very siliceous material was however necessary for the body of the ware. One of the composition  $0.3 K_2O$ ,  $0.2 Na_2O$ ,  $0.5 CaO$ ,  $0.6 Al_2O_3$ ,  $5 SiO_2$ ,  $1 B_2O_3$ , proved better adapted for a clay richer in alumina.

#### III.—Glazes in which the bases have the relation—

A glaze of the composition  $0.2 K_2O$ ,  $0.2 Na_2O$ ,  $0.6 CaO$ ,  $0.6 Al_2O_3$ ,  $5 SiO_2$ ,  $1 B_2O_3$ , and similar glazes richer in alumina, gave good results, and are of commercial value; they melt somewhat below the fusing point of gold. Those poorer in silica and alumina are of little use from their tendency to become turbid.

#### IV.—Glazes in which the bases have the relation—

No glaze of practical importance was produced, but a series of three with gradually increasing proportions of boric acid showed the influence of that substance very clearly, that containing  $0.5 B_2O_3$  giving a clear glass, while that with  $1.0 B_2O_3$  was opalescent, and that with  $2.0 B_2O_3$  distinctly milky.

#### V. and VI.—Glazes in which the bases have the relation—

A persistent and increasing tendency to become opalescent or milky characterised these and made them of little value.

The deductions from these experiments are that the conditions governing the successful application of such leadless glazes are more rigid than those for lead glazes; nevertheless the former could replace the latter for many purposes. In general those glazes containing much alkali are best for pottery made of highly siliceous clay, while those with more lime suit a material richer in alumina.

**Copper Red Glazes.**—Lauth and Dutailly have experimented in this direction; an abstract of their results may be found in this Journal, 1890, 68.

**Pink Mixture.**—Some recipes for a pink glaze on stoneware and majolica appear in Sprechsal, 1889, 706. One part of potassium bichromate is rubbed down with water and alcohol, with the gradual addition of 8 parts of powdered marble and "16 cbm. 5" of pure zinc oxide, and the almost dry mixture thoroughly ground together, then fired at the temperature usual for stoneware, washed with dilute hydrochloric acid until the washings are colourless, heated again and rewashed. The following mixture after ignition can be used as a diluent to give a suitable shade of colour: 2 parts stannic oxide, two of silica, one of powdered marble. Three different tints can then be prepared thus:—

Dark red...	{ 5 parts dried "pink mixture."
	{ 7 parts ignited "diluent."
Purple.....	{ 8 parts "dark red."
	{ 1 part "CaO <sub>3</sub> " (2 CaCO <sub>3</sub> ) (finely ground)
Cardinal...	{ 12 parts "dark red."
	{ 1 part calcium carbonate.

These colouring matters are mixed with 8 parts of one or other of the following mixtures:—

—	For Majolica Ware.	For Stone Ware.
Ground quartz.....	22.5	35
Borax (crystallised).....	18.5	10
Red lead.....	30.5	25
Kaolin (dried and sifted)	5.0	12
Chalk (levigated).....	7.0	18
Powdered felspar .....	16.5	..

A colour for porcelain or stoneware called *coralline red* may be prepared according to the *Deutsche Töpfer-oder Ziegler-Zeitung* 26, 796, thus: 20·40 parts of lead chromate are mixed with 67·33 of red lead and 12·27 of quartz, and the mixture fused to a clear melt, which is then powdered and mixed in about the proportion of 3:1 with either of the two following compositions:—

	I.	II.
Red lead.....	80	80
Quartz .....	100	20
Boric acid .....	20	..

No. I. is used for high and II. for low temperatures.

*Protection from Lead Poisoning in Potteries.*—N. A. Ruskitt recommends the adoption of the following regulations:—(1.) The conversion of metallic lead into lead oxide must only be effected after admixture of quartz sand or lead glass. Red lead must be mixed with quartz before melting. (2.) The furnaces in which such fusion is effected must be shut off from the workrooms so that no fumes can reach them. (3.) The flue must be so constructed that no injurious vapours escape. (4.) Grinding and stirring the glazing mixtures should not be done by hand. (5.) Children under 15 years of age should not be employed. (6.) The consumption of food and drink should be prohibited in the workrooms. (7.) The same regulations should apply to sleeping. (8.) The workshops must be provided with a good water supply and adequate sanitary arrangements. (9.) All workrooms must be roomy, bright, clean, well ventilated, and kept at a temperature of 16° C. (10.) Drunken or sickly persons should not be employed. (11.) All work in connexion with lead before its conversion into silicate should be carried on in a separate part of the works.—B. B.

*Direct Employment of Ceramic Colours with or without Glaze.* Deville, Pailette, and Co. *Monit. Céram. Verr.* 1890, 110.

SILICIC acid, which has been precipitated from a soluble silicate with hydrochloric acid is applied with a brush. The silicic acid combines with the metal and the colour. By an admixture of tribasic borate of lead the colour may be made lustrous while a dull appearance is best given by using silica powder. When the painting is to be glazed the article is burnt in a muffle-stove at a bright red heat, and then sprinkled with the following enamel mixture: 20 grms. of silica, 60 grms. of red lead, 50 grms. of borax, 10 grms. of saltpetre, 3 grms. of soda, and 1—1·2 grms. of zinc oxide. —A. R.

*New Porcelain and Glass Colours and their Fixation without Fire.* F. Babterrosses. *Deutsche Töpfer-Zeit.* 1890, 14, 187.

ORDINARY water colours are used, which are rubbed down with a particular mixture consisting of two solutions A and B. Solution A consists of 100 parts of a syrup of potassium water glass, to which has been added 10 parts of a lead acetate solution (15 parts lead acetate in 100 parts water) and stirred by an air stream until well mixed. Solution B consists of 50 parts of borax dissolved in 100 parts warm water and 20 parts of glycerol. Sixty parts of solution A and 40 parts of solution B are used in rubbing down the colours and for thinning, water and solution B in equal parts. After the articles have been painted they are placed in a bath made as follows: 1 part of borax is dissolved in 12 parts water and mixed in a gutta-percha flask with 50 parts hydrochloric acid, 10 parts sulphuric acid and 3 parts hydrofluoric acid. After the articles have been immersed 10 minutes in the bath they are taken out and washed with clean water. The colour appears as if burnt in.

—A. L. S.

*Decoration of Glass and Porcelain by Aluminium.* Gehring. *Monit. Céram. et Verr.* 1890, 21, 88.

ALUMINIUM is rubbed down with gum or oil and applied to the article to be decorated with a brush. The firing is done in a muffle and the heat slowly increased up to a red heat; the aluminium becomes first yellow, then brown, and finally white. Gold or enamel may be applied to the aluminium, or it may be allowed to remain matt or polished with a steel brush or an agate.—A. L. S.

#### PATENT.

*Improvements in Gas-fired Kilns for Burning or Heating Pottery and for other Purposes.* J. Holroyd, Leeds, and H. Wilson, Stafford. Eng. Pat. 3583, March 8, 1888. (Second Edition.) 8d.

See this Journal, 1889, 285.

## IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

*Recent Improvements in Building and Paving Materials.* *Dingl. Polyt. J.* 276, 578—580.

E. RYAN has described in *The Michigan Engineers Annual*, a new kind of paving in use at Nashville, Tenn., which consists of ordinary stones soaked in coal-tar pitch set edgewise on a solid foundation of macadam and sand, and well rammed down; after four years' hard wear but little deterioration has taken place. The cost of preparing and laying the stones thus treated on a ready prepared surface is 1·8 dollars per square yard. A patented modification of this plan consists in covering the levelled surface of the pavement with 3—4 inches of sand, levelling this and covering it with tarred boarding, then spreading another even layer of sand about 1·5 in. in thickness, and placing on this the prepared bricks mentioned above, set edgewise and zigzag, and filling up all joints and crevices with another layer of sand. Besides this method two others are in use: in the first two layers of tiles are used, one set flat, the other on edge, and the whole filled in with sand; the other is the ordinary paving with broken stone or concrete; of these neither is as good as that previously described, and their cost is greater. In any case it is essential that good clay be used for making the tiles, it being necessary for it to be reducible to an impalpable powder when dry; a coarse clay of the right composition may be utilised by calcining and grinding. G. J. Snelus has analysed the ganister bricks of the firm *Grayson, Lowood, & Co.*, and finds them to have the composition  $\text{SiO}_2 = 95\cdot40$ ,  $\text{Al}_2\text{O}_3 = 3\cdot10$ ,  $\text{CaO} = 1\cdot68$  parts per cent. respectively. The lime is added as a binding material; the bricks do not expand at high temperatures.

—B. B.

*Magnesia in Portland Cement.* R. Dyckerhoff. *Chem. Zeit.* 14, 906.

THE author has already pointed out (this Journal, 1889, 781) the dangerous character of cements rich in magnesia, their tendency being to expand slowly after setting to the serious detriment of concrete or mortar in which they may be used. Particularly objectionable are they, inasmuch as the ordinary tests such as the "Darrprobe" (firing test) (this Journal, 1889, 781) fail to detect them, careful measurement of their expansion giving also only doubtful indications unless at least half a year has elapsed since gauging. He is disposed to fix the maximum permissible amount of magnesia in Portland cement at 4 per cent., and the Association of German Cement Manufacturers has formed a committee to report on the subject; such makers as are using dolomitic material being specially interested.—B. B.

## PATENTS.

*Improvements in the Method of and Apparatus for Building up the Inside of Kilns for Burning Enamelled Bricks and Tiles.* A. Taylor, Hipperholme. Eng. Pat. 13,036, August 19, 1889. 6d.

In burning enamelled bricks or tiles it has hitherto been the custom to support them in the kiln on large fireclay slabs resting on firebricks at each end; such slabs crack after once or twice using, and the object of the patentee is to avoid this inconvenience. The cracking being largely due to the weight of the bricks, the plan is adopted of substituting a number of slabs of the following shape  F, which are recessed so as to fit into each other and form a series of rectangular chambers in each of which a single brick is burnt.—B. B.

*Improvements in the Manufacture of Glazed Bricks and Tiles.* A. J. Clay, Stoke-on-Trent. Eng. Pat. 14,653, September 17, 1889. 6d.

ATTEMPTS have been made to manufacture glazed bricks from London clay, which have been unsuccessful owing to the non-refractory character of that material causing it to sinter or fuse below the melting point of the glaze. The patentee's process consists in adding 15–30 per cent. of silica in the form of sand or burnt and pulverised flints to the clay, the right proportion being ascertained by exposing trial mixtures in a kiln by the side of the glaze proposed to be used, the proper mixture agglomerating at a temperature above that at which the glaze melts. The mixture is pugged in the usual way, the bricks moulded, dried, and given a preliminary coating of a mixture consisting of 3 parts by weight of white lead, 2 of ground Cornish stone, and 1 of "Devonshire prepared potters best ball clay," and 10 parts of water. A suitable glazing mixture is then applied and the bricks fired.—B. B.

*Improvements in the Method of Burning Lime, and in Kilns therefor.* A. Bishop, Brockham. Eng. Pat. 14,997, September 23, 1889. 8d.

The patentee endeavours to combine to some extent the good qualities of the old fashioned "flare kiln," which produces lime of good colour, and those of modern continuous processes which are economical of fuel. The kiln is preferably built in the ordinary way so that the upper part just emerges from the ground. From the top of the kiln proper rises a cylindrical shaft, into which the charge of limestone together with a little fuel is tipped, and round the base of the main shaft and leading into the body of the kiln (which is roughly a reversed truncated cone) are smaller shafts (about eight in number), provided with covers, through which small charges of house coal siftings are from time to time introduced. The burning takes place in the ordinary way, save that each charge before reaching the zone of combustion is dried by the burnt gases, and that the flame given by the bituminous fuel put in at the side is drawn into the centre of the kiln and burns the lime much as in a flare kiln.

Air inlets formed in the walls of the base of the kiln are brought into use when a specially vigorous combustion is desired.—B. B.

*Improvements in the Manufacture of Plaster of Paris and in the Utilisation of Waste or Cheap Material therefor.* W. J. Oswald, Stoke-on-Trent; S. R. Ashwell and J. A. Cooke, Nottingham. Eng. Pat. 15,406, October 1, 1889. 4d.

Old plaster of Paris moulds, casts, or other waste, or artificial gypsum, are broken up in small pieces or formed into nuts and "burned" in kilns at a temperature between 95°–300° C. The kilns are provided with mechanical stirrers. The product so obtained possesses the property of setting with water.—H. A.

*An Improved Marine Cement.* F. C. Goodall, Richmond. Eng. Pat. 6711, May 1, 1890. 4d.

Forty parts of (melted) hard asphaltum, 40 parts of liquid asphaltum, 8 parts of boiled oil and 12 parts of finely ground corkwood intimately mixed constitute the cement.—K. M.

*Improvements in Bricks for Building Purposes.* D. Hart, Aberdare. Eng. Pat. 9239, June 11, 1890. 6d.

The patentee claims the manufacture of bricks with corresponding projections and depressions, interlocking in use and adding to the stability of the building of which they form part.—B. B.

## X.—METALLURGY.

*On Certain Ternary Alloys.* Parts I. and II. C. R. Alder-Wright and C. Thompson. Proc. Roy. Soc. 45, 461, and 48, 25–45.

THE authors, having had occasion to examine technically various mixtures of lead, zinc, and tin, noticed that whilst in certain cases these three metals could be fused together and intermixed so as to form a homogeneous alloy exhibiting no alteration on standing molten for some hours, this was by no means universally the case, especially with mixtures where the proportion of tin was materially below some 38 per cent. of the total mass; in such cases the fused mass separated into two dissimilar alloys, the heavier one mainly consisting of lead with some tin and zinc, and the lighter one chiefly containing zinc with some tin and lead. On preparing several series of mixtures where the proportion of tin gradually increased from 0 upwards, it was found that a variation of temperature of from below 600° C. to about 700° produced but little effect on the way in which a given mass divided itself into two alloys; but that at higher temperatures approximating to 800°, a measurable difference was discernible. On plotting curves with the percentages of tin in the heavier alloys as abscissæ, and those of zinc as ordinates, it was found that the solubility of zinc in lead-tin increased regularly as the proportion of tin present increased, the solubility curve at 800° distinctly overlying that at 650°. Similarly the solubility curves of lead in zinc-tin obtained in the same way with the lighter alloys exhibited analogous characters, the amount of lead dissolved by zinc increasing regularly as the quantity of tin present increased, and the solubility being uniformly greater at 800° than at 650°. A curious behaviour was noticed as regards the way in which the tin distributed itself between the two alloys; with small proportions of tin the lighter alloy contained most, the difference rising to a maximum when the entire mass contained 14 to 16 per cent. of tin; after which the difference diminished again until the entire mass contained 25 to 28 per cent., when both alloys contained the same percentage of tin. With still greater proportions the lighter alloy contained less tin than the heavier one; so that on plotting curves with the tin percentages in one alloy as abscissæ and the differences (+ or –) as ordinates, the curves rose from the origin to a maximum elevation, then fell again, and finally crossed the base line, and sank below it. It was found that the values of the ordinates were slightly variable with the composition of the total mass employed, although in all cases the character of the curve was the same; when the ratio of lead to zinc in the entire mass was 2:1, the curve underlay that obtained with mixtures where the ratio was 1:1; which again underlay that obtained with mixtures where the ratio was 1:2. On the other hand, whatever the ratio between lead and zinc might be, in every case the two alloys found corresponded with two points (*conjugate points*) lying respectively on the solubility curves of lead in zinc-tin, and of zinc in lead-tin, pertaining to the particular temperature employed.

Results in some respects similar, in others quite different, were obtained with other ternary alloys, the examination of some of which is still in progress. When lead and zinc are fused along with silver, or with cadmium, or with antimony, the masses separate into two different alloys when the three metals used are outside of certain limiting ratios with respect to one another; and the same remark applies to mixtures of bismuth and zinc, of lead and aluminium, and of bismuth and aluminium, with either tin or silver as third metal; but with some of these mixtures the solubility curves differ considerably from those observed with lead, zinc, and tin. Thus, in presence of tin, a given quantity of lead will take up considerably more zinc than it will if an equal weight of silver be substituted for the tin; and, similarly, a given weight of zinc will dissolve more lead in presence of a certain quantity of tin than it will if an equal amount of silver be substituted for the tin. Again, according to experiments still in progress, the way in which the tin divides itself between the heavier and lighter alloys is quite different with mixtures of bismuth, zinc, and tin from that above described with mixtures of lead, zinc, and tin; instead of the curve representing the results rising above the base line to a maximum and then descending again, it regularly sinks away from the base line: i.e., the heavier alloy always contains the most tin, the more so the greater the amount of tin in the total mass.

With mixtures of lead, zinc, and silver some remarkable numerical results were obtained, leading to the conclusion that two definite compounds,  $\text{AgZn}_5$  and  $\text{Ag}_2\text{Zn}_5$ , exist, the formation of which modifies the character of the solubility curves deduced. The first of these dissolves lead, and is itself dissolved by lead, to a greater extent than either pure zinc or the alloy  $\text{AgZn}_5$ ; so that when the lighter alloy formed contains silver and zinc in just the right proportions to form  $\text{AgZn}_5$ , more lead is dissolved therein than is the case with alloys either richer or poorer in silver. Moreover, this alloy is of an unstable character, so that if a saturated solution of lead therein be kept molten for a long time under favourable conditions, the mixture (at first perfectly homogeneous) gradually divides itself into two alloys, owing apparently to the breaking up of  $\text{AgZn}_5$  into free zinc and  $\text{Ag}_2\text{Zn}_5$ , the result of which is that more or less lead is thrown out of solution, sinking to the bottom and carrying with it a little zinc and silver. In the same way lead containing  $\text{AgZn}_5$  in solution, when kept molten for a long time, becomes changed; the solution, at first homogeneous, by-and-by forms two different alloys, because the breaking up of  $\text{AgZn}_5$  into free zinc and  $\text{Ag}_2\text{Zn}_5$  causes the former to be more or less thrown out of solution, so that it floats up carrying with it some silver and lead.

The other alloy,  $\text{Ag}_2\text{Zn}_5$ , is characterised by being even less soluble in lead than pure zinc (relatively to the zinc present); so that when lead is saturated with silver and as much zinc as will form  $\text{Ag}_2\text{Zn}_5$ , there is less zinc present than the lead could take up were the silver absent. Moreover, the solubility of lead in  $\text{Ag}_2\text{Zn}_5$  is less than in mixtures of this alloy with either  $\text{AgZn}_5$  or free silver. Further, the alloy  $\text{Ag}_2\text{Zn}_5$ , when exposed to the air for a short time after freshly scraping or filing, assumes a peculiar coppery hue; the presence of small quantities of lead or bismuth does not prevent this action taking place, nor does the tint become much modified if a little surplus zinc or silver be present, although larger proportions greatly reduce the shade.

Identically the same conclusions as to the existence of the two compounds,  $\text{AgZn}_5$  and  $\text{Ag}_2\text{Zn}_5$ , also appear to result from the examination of the alloys formed on intermixing bismuth, zinc, and silver, in some respects in an even more marked way. The detailed description of these results, like that of alloys containing aluminium and other ternary mixtures, is reserved for another occasion.

In the case of alloys of lead, zinc, and silver, the curve representing the distribution of the silver between the heavier and lighter alloys formed resembles in general character that similarly obtained in the case of lead, zinc, and tin; at first, with small proportions of silver, the lighter alloy contains by far the larger quantity of silver; so much so, indeed, that only inconsiderable amounts are retained by the lead, practically the whole floating up with the zinc, whence, obviously, the utility of the zinc process for

desilvering argentiferous lead. But with mixtures richer in silver this behaviour is less marked; as the silver in the total mass increases, the difference between the silver percentage in the two alloys increases less and less rapidly, until finally a point is reached when the difference attains a maximum, after which the silver in the heavier alloy increases more rapidly than that in the lighter alloy, causing the difference to diminish again. In other words, the curve first rises from the origin extremely steeply, then at a less rapid rate, until a turning point is arrived at, after which the curve descends again towards the base line. With tin as the third metal the curve finally descends below the base line; but with silver the descent is not carried so far as this.

Precisely analogous results appear to be obtained with mixtures of bismuth, tin, and silver.—C. R. A. W.

#### Artificial Cryolite and the Dissociation of Aluminium Fluoride. A. V. Asbóth. Chem. Zeit. 14, 868—869.

THE chemical analogies of magnesium and zinc suggest the utilisation of the cheaper metal as a reducing agent for such purposes as the production of aluminium from the double chloride of aluminium and sodium, and from aluminium fluoride. Experimenting in this direction, the author fused together common salt, aluminium fluoride, and zinc in a porcelain crucible, exposing the mixture to a blow-pipe flame for 15 minutes. After cooling, the melt was extracted with hot water, leaving some metallic particles and a rose-coloured powder. In the aqueous solution were found the chlorides of sodium, aluminium, and zinc. In the metallic particles no aluminium could be detected, and the rose-coloured powder appeared to be cryolite. Starting a fresh experiment, and endeavouring to gain more intimate admixture by first fusing the sodium chloride and dropping in small portions of aluminium fluoride, the author observed an evolution of gas of chlorous odour to take place with each addition, and abandoning the attempt to prepare aluminium, confined his attention to this reaction. On extracting the melt with water as before, the same rose-coloured powder remained undissolved, and on analysis proved to be impure cryolite. The following equations represent the mode of its formation:—

The method of analysis of the crude artificial cryolite was as follows:—0.3—0.5 gm. was weighed into a platinum dish and heated to dryness with strong sulphuric acid, the mass was dissolved in dilute sulphuric acid, the aluminium precipitated with ammonia, and the filtrate evaporated to dryness, ignited, dissolved in water, filtered, evaporated, and weighed as sodium sulphate. The fluorine was determined as  $\text{CaF}_2$  by the method due to Fresenius. Sulphuric acid was present in the substance as an impurity, probably as basic aluminium sulphate. The results of two analyses, with all the sodium calculated to cryolite, are—

	I.	II.
	Parts per Cent.	Parts per Cent.
Cryolite ( $\text{Na}_6\text{Al}_2\text{F}_{12}$ ).....	42.52	42.51
$\text{Al}_2\text{F}_6$ .....	8.42	16.14
$\text{Al}_2\text{O}_3$ .....	38.21	39.84
$\text{Fe}_2\text{O}_3$ .....	7.38	7.38
$\text{SO}_3$ .....	4.03	4.15
	100.56	101.02*

\* 101.03 in original.

The analyses are of different specimens prepared differently, and in both cases without weighing the ingredients before fusion. More cryolite appears to be formed when zinc is present. The presence of alumina as shown

above may either be due to the oxidation of aluminium momentarily reduced by the zinc, or to the decomposition of aluminium fluoride by the oxygen of the air, in which case free fluorine must result. The impure artificial cryolite is amorphous, partially fuses into granules at a high temperature, and becomes white.—B. B.

*Aluminium in Iron.* H. M. Howe. Eng. and Min. Jour. 50, 213.

THE writer points out that the remarkable effect produced by the addition of a minute quantity of aluminium in enabling extremely soft ingot iron, very low in carbon, to be run into very thin and difficult castings, is not due to the lowering of the melting point. F. Osmond has shown that an ingot iron containing 0.10 per cent. of carbon and 5 per cent. of aluminium begins to melt at 1465°, only 25° lower than that of soft steel. All that aluminium can do, Osmond believes, "is to reduce the oxide of iron, make a thin slag, and so enable the purified metal to run more fluid." A sample of spiegeleisen, to which 3 per cent. of aluminium had been added, underwent a remarkable change, the characteristic broad tabular fracture gave place to a fine granular fracture resembling No. 3 pig iron. The analysis of the sample before and after the addition of the aluminium showed that the combined carbon had been reduced from 4.8 to 0.93 per cent. and that the graphitic carbon had increased from nil to 3.45 per cent. The effect of the aluminium in this case is therefore similar to that of silicon in driving the carbon out of combination, and is opposed to the action of manganese, which, like chromium, increases the solvent power of iron for carbon. The great change in its affinities, which aluminium seems to undergo rather rapidly at high temperatures, leads to the question whether, like iron, nickel, and cobalt, aluminium may not be found to possess a distinct critical point in which the specific heat changes abruptly, with accompanying marked thermal phenomenon.

Accumulating facts seem to indicate that the broad tabular fracture of spiegeleisen is not due directly to the presence of manganese, but to the large proportion of combined carbon which that manganese permits the iron to retain. For ferro-chrome, whose composition resembles that of spiegeleisen only in its high proportion of combined carbon, has a fracture almost identical with that of spiegeleisen. The high proportion of combined carbon in the cast iron for the basic Bessemer process whose fracture more closely resembles spiegeleisen the more carbon it contains, is probably chiefly due to the low proportion of silicon present; and as the lower the silicon the better the iron for the basic process, so it may be graded by its fracture, the best iron resembling spiegeleisen the most closely. A sample of pig with the characteristic spiegeleisen fracture contained 4 per cent. of combined carbon, 0.02—0.05 per cent. of silicon, and 0.20 per cent. of manganese, 2.7 per cent. of phosphorus, 0.03 of sulphur. A fact which may bear on the explanation of the Mitis process is that aluminium added to molten steel quieted the metal completely and caused it to pipe deeply. Little white specks were found on the surfaces, which proved to be alumina. The aluminium appears to reduce any iron oxide present.

*The Imperial Silver and Lead Works at Příbram.* A. Zdráhl. Jahrb. derk. k. Bergakademien, 1890, 38, 1; Chem. Zeit. Rep. 14, 185.

THE fire bridges of the furnaces used in roasting the ore have, until recently, been cooled by water. This is now done by a stream of air which is conducted through a cast-iron conduit in the fire bridge. The air emerges from this at a high temperature and is passed into the fire, thus producing a higher temperature than if cold air were used. If the fire bridge is coated with magnesia, less repairs are needed. Care is taken to allow none of the fumes to escape, they being condensed in long flues. Flue dust, ash, and rich marl is used as a flux in roasting the ore. The sulphur is reduced on an average from 12 per cent. to 0.9 per cent. The lead ore is roasted in open kilns built of slag. As the

slag if untreated would fly on heating, slag bricks are prepared by melting the slag and mixing this with angular pieces of old slag and pressing into shape. The furnace charge is usually 10 t. roasted ore, 12 t. of slag, 1 t. of tuff, 1 t. of roasted lead metal, 2.9 t. of dross (litharge and such like), 1.4 t. of lime, 0.4 t. of cinder, 0.3 t. of cast iron, 1.5 t. of finery slag. 1,300 kilos. of this charge requires 150 kilos. coke, and 4 h.l. of charcoal, or 120 kilos. coke and 6 h.l. of charcoal, and usually 24 charges are made every 24 hours. The slag contains 28—30 per cent. of silica, 36—37 per cent. of ferrous oxide, 9—11 per cent. of lime, 4—5.5 per cent. of alumina, and 9—10 per cent. of zinc oxide, and usually not less than 2 per cent. of lead, and 0.025 per cent. silver. The lead metal contains 41 per cent. iron, 11 per cent. of lead, and 11 per cent. of zinc. In the cupellation furnace a marly bottom is made over the ordinary bottom and only the first is replaced for a fresh cupellation.

The loss of metal is given in the following table on 100 parts ore (a) and on 100 parts finished metal (b).

Lost in	Silver.		Lead.

*On the Amount of Phosphorus in Wrought Iron.* A. Ledchur. Stahl. u. Eisen, 1890, 10, 513.

AN equal amount of phosphorus is injurious to a different degree in different irons, being much more so to ingot iron, which cannot stand more than 0.2 per cent., than to wrought iron, which may contain up to 0.4 per cent. This is probably partly because the latter contains 0.1 per cent. in the slag which exists in the metal. In the case of steel rich in carbon, which is in itself often *short*, the presence of phosphorus must be particularly injurious.

On the other hand, there are many irons, such as that prepared by the Clapp-Griffiths process, which are proportionally unaffected by phosphorus, so that it cannot be said that with our present knowledge we are able to correctly estimate its effect.—A. L. S.

*The Action of Zinc on Dilute Sulphuric Acid.* F. Pullinger. J. Chem. Soc. 1890, 815—827.

THE results proved are as follows:—

1. Pure zinc with a perfectly smooth surface is not acted upon by dilute sulphuric acid which has been submitted to prolonged boiling.
2. Pure zinc with a rough surface is readily acted on, but in a less degree, by acids which have been boiled than by those which have not.
3. Oxidising agents, such as electrolysed sulphuric acid, hydrogen peroxide, and nitric acid, increase the rate of dissolution.
4. A reducing agent, such as hydriodic acid, almost entirely prevents solution, but those containing sulphur, such as sulphur dioxide, are without effect.

5. It is not improbable that when zinc with a rough surface dissolves in dilute sulphuric acid, persulphuric acid, acting catalytically, is the cause of the dissolution.

6. In all probability, pure dilute sulphuric acid would, at ordinary temperatures, be entirely without action upon metallic zinc, whether the surface of the latter were rough or smooth.

*On the Action of Sulphurous Acid on Metals.* J. Uhl. Ber. **23**, 2151—2154.

See under XXIII., page 970.

*The Metallurgical Treatment of Cupriferous Pyrites in the District of Huelva.* L. de Launay. Annales des Mines, 1889, XVI. 427; Proc. Inst. Civil Eng. **101**, 374.

THE author, after describing the geology and structure of the great pyrites mines of San Domingos, Tharsis, Rio Tinto, and others, proceeds to consider the methods adopted for exhausting the copper. These are classified as follow:—

1. Natural cementation.
2. Artificial cementation.
3. Artificial cementation with chlorides.

The first of these methods, which is essentially one of atmospheric oxidation, is practised at San Domingos, in Portugal, where the burning of pyrites in open heaps is forbidden by law. The ore, a cupriferous iron pyrites containing from 2.5 to 3.0 per cent. of copper, is broken into lumps of the size of the fist, and spread out on floors in heaps varying from 15 to 40 ft. in thickness. Deep trenches are cut through the heap at regular intervals for the escape of drainage water, and a series of holes lined with earthenware pipes are sunk into it at the top, for the purpose of inserting thermometers when it is desired to ascertain the temperature in the interior. Water is distributed over the surface by a rectangular network of pipes with jets, and the operation is continued for several years, about 3,000,000 tons being under treatment at one time. The sulphates formed by the joint action of air and water dissolve in the latter, and are collected in channels leading to the cementation tanks. The surface of the heap is broken up by a pick from time to time to prevent the crust of sulphates from becoming compact and impermeable to water. The operation, though extremely simple in principle, requires somewhat delicate management, especially in regard to temperature. If the heap is too cold the sulphide of copper is not attacked, while if too hot, an excessive production of steam prevents the access of air and the consequent oxidation of copper, while a larger proportion of iron is dissolved. The best results are obtained at 100° F., a heat that is maintained by varying the amount of water. It is also essential that the solution shall be as rich in copper sulphate as possible, and if the liquors are too poor, the watering of the heap is sometimes suspended from 15 days to a month.

When the proportion of copper in the heap is reduced from 2.8 to 0.25 per cent., the heap is broken up and exported for use as a sulphur ore, the process having the advantage of saving the bulk of the sulphur. The quantity of water required being very large, two storage reservoirs have been built for holding it, one being of 5,000,000 and the other of 1,500,000 tons capacity, the latter serving also for irrigation and domestic supply.

The liquors obtained from watering the heaps are led into the cementation tanks, which are asphalted basins 13 ft. square, arranged in 10 series of 24. These are filled with pig iron piled ehequewise, and the coppery liquors are run through them in such a manner as to obtain the most complete precipitation with a minimum consumption of pig iron. The precipitated copper or *casera* deposits on the surface of the pigs, and is cleaned off at intervals of a month. The deposit, consisting of a mixture of copper with graphite, and iron rust, containing about 65 per cent. of copper, is dried upon a heated surface and packed in bags of 100 lb. for export.

The consumption of pig iron, which theoretically should be only 0.83, is actually 2.0 per unit of copper obtained.

This is due to the formation of ferric sulphate in the liquors, which must first be reduced to ferrous sulphate by the iron, before any copper can be separated.

The exhausted liquor, essentially a ferrous sulphate solution, is stored in tanks, which, to avoid permanent poisoning of the river, are only emptied during the period of spring floods.

*Artificial Cementation.*—This term is applied by the author to the method of burning the pyrites in heaps as a preliminary to extraction by water and precipitation, which is in general use in Spain, although at present attempts are being made to abolish it on account of the damage done by the sulphur gases. At Lagunazo, near Tharsis, where the ore contains from 2 to 3 per cent. of copper, with about 3 per cent. of arsenic, 2.3 oz. of silver, and about 1½ dwt. of gold per ton, it is burnt in heaps called *teleras*, in a similar manner to that subsequently described as in use at Rio Tinto, for about two months.

The solution of the copper is effected in two stages, it having been found that ferric sulphate liquors will remove from one-eighth to one-fifth of the copper in the first 10 days. The burnt ore is subjected to a first washing in tanks for 12 hours, followed by a second of 24 hours, and a third of 48 hours, after which it is piled into heaps called *terrerros*, where the residual copper is extracted by watering, an operation which, like that in the natural cementation process, lasts for several years. The cementation is effected in tanks, through which a very rapid current is maintained, the iron being turned out every 10 days; the amount of iron consumed is 1.7 per unit of copper obtained. The *casera* when dried and roasted in a reverberatory furnace, an operation which requires about 4 per cent. of its weight of coal, is packed in bags for export.

The deposit at Lagunazo was only opened in 1882. It now produces about 120,000 tons of pyrites annually. About 1,000 tons of copper are obtained from 80,000 tons of burnt ore under treatment.

*Artificial Cementation with Chlorides.*—In this method, which is practised at Rio Tinto, the copper is dissolved, not as sulphate, but as chloride. This has the advantage of reducing the waste of iron in the precipitation tanks, by avoiding the formation of ferrous and ferric sulphates, as the solution of the sulphide of copper is effected by means of ferric chloride, while iron pyrites is but slightly acted on. By this means a ton of copper precipitate may be obtained with an expenditure of an equal weight of pig iron.

The produce of the mine is divided into five different classes, each having its own method of treatment. These are:—

1. Smalls, obtained by sifting the larger sizes. These are subjected to a modification of Doetsch's process of washing by ferric chloride, as they pack too close to be converted on sulphates by atmospheric oxidation.

2. Ordinary ores with less than 2.75 of copper. These are burnt, watered, lixiviated, and precipitated.

3. Ores of 3.75 and 4 per cent. average, obtained when necessary by the mixture of other kinds. These are sent by rail to the pier at Huelva and shipped, those of 3.75 per cent. going to England, and those of 4 per cent. to Germany.

4. Rich ores above 6 per cent. These are unfit for calcination, and are therefore smelted for regulus in water-jacket cupolas.

5. Minerals containing copper and lead. These are put aside as giving trouble in the ordinary working, and have not as yet been utilised.

*Treatment of the Smalls by the modified Doetsch Process.*—This, which like the method of natural cementation at San Domingos, does away with roasting, but reduces the loss of time and iron by adding salt, is applied in practice with the following modifications:—

On the side of a hill below the *teleras*, or roasting heaps, there are five series of tanks, each series consisting of seven tanks 15 metres long, 4 metres wide, and 1½ metres deep, which are divided into eight compartments by walls of perforated bricks, placed edgewise and covered by planks. At a lower level is placed another series of four larger tanks, 100 metres long, 2 metres broad, and 1½ metres deep.

The whole are used indifferently for the treatment of the smalls, and for the first washing of the burnt ores, which extracts about one-fifth of their contents of copper, before sending them to the *terreras* at Naya. The raw smalls are mixed with a proportion of burnt ore in lumps of the size of a walnut, and washed with liquors brought from the large *terreras* containing a certain quantity of common salt. This operation lasts about eight days; the wash-water going to the precipitation tanks, while the partially exhausted mineral is taken to the *terreras* at Naya. The reactions in this method appear to be as follows:—

The burnt ore having been subjected, at a high temperature, to the action of oxygen and chloride of sodium, gives rise to—

The chlorine liberated, acting on the sulphides of iron and copper, produces ferric and cupric chlorides. There are therefore present  $\text{FeSO}_4$ ,  $\text{Fe}_2(\text{SO}_4)_3$ ,  $\text{CuSO}_4$ ,  $\text{Fe}_2\text{Cl}_6$ , and  $\text{CuCl}_2$ , with an excess of salt which changes the ferric sulphate into chloride. The copper in the ore, existing partly as cuprous sulphide  $\text{Cu}_2\text{S}$ , and partly as cupric sulphide  $\text{CuS}$ , the reactions become—

the ferric chloride attacking and dissolving the copper, while the iron pyrites is almost untouched. The final separation of the copper is effected by cementation in the manner previously described.

#### *Treatment of Ores with less than 2.75 per Cent. of Copper.*

—This, the method of artificial cementation with chlorides, is applied to the largest part of the output of the mine. It includes the four operations of roasting, washing, precipitation, and cleaning of the precipitate, or *cascara*.

The roasting is performed in *teleras*, which are heaps of a truncated pyramidal form, 3 metres high, on a base of 6 by 8 metres for those of 800 tons, and 9 by 8 metres when containing 1,200 tons. At the bottom, one transverse and three longitudinal flues, about 20 in. square, are formed by the larger blocks of mineral. These are the firing passages, and communicate with vertical chimneys, of which there are two in the 800 ton, and three in the 1,200 ton heaps. The mass of the heap is made up of lumps a little above nut size, salt being added in the proportion of 14 tons to 800 tons of pyrites. When the fire has been started with a little wood, it is kept up by the heat of the burning sulphur. It is essential that no rich ore shall be included, as, on account of the action of "kernel roasting," lumps of rich sulphide of copper are formed, which cannot be subsequently dissolved; and as the mass of material is so large that hand-picking is not easy, great loss of copper is likely to ensue. It need scarcely be said that the operation causes an enormous nuisance, as, since the introduction of the use of salt, the volatile products contain chlorine as well as sulphurous acid, and, especially during the prevalence of easterly winds, the village of Rio Tinto is almost uninhabitable from the sulphur smoke, while all vegetation is destroyed to a distance of six leagues around. This is now sought to be mitigated by removing the roasting heaps to a greater distance—at Planes, where large lead chambers are under construction for the purpose of saving from the sulphur gases the sulphuric acid required for cleaning the copper precipitate, and which has hitherto been purchased abroad. A more important application has, however, been found in using sulphurous acid gas for promoting the formation of sulphates in the ore, which is now carried out on a very extensive scale at Naya.

In this method, the *teleras* made in the ordinary way, as soon as they begin to give off sulphurous acid, are covered up with a fresh quantity of mineral, partly raw and partly calcined, to which 2 or 3 per cent. of salt, and a similar proportion of peroxide of manganese have been added. The whole is formed into a heap 8 in. high with a flat top, which is divided by gutters into squares of 8 metres in the side. The remaining operations are effected in the usual way, the *teleras* being watered at intervals for months and years, the

copper being slowly dissolved, and collected at the bottom of the heap. It is necessary to break up the surface with a pick at intervals, to prevent its becoming impermeable to water.

The sulphurous acid gas in this modification of the process, in the presence of steam formed by the heat developed in the heap, produces sulphuric acid, which acts upon the oxides in the crust of the roasted minerals. The salt and manganese ore may, jointly with the sulphuric acid, evolve chlorine, forming ferric chloride, which decomposes the sulphides of copper and silver. It is also possible that, under the action of heat and sulphuric acid, oxygen is evolved, which acts directly upon the pyrites.

The precipitation of the copper is effected at La Cerda, near Rio Tinto, in a series of tanks 100 metres long and 30 metres broad, divided into 10 parallel series, receiving a uniform supply. The total length is about 400 metres, with a difference of level of 4 metres, giving a sufficiently rapid flow. Pig iron as run from the furnace and scrap are used, the latter being put into baskets. Every 10 days the iron is removed, and, after scraping to collect the deposited copper, is returned to the tanks. The consumption is reduced to a little more than 1 ton of pig iron per ton of precipitate produced.

The *cascara* precipitate as collected is very impure, containing only 65 to 70 per cent. of copper, the remainder being ferric oxide, more or less arsenical, graphite from the pig iron, silica, &c. After treatment with water acidulated with sulphuric acid, which dissolves the basic ferric arseniates without touching the copper, it is passed over sieves of  $\frac{1}{16}$  in. mesh to separate any adherent masses of cast iron, which are hand-picked, and any copper separated is subjected to another washing with acid. The *cascara* passing through the sieves is washed in a current of water, where it separates the order of density into *cascara*, or copper; *grafita*, or particles of coal and graphite; and *pucha*, a fine black sand. The *cascara* is subjected to a fresh washing upon a fine wire-gauze screen, which separates a further quantity of graphite, and this passes to a series of plunger jiggling machines, where it is finally cleaned. The graphite is collected and returned to the rich ore smelting furnaces.

The *pucha* is washed upon convex round buddles 15 ft. in diameter, by which a certain quantity of fine copper is saved. The waste is made into balls, which are dried in heaps and also sent to the smelting furnaces.

The silver in the pyrites usually remains in the *terreras*, a small proportion only passing into the copper precipitate.

The rich ores containing more than 4 per cent. of copper are, after burning, smelted in cupolas or water jacket furnaces of an American pattern, having a large exterior fore-hearth or receiver in which the separation of slag and regulus takes place. The charge consists of burnt ores, old slags, a certain proportion of raw pyrites, quartz, and graphite. The regulus, which is exported to England, contains from 38 to 40 per cent. of copper; the slags with 0.4 per cent. are thrown away.

#### PATENTS.

*Improvements in Apparatus for Deoxidizing, Dephosphorizing, Desulphurizing, and Treating Iron and other Ores, and for Collecting and Burning the Fumes and Gases therefrom.* M. R. Conley, Brooklyn, and J. H. Lancaster, New York, U. S. A. Eng. Pat. 8678, May 24, 1889. 8d.

The process is carried out in a series of cylindrical retorts placed in a furnace. The retorts are filled through vertical pipes arranged in a line, so that they may be charged successively from a suitable hopper travelling on rails. Each of the retorts is provided with a discharge chute, which extends through the rear wall of the combustion chamber, and their lower ends are approximately upon a level. The contents of the retorts may be discharged directly into an open-hearth furnace or into an air-tight box, and, when sufficiently cooled, mixed with pitch, so as to withstand exposure to atmospheric air. To desulphurise, &c. the ore, air, hydrogen, or other gas may be admitted by suitable means, and the fumes conveyed to a gasometer, and

thence to the furnace for heating the retorts. Each of the retorts is provided with a rotary stirrer, extending longitudinally. The shafts of these stirrers have bearings at their rear ends in sockets. Outside the front ends of the retorts the stirrers have secured upon them sprocket wheels. Upon this sprocket wheel moves a sprocket chain extending about the sprocket wheels and also about a suitable pulley. The sprocket wheels are so arranged that the sprocket chain, as it passes to and fro, will engage with the teeth on the wheels, and will cause all the stirrers to rotate in unison. In order to discharge the sprocket chain from any one or more of the wheels, levers are fulcrumed on the front of the combustion chamber upon the bent arm of which are attached friction rollers. The chain passes between these rollers, so that by raising the lever the chain is raised above the wheel, which is thrown out of gear. The shafts of the stirrers have teeth curved longitudinally, and are wider at their free ends. They are also provided with longitudinal strengthening ribs. At the ends of the teeth there are formed on them horizontally-extending flanges, through which extend transverse apertures. The teeth extend radially from the shaft in three directions, certain of the teeth being in line with each other, and the others at right angles, so that in discharging, the teeth may be turned so as not to obstruct the bottom of the retort. Each retort is provided with a scraper, which, when not in use, is braced against the end of the retort. It is released from outside, and can be moved freely inside the retort, without admission of air.—J. B. C.

*Improvements in and connected with the Utilisation of Sulphate of Iron Galvanising Pickle.* T. Parker and A. E. Robinson, Wolverhampton. Eng. Pat. 10,554, June 29, 1889. 4d.

The waste pickling solution is evaporated in contact with iron in order to neutralise any free or uncombined acid to a specific gravity of about 1.4 or 1.5. "The evaporation is preferably conducted in iron vessels in which scrap iron or iron borings or turnings are contained, and by means of artificial heat. To the concentrated neutral pickle thus obtained, is then added a sufficiency of strong sulphuric acid to precipitate the iron. The supernatant solution may be drawn off or otherwise separated, as is well understood, and employed in the preparation of a second pickling solution, or be otherwise utilised. The precipitate consists of anhydrous sulphate of iron, and this is distilled and manufactured into fuming or Nordhausen sulphuric acid in the ordinary manner."—J. B. C.

*Improvements in Roasting certain Ores in order to obtain Metals therefrom, and in Means or Apparatus employed therein.* S. Trivick, London. Eng. Pat. 11,882, July 26, 1889. 8d.

THIS invention relates to the construction of a furnace to effect the roasting of ores sufficiently rich in sulphur to support combustion without additional fuel. This furnace contains a series of hearths superposed one above another upon a bed. These hearths are formed of firebrick, communicating by openings with the one above and the one below. The top hearth is arched over, the arch containing an opening for the admission of the ore. At the front of each chamber is a door, adjustable in its position so as to admit more or less air, and for the introduction of rakes for moving the ore from floor to floor. "At each of the sides of the chamber is an opening, preferably towards the front, through which heated air enters and aids combustion of the sulphur;" and "this air is conducted and heated in its conduction by means of passages carried along the side and up over the fire chamber, joining other passages leading down behind, and then in front under the bed or through it to the front of the furnace. The products of combustion of the sulphides pass through the series of chambers and away from the uppermost by openings leading to a middle flue passage below a heating chamber," and then to the

stack. "The heating chamber provided rearward of each furnace and over the flue chamber, serves, when packed with sand, to contain tubes suitable for heating leaching or other fluids used in the subsequent treatment of the ores."

—J. B. C.

*Improvements in the Production of Aluminium and in Apparatus employed for that purpose.* H. Bessemer, jun., Westend. Eng. Pat. 12,033, July 29, 1889. 8d.

THIS invention consists in the use of combustion under pressure in order to secure a temperature sufficiently high to effect the reduction of aluminium oxide by carbon or gaseous hydrocarbons, and in a method of rapidly cooling the aluminium vapour produced, by allowing the gaseous products to issue through a small aperture into a second chamber where they expand and become cooled. A mixture of aluminium oxide and carbon is made into briquettes, and is charged into a strong iron vessel having a refractory lining and cooled externally by means of water. Air, previously heated by a regenerator, and gaseous fuel are forced in at a pressure of 3 or 4 atmospheres with the result that a very high temperature is produced attended with the reduction of the alumina. The aluminium vapour and products of combustion escape at the further end of the vessel through a small fireclay tube, whose size is so adjusted that the pressure in the combustion chamber is not impaired by an undue escape of the gases. The rate of flow of the latter is further controlled by an adjustable plug which partially closes the end of the tube. The gases escape into a cooling chamber communicating with the atmosphere. The aluminium condenses and the products of combustion pass onwards.—H. K. T.

*An Improved Process of and Apparatus for Galvanising Metal Strips or Ribbons, Wire, and the like.* N. Vilart, London. Eng. Pat. 14,297, September 10, 1889. 8d.

THE ribbons or wires are drawn successively through a solution of potash, dilute acid, molten zinc, and water, being in each instance made to dip into the bath by passing over rollers and under drums. After leaving each bath they are passed through two cushions or bolsters of linen or asbestos, which clean them from the material of the one bath before passing into the next, and which, in the case of the zinc, regulate the thickness of the adherent metal. "As pure zinc is not sufficiently fusible it is generally mixed with about 5 per cent. of tin." The galvanised strips are, by this process, rendered capable of corrugation, or of manufacture into flexible metallic pipes, without the zinc stripping off. Seven drawings are given in the specification showing the arrangement of the appliances.—A. W.

*Apparatus and Process for Condensing the Metallic Vapours produced in Zinc Furnaces, and Furnace applicable in Combination with the said Condensing Apparatus.* E. Grützner, Loslau, and O. Koehler, Czernitz, Germany. Eng. Pat. 15,245, September 27, 1889. 8d.

THIS apparatus consists of a sheet-iron condensing chamber and a zig-zag settling chamber, open at the bottom, both submerged in water. The retorts are hermetically connected with the condensing chamber, in which a partial vacuum is produced by pumping out a portion of the water with which it is at first filled. The vacuum is afterwards maintained by connecting the exit end of the settling chamber with the furnace or its chimney. A furnace is described containing a battery of four or six vertical retorts surrounded by spaces for the circulation of furnace gases. The retorts are charged from the top, the residue after distillation being removed by detaching the bottoms of the retorts, which are held in position by clamps.—H. K. T.

*Improvements in the Manufacture of Alloys of Nickel with other Metals.* H. Marbeau, Paris, France. Eng. Pat. 16,318, October 16, 1889. 6d.

THE purpose of this specification is the production of an alloy of nickel, iron, and manganese, containing carbon, which is therein called "nickelo-spiegel," to be used to convert iron into ferro-nickel or steel-nickel. It is prepared by reducing together nickel, iron, and manganese ores, the following proportions being given as an example:—

Nickel ores (10 per cent. of Ni).....	2 tons.
Iron ores (50 per cent. of Fe).....	12 cwt.
Manganiferous iron ores (10 per cent. of Mn and 40 per cent. of Fe) .....	1 ton.

—A. W.

*Process for obtaining Salts of Thorium, Zirconium, and like Metals from their Ores or from Waste Residues of Hoods used for Incandescent Gas Lighting.* O. Imray, London. From W. MacKean, Paris, France. Eng. Pat. 16,555, October 19, 1889. 6d.

See under VII., page 941.

*A New or Improved Universal Furnace for the Fusion and Refining of Metals, Alloys, Dross, by the Dry Process or otherwise.* J. B. Alzugaray, Porto, Portugal. Eng. Pat. 16,776A, October 24, 1889. 8d.

THIS is a vertical furnace of octagonal shape having a crucible at its centre. The latter is provided with a discharge pipe and with a hopper passing through the top of the furnace.—H. K. T.

*Improvements in the Treatment of Waste Pickle from Galvanising Works and other such like Acid Liquors, and in the Apparatus employed therefor.* T. Turner, Birmingham. Eng. Pat. 17,074, October 29, 1889. 8d.

THE acid liquor is evaporated in an open roaster, the bed of which is made in the form of a shallow basin. The liquor is fed in this as fast as it is decomposed. After the liquor has attained a pasty condition, it is conveyed to the hottest (dull red) part of the furnace, where the iron chloride in contact with air and the acid vapours yields iron oxide and hydrochloric acid; this is condensed and used over again for galvanising purposes.

In order to render the furnace liquor-tight, a layer of sulphur, puddle, asphalt, &c. is inserted a few courses above the ground-line. In starting the furnace the liquor will permeate in the brickwork and cement it, and in the course of evaporation a protecting layer of iron chloride will be formed on the furnace bed. (See also this Journal, 1890, 809.)—H. A.

*Improvements in Apparatus for Separating Precious Metals by Amalgamation from Ores or Materials containing them.* R. E. Shill, London. Eng. Pat. 20,017, December 12, 1889. 8d.

THE apparatus consists of an inverted funnel-shaped vessel, whose base is perforated with holes, into each of which a short tube is fixed. These tubes pass under the surface of mercury contained in the base of another but larger conical vessel which surrounds the smaller one and at the top of which there is an outlet pipe. The pulp enters the tube of the inner vessel, passes downwards through the small tubes, through the mercury upwards into the annular space between the two vessels, and out at the exit at the top of the outer one. It is stated that the materials being thus forced under the surface of and through the mercury the float gold will be caught. The sulphides do not accompany the tailings, but fall on to the surface of the mercury, whence they are gradually worked by the agitation of the same into an annular space around the base of the outer vessel provided for the reception of them. The tailings, if they contain

gold, are passed through another similar vessel, or through another contrivance based on the same principle of forcing the materials through liquid mercury.—A. W.

*Improved Process for Separating Tin from other Metals more particularly applicable for the Treatment of Tin Plate Scrap and old Tinned Cases.* I. Bang, and A. Rudlin, Paris, France. Eng. Pat. 70, January 2, 1890. 6d.

THE tin is dissolved by means of caustic soda or potash lye, in presence of sodium nitrate or a suitable oxidising agent, the object of the latter being to hasten the solution of the tin by removing the film of hydrogen, formed by the reaction, from the surface of the material treated. The lye should be of a strength of 15° B., and should contain a proportion of nitrate largely in excess of the quantity needed to dissolve the tin and required by the following equation, given by the patentees as representing the reaction—

Caustic soda and ammonia are thus obtained while the tin is in solution as sodium meta-stannate. By the addition of bulk of lime, calcium meta-stannate is precipitated, and the clear alkaline solution is ready for use again.

Pure metallic tin is easily obtained by fusing the calcium meta-stannate with carbon and a flux.—O. H.

*Improvements in and connected with Furnaces for Recovering Tin from Tin Slag.* J. Letcher, Devonan. Eng. Pat. 5608, April 14, 1890. 6d.

ACCORDING to this invention the furnace in which the tin slag is smelted consists of a vertical chamber constructed of fireclay, bricks, or other suitable material. Air is admitted to the furnace through apertures provided in the walls at a convenient and suitable height from the base. Below the level of the air apertures and between them and the base is an aperture which, while the melting process is in progress, is blocked by fireclay. At intervals, the fireclay blocking the aperture is pierced and the metal run out through the hole made therein. At the top, the furnace communicates by a throat with a long horizontal flue, which communicates with a chimney stack. "By the employment of a long horizontal flue communicating with a stack, a draught is maintained sufficiently powerful to melt the metal in the furnace without the waste of coke, employed as fuel, obtaining in furnaces, where a blast or jet of steam is directed into the furnace." The long flue also serves as a means for receiving particles of metal deposited from the fumes passing through the flue on the way to the stack.—J. B. C.

*Improvements in Converters.* A. J. Boulton, London. From J. W. Bookwalter, Cologne, Germany. Eng. Pat. 5894, April 18, 1890. 8d.

IN order to reach the highest results in the rapid mode of conversion, the air blasts should be so applied to the metal in the bath that the returning currents of metal shall not be upon the surface towards the tuyeres, for the scoria floating upon the surface of the metal would thus be drawn with these return currents into the area of violent agitation, and become remixed with the metal. The returning currents of metal must be drawn from a comparatively quiescent body of metal, and from such a depth below the surface that there shall be no tendency to carry with the metal any of the impurities formed in the process.

This is attained by applying a series of tuyeres at one side only of the metal in the bath, arranged in a straight line and parallel with each other, so as to act upon the metal, near the surface or, instead of a series of tuyeres, one continuous sheet of the air blast corresponding to the width of the metal in the bath may be applied.

By this arrangement, surface currents in the metal are avoided, which tend to carry the floating scoria back to the mouth of the tuyeres and to mix together metal and scoria

In order to renew the tuyeres and lining, which are rapidly corroded, the converter is constructed of two parts, the upper portion being fixed or attached to trunnions, and the lower being detachable and containing the metal bath and tuyeres. The arrangement is shown in drawings attached to the specification.—J. B. C.

*An Improved Process for Treating Copper and its Alloys to prevent Oxidation and Decoloration thereof during Heating or Annealing.* H. H. Lake, London. From G. W. Cummins, Vienna, U.S.A. Eng. Pat. 8989, June 10, 1890. 8d.

This process consists in heating or annealing copper in a closed vessel filled with inert gas. The vessel consists of a horizontal tube closed with a plug at one end and communicating at the other end by means of an elbow-piece with a vessel of water. The vessel is first filled with steam or other inert gas, the copper articles are then introduced, and when sufficiently heated are raked into the cooling liquid. By this means oxidation is prevented, a matter of importance when dealing with copper wire required for electrical purposes. The use of this apparatus also prevents the reduction of oxides of arsenic and antimony which are generally present in copper. Those oxides frequently become reduced when copper is heated to a high temperature in contact with products of combustion, and render the metal brittle.—H. K. T.

*Improvements relating to the Manufacture and Treatment of Iron and Steel, and to Compounds for use therein.* H. H. Lake, London. From J. D. Brown, New York, U.S.A. Eng. Pat. 8991, June 10, 1890. 4d.

This is a compound for welding, toughening, or refining steel, and consists of "borax 33 parts, pumice-stone 8 parts, salt 1 part, sal-ammoniac 3 parts, dolomite 1 part, and spathic iron ore 1 part, proportions by weight." It may also be used for producing a high-grade steel by adding it to the molten metal. Venetian red or carbonate of iron may be used instead of spathic iron ore, ordinary limestone instead of dolomite, and silica sand in lieu of pumice-stone. The essential ingredients are borax, sal-ammoniac, pumice-stone and dolomite.—H. K. T.

*Improvements in the Reduction of Iron Ores.* H. W. Lash and J. Johnson, Pittsburgh, U.S.A. Eng. Pat. 8992, June 10, 1890. 6d.

The improvement relates to the direct reduction process, by which the loss of iron is reduced to less than 4 per cent. of the amount present. The ore and coke are separately pulverised and passed through a quarter-inch screen. The former is then mixed with 20 to 30 per cent. of its weight of the latter, and the whole is thoroughly ground with a sufficient quantity of water, oil, or other suitable fluid to form a pasty mass. This grinding is the chief point of the process. The finely-ground pasty mixture is spread on the hot hearth of the furnace and covered with a layer of pulverised carbon. As reduction takes place the mass swells, and it is maintained that as a result the fused slag escapes through the pores of the sponge on to the furnace bottom, whence it is tapped off, thus giving a purer metal than is otherwise obtained. The reduced iron is balled up and treated in any suitable manner.—A. W.

## XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

*The Passive State of Iron and Steel.* Part I. T. Andrews. Proc. Roy. Soc. 48, 116—126.

The author has studied the effect of magnetism on passive steel in respect to its behaviour with strong nitric acid, both cold and hot, by measuring the E.M.F. produced by two bars of the same steel, one magnetic and the other not so, immersed in the acid. The apparatus was arranged as in the following sketch:—

THE PASSIVE STATE OF IRON AND STEEL.

The polished bars were  $8\frac{1}{2}$  in. long and 0.261 in diameter, and each was placed in one limb of the U-tube containing  $1\frac{1}{2}$  fluid ounce of nitric acid of sp. gr. 1.42. The bar A was sometimes magnetised beforehand and sometimes by the coil C, in which latter case any results obtained were due to residual permanent magnetism. Results are given of the measured E.M.F. at the time of immersion, and at intervals extending in some instances over seven days. In some cases at the moment of immersion an instantaneous but steady deflection of the galvanometer took place, indicating an electro-positive position for the magnetised bar, but this subsided in a few seconds, and did not interfere with the results due to electro-chemical action. These results show that magnetism of low intensity and even of high intensity, whilst modifying to a limited extent, does not entirely overcome the passivity of steel in cold nitric acid.

The effect, however, is quicker when the acid is warm. A somewhat similar apparatus was placed in a beaker of water which was gradually heated, and the observations were taken at different temperatures up to the transition point from the passive to the active state, which averaged  $195^{\circ}$  F. The acid remained colourless until a temperature of  $100^{\circ}$  to  $120^{\circ}$  F. was reached, when a very pale yellow tint was perceptible in both tubes. Very little solvent action took place, however, until the critical point was reached, indicated by the explosive evolution of red fumes. This happened first in the limb containing the magnetised bar, the first intimation of the passivity of the steel having been overcome being a sudden and extensive deviation of the galvanometer indicating electro-positive for the magnetic bar. The E.M.F. at this point was very high, being from  $\frac{1}{10}$  to  $\frac{1}{5}$  of a volt. After this the steel became partially passive again for a short time. Unless the critical point was reached the steel never fully lost its passivity but was only very slowly and partially acted on by the acid.—A. W.

*The Oxidation of Metallic Sulphides by the Electric Current.* E. F. Smith. Ber. **23**, 2276—2283.

See under XXIII., page 971.

#### PATENTS.

*Improvements in Galvanic Batteries and Electro-Chemical Accumulators.* R. E. B. Crompton and D. G. Fitzgerald, London. Eng. Pat. 5159, November 25, 1881. (Third Edition.) 6d.

In order to obtain a porous electrode presenting great surface to the action of the electrolyte an alloy of lead and some suitable metal such as sodium, potassium or zinc, or a mixture of lead with a material such as chalk, manganese dioxide, &c. is formed into the desired shape, and then subjected to the action of water, acid, or other suitable liquid which is capable of dissolving out all the material with which the lead is mixed, leaving a porous lead plate. Electrolysis may also be used for the removal of the foreign matter.—B. T.

*Improvements in Effecting the Separation of Gold from Antimony.* T. C. Sanderson, Oporto, Portugal. Eng. Pat. 6882, April 24, 1889. 6d.

This invention consists in separating by electrolysis, gold from antimony obtained in smelting auriferous antimony ores. For this purpose the antimony containing the gold is placed in a bath of a suitable salt of antimony and connected with one pole of an electric generator to serve as a positive electrode. To the other pole is connected a plate of suitable conducting material such as carbon or antimony to serve as negative electrode, and a current of electricity is passed through the bath, the antimony plate being dissolved leaving a mud containing most of the impurities originally present in the plate and practically the whole of the gold present. Metallic antimony will at the same time be deposited upon the negative electrode from the bath or electrolyte. The auriferous antimony ore is smelted and pickled in hydrochloric acid or sulphuric acid to get rid of sulphide of iron if present. The electrolysis bath is made up of chloride of antimony formed by dissolving the powdered ore in commercial hydrochloric acid. This is diluted with strong brine in the proportion of 1 measure of chloride of antimony containing 35 per cent. of the salt to 3 measures of saturated brine. The plates of auriferous antimony are placed in this solution and connected with the electric generator. The other pole is also connected and a current of 5 volt passed through the solution. To collect the auriferous mud and keep up free circulation of the bath, the negative electrodes are enclosed in rectangular wooden frames on both sides of which porous material such as calico, flannel, &c. is stretched. The muddy liquid resulting from the solution of the plates attached to the positive electrode is drawn off from the bottom of the bath, passed through a filter, and again introduced into the vessel through the top of the frames containing the negative electrodes. Instead of making a bath by adding chloride of antimony, brine acidified with hydrochloric acid may be used. On the passage of the current, the antimony on the positive electrode will dissolve and form chloride of antimony.

—J. B. C.

*Improvements in Lead Tanks and in the Method of Manufacturing the same.* P. J. Davies, London. Eng. Pat. 12,157A, July 31, 1889. 8d.

This describes an arrangement of cores and moulds for casting lead tanks or cisterns suitable for storage batteries and other purposes; an arrangement of wooden stays and runners may be used for strengthening purposes.—B. T.

*Improvements connected with or Applicable to Baths or Vessels containing Liquids used in Electro-plating or Dyeing, or the Electrolyte of Storage Batteries, and the like.* E. Hopkinson and D. Appleton, Manchester. Eng. Pat. 14,871, September 20, 1889. 6d.

To obtain uniform density of the liquid used in dye-works, electro-depositing baths, electric accumulators, &c., perforated pipes are laid along the bottoms of the vessels, and air or other suitable gas is pumped through these perforations to produce circulation of the liquid.—B. T.

*Improvements in Methods of and Apparatus for Melting, Refining and Casting Metals and other Substances by Electricity.* H. H. Lake, London. From E. A. Colby, Newark, U.S.A. Eng. Pat. 7876, May 20, 1890. 8d.

To obtain a perfectly homogeneous mass of a refractory metal, such as platinum, the metal is heated electrically to the point of liquefaction in a rarefied atmosphere, or in the presence of any desired gas. Alternating currents of electricity are passed round a primary coil of wire insulated with asbestos and arranged in annular form around the substance to be melted, a core of laminated iron being also employed to intensify the currents. Induced currents of great quantity are thus obtained in the substance if it be a conductor of electricity, and, if it be not, in the metallic vessel containing the substance to be treated, the heat thus produced reducing the substance to a state of fusion. Provision is made for pouring the molten material into a mould without opening the furnace.—B. T.

## XII.—FATS, OILS, AND SOAP MANUFACTURE.

#### PATENTS.

*Improvements in the Composition of Soap.* T. Anyon, Manchester. Eng. Pat. 16,518, October 19, 1889. 4d.

FINELY powdered dry neutral soap is incorporated with a powerful disinfectant such as permanganate of sodium or potassium. This powder is either used as such in sprinklers, or it is subjected to pressure to solidify it into a tablet soap.—K. M.

*An Improvement in Lubricants.* W. Brinek, Linden near Hanover, Germany. Eng. Pat. 17,163, October 30, 1889. 4d.

To impart the requisite degree of viscosity to liquid mineral oils a small quantity of caoutchouc is dissolved therein, and the solution filtered. To solid lubricants caoutchouc may also be added with advantage of economy in the course of manufacture, the lubricant not melting so easily in the bearings. Caoutchouc in an oil prevents to a great extent the liability of "gumming," to which bearings are subject with ordinary lubricants.—K. M.

### XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

*Description of the Cleator Iron Ore Company's Barytes and Umber Mines and Refining Mills.* P. L. Addison. Proc. Inst. Civil Eng. 102.

On a property known as the Caldbeck Fells, in Cumberland, umber and barytes were discovered in workable quantity about five years ago.

The vein of umber contains crystals of quartz, and lies in a granitic rock largely decomposed. The method of working is as follows:—The umber is brought down by an overhead tramway and passed through a hopper into a wash barrel consisting of a cylinder formed of parallel bars one-eighth of an inch apart, having a perforated pipe conveying water, for its axis. By this means the umber is washed through, the quartz being retained; the former then passes to an edge-runner, the casing of which is of sufficient depth to allow of the submersion of the rollers. The rate of revolution is about 14 to the minute, and the finer floating particles flow into the drag mill shown in the figure. The bed of this mill is a single block of granite and over it the four burrstone blocks shown in the plan are dragged; the

Fig. 1.

Section.

Fig. 2.

Section below A B.

DRAG MILL.

finer "floating" particles of umber pass to a second mill of the same kind, then through a brass wire sieve (to remove particles of peat and heather that have been floating throughout the process) to settling tanks, composed of brickwork lined with cement (7' x 7' x 5'). After settling

for four hours four-fifths of the water are drawn off, and the umber, now of the consistency of slurry, filter-pressed and dried. It has the following composition:—

#### *Analysis of Umber.*

	Parts per Cent.
Ferric oxide .....	47.14
Manganese dioxide .....	11.17
Cupric oxide .....	3.23
Alumina .....	7.66
Lime .....	Trace.
Magnesia .....	Trace.
Silica .....	21.70
Combined water .....	6.18
	<hr/> 100.08

In this condition it may be put on the market, serving for colouring coarse brown paper (that being the chief use to which umber is put), or it may be re-ground in a conical burrstone mill and sold to paint and oil-cloth manufacturers and the makers of the finer kinds of brown paper. The fine state of division to which it is reduced may be judged from the facts that the workman in charge of the mill is compelled to wear a respirator, and the stain is not easily removed from the hands.

The power necessary is obtained from a light overshot water wheel 30 x 2 feet.

The process for preparing barytes needs considerably greater power, a water wheel 36 x 5 being employed. Some difficulty arises from the presence of a ferruginous clay with the barytes, which necessitates a washing with acid to attain a good colour. The rough barytes is washed fairly free from clay, broken into half-inch cubes in a crusher, and ground in a flat burrstone mill, the upper stone of which weighs 35 cwt., and is driven at 120 revolutions per minute, a jet of water being allowed to play between the stones. From this the sludge flows to drag mills similar to those illustrated above in the description of the umber works. Thence it is carried to a receiving tank provided with an agitator to prevent the heavy substance sinking to the bottom and forming a caked unmanageable mass. "Bleaching" is now effected by treating the barytes, holding but little water, with sulphuric acid in the proportion of 70—80 lb. to 25—30 cwt. of the mineral. The operation is conducted in red sandstone tanks provided with agitators made of pitch-pine, experience showing that material to resist the action of the acid better than oak or other ordinary wood. After adding the acid steam is turned on, and the mixture boiled for one hour, after which cold water is run in and the contents of the tank passed into the washing vat, where repeated agitation with water removes the acid until none can be detected by litmus paper. Ultramarine blue in the proportion of 6—8 tablespoonfuls to 30 cwt. barytes is added "to give clearness to the white," excess being avoided as an objectionable "pearly tint" is produced thereby. The washed barytes is filter-pressed (on very strong cloths needed on account of its great weight), dried in a steam room, and packed into clean paraffin casks holding about 10 cwt. apiece. It has the following composition:—

#### *Analysis of Barytes.*

	Parts per Cent.
Barium sulphate .....	96.29
Silica .....	2.60
Lime and alumina .....	0.10
Ferric oxide .....	0.01
	<hr/> 99.00

Large quantities of water being needed, the mountain streams are utilised, and freed from sand and peat by the following device: The supply for grinding, bleaching, and washing is taken from the trough supplying the water wheel, the outlet being 3 in. above the floor of the trough. It flows thence to the bottom of a column of 12 in. cast-iron pipes, the upper parts of which are only 9 in. in diameter. Between the two portions is a diaphragm of brass gauze (1,600 meshes per square inch), and above this the purified

supply is taken. A sludge cock at the bottom allows of an occasional blow-off, cleaning at the same time the wire gauze. The water being always drawn from the top of what is in effect a very deep settling tank, is free from sand and other impurities.—B. B.

*The Analysis of Celluloid.* H. Zauschirm. Chem. Zeit. 14, 905.

See under XXIII., page 979.

## PATENTS.

*Improvements in Elastic Sheets or Tubing.* L. W. Leeds and P. S. Justice, London. Eng. Pat. 13,053, August 19, 1889. 4d

This invention consists in the application of an elastic coating to the tube or sheet while the latter is in an expanded condition. The rubber or other elastic tubes are expanded by air under considerable pressure, and soluble rubber, elastic varnish, or other suitable material is then applied to the internal or external surface, or the coating material may be forced into the tube under sufficient pressure to expand it to the desired degree, the pressure being subsequently removed and the excess of material run from the tube, which may then be internally polished by forcing through it one or more shuttles or marbles, and finally dried by heated air or other means.—E. G. C.

*Improvements in Translucent Plastic Compositions.* F. Eckstein, Vienna, Austria. Eng. Pat. 14,569, September 16, 1889. 4d.

The inventor describes his composition, "hyaline," as a "horny, translucent, plastic composition of great tensile strength and considerable elasticity, which may be used as a cheap and inodorous substitute for celluloid, and can be worked, dyed, pressed, denitrated, and rendered incombustible or fireproof." "Hyaline" is a mixture of about equal parts of gum-cotton and colophony, or shellac, copal, dammar, turpentine, or of any mixture of these resins.

—E. G. C.

*Improvements in Paints or Compositions for Covering Surfaces.* R. Barton, Hull. Eng. Pat. 14,797, September 19, 1889. 4d.

KIESELGUHR (12 parts) is mixed with linseed or colza oil (3 parts) and carbonate or oxide of lead, baryta, or the like (5 parts), any suitable colouring matter, such as lamp black, ochre, ultramarine, &c. being added.—E. G. C.

*An Improved Polish for Cleansing and Reviving Furniture and Analogous Articles.* J. Simpkins, Winchester. Eng. Pat. 15,180, September 26, 1889. 4d.

The composition is as follows:—"Beer, waste beer, cold tea, or vinegar, 48 parts;" methylated spirit or finish, 32 parts; dragon's blood, 1 part; gum benzoin, 3 parts; linseed oil, 16 parts.—E. G. C.

*A New Pigment or Paint Base and Processes of producing the same.* W. L. Wise, London. From J. P. Perkins, New York, U.S.A. Eng. Pat. 15,805, October 8, 1889. 6d.

A VARIETY of bright red pigments consisting of a mixture of ferric oxide and silica are produced from silicious ferruginous slag. The pulverised slag is either treated with sulphuric acid, and the resulting mass gradually heated to a light red heat (never above 1800°) till all sulphuric acid is driven off, or it is heated in presence of air and then treated with sulphuric acid with subsequent heating. The latter method requires more fuel but less sulphuric acid than the former, the product being substantially the same. The resulting

pigment can easily be ground to an impalpable powder, and consists of ferric oxide and silica in the proportion of about 25 parts of silica to 75 parts of the oxide. The shade of colour may be varied by varying the amount of sulphuric acid used, the more acid used, the brighter the red. Owing to the extremely fine condition and opacity of the silica set free by the action of the acid on the silicates in the slag, these pigments are brighter and more pronounced in colour than those pigments produced by mixing ordinary Venetian reds with ground silica.—K. M.

*Improvements in and relating to the Manufacture of Vulcanised Plastic Compounds.* A. J. Boulton, London. From W. Kiel, Butler, U.S.A. Eng. Pat. 9822, June 24, 1890. 6d.

This invention relates to the manufacture of vulcanised rubber, having several advantages over the material as ordinarily prepared. The product may be made either hard and rigid, in which case it takes a higher polish, is not so brittle, and can be more readily turned in a lathe; or it may be made so flexible that a rod or tube may be twisted to any shape.

The ingredients for the manufacture are crude rubber, sulphur, and mineral oil, in the proportions of about equal parts of rubber and sulphur, the oil varying from  $\frac{1}{16}$  to  $\frac{1}{2}$  of the sulphur, according to the degree of hardness required. The compound is vulcanised at a steam pressure of not less than 60 lb., the operation lasting about three hours; or by increasing the pressure to 100 lb. the vulcanisation may be completed in one hour (see this Journal, 1889, 204, and 1890, 398).—F. H. L.

*Improvements in making White Pigments of Lead.* J. Gordon, Bridge of Allan. Eng. Pat. 9897, June 26, 1890. 6d.

GALENA, in the state of fine powder, is injected, by means of a current of compressed air, into the upper part of a eupola furnace fed with coke. The oxidised product, consisting of sulphite, sulphate and oxide of lead in varying proportions, is drawn, by means of an exhausting apparatus, into a wet fume condenser containing water acidulated with hydrochloric acid to remove impurities.

Drawings of a suitable furnace are given.—F. H. L.

*A New or Improved Process for producing Minium.* M. Alsborg, New York, U.S.A. Eng. Pat. 10,130, July 1, 1890. 4d.

A MIXTURE of litharge or white lead and lead nitrate, prepared either by mixing together 100 parts of lead oxide, 18.6 parts of lead nitrate, and 15 parts of water, or by adding 7.1 parts of dilute nitric acid to 100 parts of litharge, is exposed to a temperature of from 700° to 900° F., care being taken not to reach a red heat.—F. H. L.

## XIV.—TANNING, LEATHER, GLUE, AND SIZE.

*Wattles and Wattle Barks, being Hints on the Conservation and Cultivation of Wattles, together with Particulars of their Value.* J. H. Maiden, Department of Public Instruction, Sydney, N.S.W. 1890.

AT present only the following wattles are recommended to be planted:—

The South Australia broad-leaved wattle, *Acacia pycnantha*, the Sydney black wattle, *Acacia decurrens*, and the Tasmanian and Victorian black wattle, *Acacia mollissima*. Throughout Australia the species of wattle richest in tannin

are becoming seriously diminished, and tanners will have to fall back on second-grade barks, unless the cultivation of good barks is actively entered on. For bark which in 1872 cost from 2*l.* 10*s.* to 3*l.* 15*s.* per ton, 8*l.* or 9*l.* was paid in 1887. The best Sydney bark has fetched 10*l.* this season and this appears to be the top average price.

**CULTIVATION OF WATTLES.**—Wattles will grow on the poorest soils where not even grass grows. Sandy soil is best, lying upon a clay subsoil. A moderate amount of moisture, say from 18 to 20 inches per annum, is best; an unlimited supply of moisture is prejudicial.

The outer covering of the seed is of great hardness and the seed requires to be heated, either by moist or dry heat, to ensure early germination.

Wattle trees are sometimes recommended to be pruned, but this is to be deprecated in warm northern exposures as too much sun would be admitted to the stem of the tree.

Under the section *Profits to be Derived from Wattle Cultivation*, detailed estimates are given in which it is shown that the "profit balance" exclusive of improvements or supplementary sowings, on a wattle plantation of 100 acres during eight years, amounted to a total of 2,637*l.* Other estimates are given showing similar results.

**WATTLE BARKS IN GENERAL.**—(a.) *Time of Year for Stripping.*—Wattles should only be stripped for three or four months in the year, as when stripped out of season there is usually a depreciation of the tannin. September, October, November, and December are recommended, but no fixed time applicable to all parts of the country and to varying seasons, can be given. Bark should be purchased in the stick or bundle, and tanners are warned against receiving it in a damp state as it engenders mould "of a most virulent description and is liable to spontaneous combustion."

(b.) *Age and Size of Trees.*—Bark may be stripped at the end of five years, and no stems under five inches in diameter should be cut.

(c.) *Export, Packing, &c.*—Barks are sent into commerce in one or more of four forms:—(1.) In the bundle. (2.) Chopped, i.e., into pieces a few inches in length. (3.) Ground, forming a substance something like "tow." (4.) Powdered. Extract has been made from the wattle "trash" which yields 12 to 16 per cent. of tannage. This extract, however, contains a large amount of gum and mucilage, and some cheap process of getting rid of this mucilage is a desideratum.

**THE VARIOUS KINDS OF WATTLE BARKS.**—This section contains a description (illustrated with seven full page drawings of wattles) of the various wattle barks, with observations and analyses partly given before in a paper by the author which is published in *Proc. R.S., N.S.W.*, 1887, 30; this Journal, 1888, 38 and 392. The following is synopsis of wattle bark analysis performed by the author. The percentage of tannin in each case was determined on the bark dried at 100° C. by the improved Löwenthal method. The local name, species name, percentage of tannin, and where grown are given in the order named.

**Valuable Wattle Barks.**—Black wattle, *Binervata*, 19·3 to 30·4, N.S.W.; broom wattle, *Calamifolia*, 36·06, S.A.; black wattle, *Decurrens*, 24·13 to 36·3, N.S.W.; Mountain hickory, *Elata*, 20·1 to 31·1, N.S.W.; Tasmanian, black or green wattle, *Mollissima*, 24·63 to 35·3, N.S.W.; Hickory, *Penninervis*, 14·49 to 31·0, Q.; broad-leaved wattle, *Pycnantha*, 16·24 to 46·47, S.A.; weeping wattle, *Vestita*, 27·96 to 33·2, N.S.W.

**Wattle Barks of Secondary Value.**—, *Amara* 23·5, N.S.W.; silver wattle, *Dealbata*, 17·1 to 25·9, N.S.W.; golden wattle, *Longifolia*, 5·0 to 18·93, N.S.W.; Sally, *Longifolia* var. *Floribunda*, 2·54 to 6·09, N.S.W.; Blackwood, *Melanoxylon*, 11·12, N.S.W.; A black wattle, *Nerifolia*; —, Q.; a silver wattle, *Podalyriaefolia*, —, Q.; grey wattle, *Promincens*, 14·42 to 18·03, N.S.W.; — *Pruinos*, 24·25, N.S.W.; Cooba, *Salicina*, 13·21 to 15·1, N.S.W.

**WORTHLESS WATTLE BARKS.**—Mulga, *Aucura*, 2·32 to 8·62, N.S.W.; Wait-a-while, *colletoides*, 4·4, N.S.W.;

a black wattle, *Cunninghamii*, —, Q.; —, *Flavescens*, —, Q.; Myall or boree, *Glaucescens*, 8·10, N.S.W.; Curly yarran, *Homalophylla*, 9·06, N.S.W.; —, *Impleta*, 7·82, N.S.W.; —, *Leptocarpa*, —, Q.; Miljee, *Oswaldi*, 9·72, N.S.W.; Bastard gidgee or myall, *Pendula*, 3·25, N.S.W.; Yarran, *Pendula*, var. *glabrata*, 7·15, N.S.W.; —, *Polystachya*, —, Q.; —, *Pravissima*, 10·66, N.S.W.; Nealie or needle-bush, *Rigens*, 6·26, N.S.W.; —, *Sentis*, 6·32 to 10·26, N.S.W.; —, *Siculiformis*, 7·87, N.S.W.; —, *Stenophylla*, 9·49, N.S.W.; River wattle, *Subporosa*, 6·6, N.S.W.; Dead finish, *Tetragonophylla*, 5·59; —, *Verniciflua*, 3·16, N.S.W.

A small chapter is also devoted to a discussion of the similarities and dissimilarities of *Acacia decurrens*, *Mollissima* and *Dealbata*. A very complete index is given at the end of the pamphlet.—B. H.

#### *On the Action of Phenylhydrazine on Tannin Extracts.* C. Böttinger. *Annalen*, 259, 125—132.

PURE tannins yield with phenylhydrazine different kinds of derivatives which do not crystallise and do not allow of satisfactory separation. The amorphous form of the compounds is evidently a consequence of their high molecular weight. The tannin materials experimented with were extracts of sumac, divi-divi, oakwood, oak-bark, and pine-bark. The diluted extract was heated with phenylhydrazine for six to eight hours on a water-bath, whereby a precipitate was obtained which was filtered off, washed with water and air-dried. During the operation a considerable evolution of carbonic acid and apparently nitrogen took place, at the same time a part of the phenylhydrazine was decomposed into ammonia and azobenzene. 100 cc. phenylhydrazine yielded 248 grms. of air-dried precipitate from oak-bark extract, and 175 grms. from pine-bark extract. The precipitate contained phenylhydrazine derivatives of tannic and gallic acids and osazones of dextrose and levulose, together with amorphous substances similar to caramel.—G. H. B.

#### *On Gallic, Tannic, and Gallotannic Acids.* C. Böttinger. *Annalen*, 259, 132—136.

THE author has endeavoured to effect the union of hydrocyanic acid with the acids of the tannin group, and for this purpose the acetyl and benzoyl derivatives of the tannins were boiled for several hours with an aqueous solution of potassium cyanide in excess. No cyanogen compound was obtained, but ammonium formate was produced and the tannin was changed to gallic acid. Well dried tannin heated with anhydrous hydrocyanic acid in a sealed tube in boiling water yielded only an amide of gallic acid. Victor Meyer's employment of hydroxylamine chloride as a reagent for ketones and aldehydes is of such utility that the same investigator entertained the idea that the reaction might play a part in the actual growth of plants, but he was unable to trace it in nature. The author thinks that he has found a reason for this in the fact that none of the tannin acids could be made to react with hydroxylamine.—G. H. B.

## XV.—AGRICULTURE, MANURES, Etc.

*Wattles and Wattle Barks, being Hints on the Conservation and Cultivation of Wattles, together with Particulars of their Value.* J. H. Maiden, Department of Public Instruction, Sydney, N.S.W. 1890.

See under XIV., page 954.

*Loss of Nitrogen in the Decay of Nitrogenous Organic Substances.* H. v. Krause. *Jour. f. Landw.* 38, 1.

THE experiments were made in glass flasks on one litre of cow's urine, and may be divided into two groups. (1.) Experiments on the influence of various substances, with free access of air and with limited access of air, upon

the decay of nitrogenous organic substances, as well as their influence on loss of nitrogen generally. (2.) Experiments on the loss of free nitrogen in the presence of different preservatives.

The substances added were superphosphate, superphosphate and gypsum, gypsum, kainit, potassium chloride, salt, Thomas-slag (85 per cent. fine), peat and distilled water.

Superphosphate is the best preservative of nitrogen, surpassing in this respect the much recommended superphosphate and gypsum, smaller quantities of the pure superphosphate being required; the richest superphosphates are the best.

Gypsum has a tendency to promote rather than hinder fermentation; it can retain an amount of ammonia equivalent to its sulphuric acid. Rapid fermentation, however, means a greater loss of free nitrogen, so that gypsum is not a good preservative.

Kainit was found to be good for a short time, but after fermentation had set in, the loss, especially of free nitrogen, was very great; the practical conclusion therefore is that kainit should be used only when the dung is to be a short time in the heap.

Peat promotes fermentation, and loss of nitrogen, especially free nitrogen, is considerable. At first the peat prevents loss because its humic acid combines with the ammonia; also because it retains water. Practically peat may be used when the dung heap requires solidifying.

Thomas-slag is useless as a preservative; it promotes fermentation and cannot absorb ammonia.—A. G. B.

#### *The Distribution of Boracic Acid in Plants.* J. S. Callison. Jour. Anal. Chem. 1890, 191.

CERTAIN plants seem to possess a peculiar assimilating power for boracic acid, others are found perfectly free from it, although growing with the former plants in the same soil. Of the 92 plants examined by the author, eight contained no boracic acid. It must be assumed that the plants obtain the acid from the soil although in no case was it found either in the soil or in the spring water. Analyses of certain manures such as bone manure and Pern guano, as well as of potassium chloride and kainit from Stassfurt, indicated the presence of considerable quantities of boracic acid. (See also this Journal, 1889, 569.)—A. R.

#### PATENT.

##### *Improvements in the Manufacture of Manures and Fertilisers.* M. C. Gunster, Birmingham. Eng. Pat. 575, January 13, 1890. 4d.

THE object of this invention is to produce, by chemical means and without the employment of machinery, a rich fertiliser possessing a high percentage of ammonia and phosphates from blood or blood and fish combined, or other organic matter. The blood is collected in suitable vessels, then passed through a screen into a tank. 35—40 lb. of oil of vitriol to the ton of blood are then added, and the mixture is stirred for 10—15 minutes. The mixture is allowed to stand 10—12 hours, and then transferred to a press and the liquid drained off. The solid substance is broken up and dried in the sun or in a kiln at a temperature not exceeding 100° F. This manure contains about 14 per cent. nitrogen. The press liquor is said to form a good manure if mixed with some dry substance such as bone or wool dust.

The fish are treated in a similar manner to the above. They are first finely chopped, however, before being put into the tank. 35—40 lb. of acid to the ton are used, the mixture stirred for 15 minutes, and allowed to stand 6—8 hours. The liquid is then drained off and treated similarly to the blood liquid. The solid substance is sun- or kiln-dried at a temperature not exceeding 80° F. This manure contains a high though variable percentage of phosphate and ammonia.—F. W. T. K.

## XVI.—SUGAR, STARCH, GUM, Etc.

### *On the Estimation of Raffinose and Invert Sugar in the Products of the German Beet Sugar Manufacturers.* Chem. Zeit. 14, 854—855.

See under XXIII., page 978.

### *"Fucusaldehyde," a Mixture of Furfuraldehyde and Methylfurfuraldehyde.* K. Bieler and B. Tollens. Annalen, 258, 110—128.

THE compound termed "Fucusol," obtained by Stenhouse by distilling seaweed with sulphuric acid, is generally regarded as an isomeride of furfuraldehyde, but the very slight differences between these substances made it seem probable to the authors that it is only a mixture of that substance with some difficultly separable homologue. A revision of Stenhouse's work was undertaken to decide this point, and to determine the identity of the oil resembling furfuraldehyde, obtained by one of the authors and Stone and Wheeler (Ann. 254, 304) from arabinose. During the progress of the experiments Hill (Ber. 22, 607; this Journal, 1889, 973) isolated from the furfuraldehyde obtained by the distillation of wood, a higher homologue, which he regarded as "Methylfurfuraldehyde." Maquenne (Compt. Rend. 109, 571 and 603; this Journal, 1889, 974) examined fucusaldehyde, and obtained results agreeing with those of the authors, and Oliveri and Peratoner (Gazz. 19, 633) separated fucusaldehyde into furfuraldehyde and a compound of a higher boiling point. The authors draw the following conclusion from their experiments: (1.) Fucusaldehyde from seaweed is merely a mixture of furfuraldehyde and methylfurfuraldehyde. (2.) The furfuraldehyde from seaweed and its derivatives are identical with the compounds obtained from bran. (3.) Methylfurfuraldehyde boils at 182°—184°, gives an orange-red colouration with aniline acetate, yields a hydramide melting at 87°, and a methylpyromucic acid melting at 108°; it also exhibits a fine green colouration when treated with sulphuric acid and isatin. (4.) A sugar may be separated from seaweed which yields furfuraldehyde or methylfurfuraldehyde, and a hydrazone which resembles rhamnose hydrazone, but has a higher melting point. It has not yet been crystallised.—S. B. A. A.

### *Carbohydrates of the Sweet Potato (Batatas Edulis).* W. E. Stone. Ber. 23, 1406—1408.

SWEET potatoes of the varieties "American Red" and "Southern Queen" are found to contain  $\frac{1}{4}$  to 2 per cent. of cane sugar, a large proportion of starch, but no reducing sugar. Baking develops dextroses and glucoses from these constituents.—D. A. L.

### *A New Crystalline Carbohydrate.* A. v. Planta and E. Schulze. Ber. 23, 1692—1699.

THE extract obtained from the tubers of *Stachys tuberosa* by pressing and washing with water is precipitated firstly with lead acetate, then with mercuric nitrate, treated with hydrogen sulphide, filtered, neutralised with ammonia, evaporated to a syrup and poured into alcohol. The syrupy precipitate is mixed with phosphotungstic acid, filtered, treated first with barium hydroxide to remove the excess of phosphotungstic acid, then with carbonic anhydride to remove the barium, and the final filtrate is evaporated to a small volume and poured into absolute alcohol. The precipitate obtained in this manner is dissolved in water and re-precipitated with alcohol two or three times, and is finally crystallised from 91 per cent. (by volume) alcohol. The crystals assume two forms, of one of which, tablets, the measurements are given:—

$$\alpha = 88^\circ 41\frac{1}{2}', \beta = 92^\circ 32\frac{1}{2}', \gamma = 153^\circ 43\frac{1}{2}'. \quad a:b:c = 0.7848:1:2; \quad c = 0 \text{ P } (001), \quad b = \alpha \text{ P } \underline{x} \quad (010), \quad p = \alpha \text{ P}_1(110), \quad p' = \alpha'_1 \text{ P } (110), \quad p'_2 = \alpha'_1 \text{ P } \frac{8}{9} \quad (890).$$

They are colourless, hard and glistening, lose 9.67 per cent. of water of crystallisation at  $103^{\circ}$ — $104^{\circ}$ , but above that temperature undergo decomposition. Various analyses point to the composition  $C_{36}H_{62}O_{31} + 7 H_2O$ ; the water of crystallisation is very slowly removed by exposure over strong sulphuric acid, being incomplete after many weeks. The aqueous solution is dextro rotatory, a 9.0 per cent. solution in a Soleil-Ventzke apparatus showing  $[\alpha]_D = +148.1^{\circ}$ , and is without action on Fehling's solution. With nitric acid it yields mucic acid, and gives a red colouration and precipitate with resorcinol and hydrochloric acid, but not with phloroglucinol. Lead acetate produces a precipitate in the presence of alcohol or ammonia, but not in the ordinary aqueous solutions. Barium and strontium hydroxides do not precipitate this carbohydrate. It is readily inverted, half the product being galactose; the specific rotation after inversion =  $[\alpha]_D = +75^{\circ}$ . This carbohydrate has a very slightly sweet taste, of known compounds of this description it most resembles lactosin, but is not considered identical with it, and has been named by the discoverers stachyose.—D. A. L.

*Contributions to a Knowledge of the Carbohydrates.* A. Wold. Ber. 23, 2084—2110.

AFTER giving a short account of the investigations previously published concerning the action of dilute acids on different carbohydrates, and especially on cane sugar, the author proceeds to give an account of his own experiments.

In a research which he has made working with Kolbrepp, on the inversion of cane sugar by hydrofluoric acid, it was found that with concentrated solutions the less the quantity of acid used, the greater was the maximum observed levo-rotation. Further experiments have shown that this held good with other mineral acids. By heating on the water-bath 80 parts of pure cane sugar with 20 parts of water and 0.004 parts hydrochloric acid for one hour, a pure colourless invert sugar was obtained, which on standing crystallised.

**I. Action of Hydrochloric Acid on Concentrated Solution of Cane Sugar.**—The following experiments were made, the solutions being digested for 30 minutes in a closed flask in boiling water:—

40 per cent. solution with 0.06 per cent. HCl (on the sugar) gave  $-15.4^{\circ}$  and — mgrms. Cu.

60 per cent. solution with 0.025 per cent. HCl (on the sugar) gave  $-14.1^{\circ}$  and 306 mgrms. Cu.

76.6 per cent. solution with 0.01 per cent. HCl (on the sugar) gave  $-13.15^{\circ}$  and 302 mgrms. Cu.

80 per cent. solution with 0.01 per cent. HCl (on the sugar) gave  $-12.3^{\circ}$  and 296 mgrms. Cu.

88 per cent. solution with 0.01 per cent. HCl (on the sugar) gave  $-16^{\circ}$  and 260 mgrms. Cu.

92.6 per cent. solution with 0.01 per cent. HCl (on the sugar) gave  $+0.5^{\circ}$  and — mgrms. Cu.

Calculated for complete conversion  $-16.1^{\circ}$  and 313 mgrms. of Cu.

Further heating of one of these solutions containing 13.024 grms. sugar and 3.3 cc. dilute hydrochloric acid (0.01 per cent. HCl on the sugar) diminished the observed angle and cupric reducing power. In the most concentrated solution the boiling point of water was not hot enough to properly fuse the mixture, and so inversions with this concentration were made at  $105^{\circ}$ — $110^{\circ}$ .

0.01 per cent. HCl (on the sugar) gave  $-12.3^{\circ}$  and 296 mgrms. Cu. Solution colourless.

0.02 per cent. HCl (on the sugar) gave  $-10.0^{\circ}$  and 286 mgrms. Cu. Solution light yellow.

0.03 per cent. HCl (on the sugar) gave  $-6.5^{\circ}$ . Solution yellow.

0.05 per cent. HCl (on the sugar) gave  $-4.6^{\circ}$ . Solution deep yellow.

These experiments may be explained by supposing that either the whole of the cane sugar is not converted or that in these concentrated solutions the invert sugar is not in the same state as it is in weak solutions. Experiments with much stronger acid show that it is not due to the destruction of the levulose. To enlighten this point the second series of experiments were made.

**II. Action of Hydrochloric Acid on Concentrated Invert Sugar Solution.**—The invert sugar was prepared by mixing solutions of pure levulose and dextrose in equal proportions. It had all the properties of invert sugar. The following comparative experiments were made:—

I. 3.425 grms. dextrose and levulose were heated in a 50 cc. flask with 1 cc. dilute hydrochloric acid (0.04 per cent. HCl) and 0.35 cc. dilute hydrochloric acid (0.08 per cent. HCl) for 17 minutes in boiling water. The concentration of the solution corresponded to a 80 per cent. solution of cane sugar completely inverted and containing 0.01 per cent. HCl on the sugar before inversion. The polarisation was  $-12.7^{\circ}$  instead of  $15.8^{\circ}$ , the angle for pure invert sugar.

II. 6.512 grms. of cane sugar with 1.7 cc. dilute hydrochloric acid (0.04 per cent. HCl) was treated in exactly the same way. The polarisation was  $-12.3^{\circ}$ .

III. Experiment I., with 30 minutes heating, gave  $-12.05^{\circ}$  and 295 mgrms. of Cu.

IV. Experiment II., treated in the same way, gave  $-12.25^{\circ}$  and 296 mgrms. of Cu.

V. Experiment I., with 60 minutes heating, gave  $-10.6^{\circ}$  and 287 mgrms. of Cu.

VI. Experiment II., in the same way, gave  $-10.5^{\circ}$  and 288 mgrms. of Cu.

If the acid be omitted in the above experiments, the heating will not alter the properties of the invert sugar. It is thus evident that in concentrated solutions, under the above conditions, a condensation of invert sugar is effected.

**III. Action of Hydrochloric Acid on Concentrated Levulose Solution.**—6.85 grms. of levulose treated in the same way gave  $-63.5^{\circ}$  and 264 mgrms. of Cu. The numbers for pure levulose are  $-73.1^{\circ}$  and 300 mgrms. of Cu.

Other experiments gave similar results. It is, therefore, evident that the condensation observed is not a reproduction of cane sugar, but merely a condensation of the levulose.

**IV. Levulosin.**—This is the product obtained by the above condensation. It was prepared by heating levulose in concentrated solution with 0.01 per cent. of HCl in boiling water for one hour.

The polarisation fell from  $-36.15^{\circ}$  to  $-18.8^{\circ}$ , and the reduction from 153 mgrms. to 81 mgrms. of Cu. The product was dissolved in hot absolute alcohol, and on cooling a dextrinous precipitate separated. It was purified by washing and reprecipitation from its solution in hot alcohol, and dried over sulphuric acid. It has an optical activity about one-half, and a cupric reducing power about one-third, of that of levulose. On digestion with dilute acids these numbers increase, and approach those of levulose, so that in all probability levulose is produced.

**V. Action of Hydrochloric Acid on Dextrose.**—Concentrated dextrose solutions, 80 per cent., were acted on at  $105^{\circ}$  with 0.05—1.0 per cent. HCl for half an hour, one hour, and two hours. The optical activity was found to increase and the reducing power to diminish, these changes being proportional to the strength of acid and duration of heating.

**VI. Reversion and Inversion.**—The author considers that Tollen's oxy-formulae for dextrose and levulose best explain their condensation as above described under the influence of dilute acids.

**VII. On the Saccharification of Starch.**—It has been noted by various observers that in the saccharification of starch by dilute acid, the theoretical numbers for dextrose are never obtained. The author has acted on dextrose under the same conditions as the conversion of starch usually takes place, and finds that the optical activity increases and the cupric reducing power diminishes with the duration of the reaction. He gives a formula for this.

**VIII. The Preparation of Dextrin by the Action of Small Quantities of Nitric Acid and Water on Starch.**—The author considers that part of the dextrin produced is due to reversion of the dextrose. In an experiment he found that a concentrated solution of dextrose heated with a small

quantity of nitric acid for half an hour, showed an increase in the optical activity and diminution in the cupric reducing power.

**IX. Saccharification of Inulin.**—Owing to the rapidity in which levulose is acted upon by dilute acids, it is important, when saccharifying inulin, to work under the most favourable conditions. The author finds that with 80 per cent. solutions and 0.11 per cent. of HCl on the inulin, the maximum of rotation, equivalent to 86 per cent. of the theoretical yield of sugar, is reached in 25–30 minutes at 100°. Honig and Schubert, with a 17 per cent. solution, obtained 91 per cent., and with a 4.62 per cent. solution 93.8 per cent. of the theoretical yield.

**X. Preparation of Levulose.**—In the preparation of levulose, if much acid is used, or if the syrup has to be exposed to high temperature (evaporation) for any length of time, much colour is developed, and it is very difficult to get the levulose to crystallise. The following method is stated to yield a pure product: 50 cc. of water, 200 grms. of inulin, and 0.02 gm. HCl (more hydrochloric acid if the inulin contains ash) are placed in a half-litre flask, and digested for half an hour in the water-bath; sufficient chalk is then added to neutralise the acid. The concentrated solution is dissolved in 1 litre absolute alcohol, decolourised by a small quantity of blood charcoal, and, after standing 12 hours, poured off the residue. If a few crystals of pure levulose are introduced into the solution, a crop of pure crystalline levulose will separate. It is, however, better to evaporate the alcoholic solution in vacuo to a thick syrup, which, when placed over sulphuric acid, soon solidifies to a crystalline mass of levulose. This is dissolved in 3–4 times its weight of absolute alcohol, and if a crystal of levulose be added to the clear solution, a crop of pure levulose soon separates.—A. L. S.

#### *Synthetical Researches in the Sugar Group.* E. Fischer. Ber. 23, 2114.

A LECTURE delivered before the German Chemical Society, giving a complete account of our present knowledge concerning the constitution of the sugars and their synthesis. All the work has been published and is contained in papers by Fischer, Kiliani, Scheibler, Maquenne, Löwe, Tollens, and others, the greater portion of which has been abstracted in the last few volumes of this Journal and that of the Chemical Society.—A. L. S.

#### *On Sugars richer in Carbon from d-Mannose.* Fischer and Passmore. Ber. 23, 2226–2239.

THE authors have proceeded, according to the method they have already indicated (this Journal, 1890, 638), to build up from mannose sugars containing 7, 8 and 9 atoms of carbon and which they have called mannoheptose, mannoctose, and mannnonose, and the corresponding acids heptonic, octonic, and nononic acids, and the corresponding alcohols heptitol, nonitol, from their synthesis it follows that all these bodies contain a normal carbon chain and the sugars are aldehydes.

**d-Mannoheptonic acid** (mannose-carboxylic acid), described in their first communication (this Journal, 1890, 638), they have obtained in quantity from vegetable ivory shavings, by hydrolysing with sulphuric acid, acting on the solution with hydrocyanic acid, and decomposing the amide with baryta, when the barium salt of *d*-mannoheptonic acid is obtained, which is purified by crystallisation; the barium removed by sulphuric acid and the pure acid or its lactone crystallised. The acid melts at 175° C., and by heating is converted into its lactone which melts at 148°–150° C.; its aqueous solution is levo-rotatory  $[\alpha]_D = -74.2$  at 20°.

**d-Mannoheptose** is prepared by reducing the *d*-mannoheptonic lactone with sodium amalgam, the solution being kept in a freezing mixture, and just acid with sulphuric acid. When the reduction is complete the solution is made alkaline with soda, filtered, neutralised with sulphuric acid,

evaporated to a syrup on the water-bath, and added to 10 times its bulk of boiling absolute alcohol. The alcoholic mother-liquor is evaporated to a syrup, and in one or two days the sugar crystallises out; this cannot be easily purified from heptitol, the corresponding alcohol, except by preparing the hydrazone and reconvertng this into the sugar. It crystallises in fine needles having a composition corresponding to the formula  $C_7H_{14}O_7$ , melting point 134°–135°; it has a sweet taste, is easily soluble in water, difficultly in absolute alcohol. Its aqueous solutions are dextro-rotatory and show bi-rotation, the constant value is  $[\alpha]_D = 68.64$ . It is not fermentable with yeast. It yields a hydrazone,  $C_7H_{14}O_6 \cdot N_2H \cdot C_6H_5$ , which is very difficultly soluble in water, melting point 197°–200°, and an osazone,  $C_7H_{12}O_6 \cdot (N_2HC_6H_5)_2$ , melting point 200°.

**Mannoheptitol** is produced by reducing mannoheptose by sodium amalgam in acid solution, the product is purified by crystallisation from water and alcohol, it melts at 188° C. It forms a pentacetyl derivative, melting point 119°. A careful comparison of it with the naturally produced body *perseitol* (Maquenne, Ann. Chim. Phys. [6], 19, 1) showed that they were identical. The authors have converted the natural perseitol by oxidation into the above-described mannoheptose.

**d-Mannoctonic acid** is prepared by the action of hydrocyanic acid on mannoheptose just as mannoheptonic acid is obtained from mannose. Its lactone tastes sweet, melting point 167°–170° C. with decomposition, its solution is levo-rotatory  $[\alpha]_D = -43.58$  at 20° C.; it forms a hydrazone, melting point 243°,  $C_8H_{16}O_8 \cdot N_2H \cdot C_6H_5$ .

**d-Mannoctose**,  $C_8H_{16}O_8$ , is obtained by reduction of the above acid just as *d*-mannoheptose is obtained from its corresponding acid. The sugar is very easily soluble in water and difficultly in absolute alcohol. It tastes sweet and does not ferment with beer yeast. Its aqueous solutions are levo-rotatory  $[\alpha]_D = -3.3$  at 20° C. It forms a difficultly soluble hydrazone,  $C_8H_{16}O_7 \cdot N_2H \cdot C_6H_5$ , melting point 212° with decomposition, and an osazone,  $C_8H_{14}O_6 \cdot (N_2HC_6H_5)_2$ , melting point 223° with decomposition.

**d-Mannoctitol** is obtained by the reduction of the above sugar; it is only slightly soluble in water. It has a composition expressed by the formula  $C_8H_{18}O_8$ , melting point 258° C.

**d-Mannnononic acid** is obtained from *d*-mannoctose in the same way as the previously described acids were obtained from the corresponding sugars. Its lactone,  $C_9H_{18}O_9$ , melting point 175°–177° C. is easily soluble in water and levo-rotatory  $[\alpha]_D = -41.0$ . It forms a hydrazone difficultly soluble in water, melting point 254° C. with decomposition.

**d-Mannnonose**,  $C_9H_{18}O_9$ , is obtained by reducing the last described lactone. It melts at about 130° and is dextro-rotatory, having  $[\alpha]_D$  about 50°. It forms a hydrazone,  $C_9H_{18}O_8 \cdot N_2H \cdot C_6H_5$ , difficultly soluble in cold water, melting point 223° with decomposition, and an osazone, melting point 217°. It ferments with beer yeast as easily as dextrose, which it in many ways resembles.—A. L. S.

## XVII.—BREWING, WINES, SPIRITS, Etc.

*On the Purification of Raw Spirit and Brandy by the Process of Traube and Bodländer; a Report on Experiments performed to test the Value of the Process.* Zeits. f. Spiritusindustrie, 13, 75, 81, 91, 97.

For an account of the process, see this Journal, 1888, 762; 1889, 559 and 995.

The experiments consisted in the determination of the alcohol, fusel oil, and potassium carbonate in the various layers formed in the apparatus, and also in the determination of the alcohol and fusel oil in the raw spirit and distillates. The alcohol was determined by the specific gravity,

the fusel oil by the chloroform extraction method, and the potassium carbonate by titration. The distillate was usually divided into 11 fractions of about 10 litres each. One litre of each was put on one side for analysis, and the remainder of the first nine fractions mixed to form an average sample such as would be obtained commercially. As the distillation was always carried on until the whole of the alcohol had passed over, the last two fractions, being very poor in alcohol, were not added to the average sample.

A distillation carried on in this way gave the following result:—

	Per Cent. Vol. of Alcohol.	Per Cent. Vol. of Fusel Oil.
Raw spirit.....	80.42	0.303
Average sample.....	75.95	0.171
1st 10-litre portion.....	..	0.322
4th 10-litre portion.....	..	0.240
7th 10-litre portion .....	..	0.085
8th, 9th, 10th, and 11th 10-litre portion	..	0

37 per cent. of the fusel oil has thus been removed.

As in the Traube process, pure spirit and potassium carbonate are only used to form the layers in the last stages, but in the first stages raw spirit and spirit from the next vessel in the series is used, so a certain quantity of fusel oil must be introduced at each operation. The difference between the amount contained in the alcohol added and that skimmed off previously shows the net gain or loss of fusel oil. One experiment gave the following:—

Formation of Layer.	Alcohol.	Fusel Oil.
	Litres.	cc.
1st	+ 1.130	+ 7.6
2nd	+ 0.822	+ 8.2
3rd	+ 1.338	+ 7.9
4th	- 0.482	- 10.8
5th	+ 0.029	- 11.4
6th	+ 0.030	- 10.3
7th	- 0.019	- 12.0
8th	- 1.355	- 43.5
9th	- 0.782	- 24.0
Total .....	+ 0.692	- 88.3

That is, although in the first three operations there was a gain of fusel oil, on the whole the total loss was 88.3 cc.; in the raw spirit there was 0.303 per cent. vol. of fusel oil, i.e., in the quantity used 257.5 cc. fusel oil, so that 34.3 per cent. vol. fusel oil had been removed. Other experiments gave similar results.

Experiments were then made with the improved process, whereby a sharper separation of the layers was obtained, and the distillation was made with and without a column. First runnings and after runnings were also separated, and the average sample taken only of the middle fractions.

*Experiment without a Column.*—Thirteen layer formations. A first running and 10 fractions obtained by distillation. The average sample was taken of the first six and half of the seventh fractions; the other half of the seventh and eighth was used in forming a layer in a succeeding operation, the ninth and the first runnings was put on one side with other impure portions, and the 10th was thrown away.

The raw spirit contained....	0.114 per cent. vol. of fusel oil.
The first runnings contained	0.157 " "
The average sample (as above) contained .....	0.033 " "

and contained 20 per cent. of the fusel oil and 76 per cent. of the alcohol present in the raw spirit.

If the whole of the distillation fractions are taken for the average sample, the amount of fusel oil contained by it is 55 per cent., and the amount of alcohol nearly 100 per cent. of that contained in the raw spirit.

*Experiment with a Column.*—Thirteen layer formations. The first runnings were 3 litres (the amount of raw spirit was 95 litres). The next seven 10-litre fractions formed the average sample, and the rest the last runnings.

The raw spirit contained.....	0.127 per cent. vol. of fusel oil.
The first runnings contained..	0.037 " "
The average sample contained	0 " "
The last runnings contained..	1.314 " "

The composition of the whole of the distillate showed that there had been a loss of only 7 per cent. of fusel oil and 5 per cent. of alcohol, but that by the use of the column the whole of the fusel oil was retained in the first and last portions of the distillate, and there was a loss of 20 per cent. of alcohol. The result of all the experiments, then, appear to be that the process of Traube does not fulfil its purpose.

—A. L. S.

*A New Vegetable Ferment.* W. Sigmund. *Monatsh.* 11, 272—276.

A PAPER has recently been read before the Akademie der Wissenschaften at Vienna in which the author states that he has isolated an albuminous substance from the aqueous extract of rape seed, which has a specific action on fats, especially olive oil, decomposing them and liberating fatty acids. When its action was compared with that of ordinary egg albumen, it was found that 0.52 grm. liberated 9.6 mgrms. of oleic acid as against 1.1 mgrms. given by the latter. From this it appears to be a true ferment capable of decomposing fats.—B. B.

*The Examination and Valuation of Spirits.* W. Fresenius. *Zeits. Anal. Chem.* 29, 283—317.

See under XXIII., page 975.

*On some Essences used for Strengthening Spirituous Liquors and Ripening Artificial Brandies.* E. Poleske. *Proceedings of the Imperial Board of Health (Russia)*, 1890, 294.

*Examination of the Essences.*—Taste and smell, the latter especially when the essence is evaporated over the water-bath, will detect many ethers, also fusel oil, acetic acid, vanillin, &c. If the essence contains much alcohol dilution with an equal bulk of water will make it turbid, from separation of oils or resins if they be present. Dilution of the essence with water till it contains 10 per cent. alcohol and subsequent shaking with ether or chloroform will extract many substances, and these may be detected by evaporating the ether by a stream of cold air.

100—300 cc. of the essence (diluted, if necessary, to contain about 30 per cent. of alcohol) is distilled over wire gauze till about 80 per cent. of distillate (I.) is obtained, and a residue (II.) left. This distillate will contain the alcohol, volatile ethers, ethereal oils, fusel oil, part of the ananthic ether and volatile acids; when it reacts acid it is neutralised with decinormal potash and phenolphthalein, redistilled, and the residue mixed with residue II.

The neutral distillate is heated in a reflux apparatus with 2—4 grms. of potash for 2½ hours and distilled (distillate a, residue b). This distillate is made up to the original volume with water and serves for determining the alcohol and the fusel oil by Rose's chloroform method. The chloroform extract will contain any unsaponifiable ethereal oils which may be present, as well as the fusel oil; it is washed with water and quickly evaporated in a stream of cold air; oily drops will be left on the surface of the water, and these, if fusel oil be present, will smell strongly thereof and will give Uffelmann's methyl-violet reaction. A very

small quantity of fusel oil will, however, evaporate with the chloroform and the smell of the ethereal oil will become evident.

Residue *b* will contain the potassium salts derived from the ethereal salts; the corresponding acids may be liberated by distilling with phosphoric acid and steam; if ananthic ether was present some capric and caprylic acids will be obtained here, but most of them will be in residue II. To determine the ananthic ether the essence must be directly saponified, distilled, and the residue distilled with phosphoric acid. The solid (capric and caprylic) acids are filtered from the distillate, dissolved in alcohol, and titrated; again liberated, dissolved in ether, evaporated, and weighed. The lower acids in the filtrate are titrated with baryta, evaporated to dryness, and weighed; if the barium salts are not less than 0.2 grm. they may be separated by absolute alcohol after Luck (*Zeits. Anal. Chem.* 10, 185), and the formic acid determined by mercuric chloride or Menair's bichromate method (*Zeits. Anal. Chem.* 12, 398).

The cinnamic and benzoic acids are extracted together with the capric and caprylic acids from the distillate containing the latter, by ether. All are converted into the potassium salts and the fatty acids thrown out by calcium chloride; the filtrate is evaporated when the sparingly soluble calcium cinnamate separates.

The acids found in residue *b* will serve for the estimation of the rest of the ethereal salts.

Residue II. will smell of vanillin if this be present; shaking with ether and treatment with sodium bisulphite, after Tiemann's and Haarmann's method, will extract the vanillin. The residue from this ether extract will contain resins, such as capsicum, balsam of Peru, and spices. Sugar and caramel can be detected by tasting residue II. A tenacious froth produced by shaking, and an astringent irritating after-taste indicate saponin.

The following table shows the results given in the paper:—

## PATENTS.

*Improvements in or Relating to a Process for the Saccharification and Fermentation of Amylaceous Matter.* W. P. Thompson, Liverpool. From La Société Générale de Maltosa, Brussels, Belgium. Eng. Pat. 16,093, October 12, 1889. 4d.

THE use of ammonium or sodium fluorides or the double potassium sodium fluoride is recommended in saccharification or fermentation as an antiseptic. A quantity about 20 grms. per hectolitre is suitable. Almost any other fluoride may be used for the same purpose.—A. L. S.

*An Improved Process for Manufacturing Non-alcoholic Wine, and for Utilising a By-product.* E. Dean, Hastings. Eng. Pat. 16,105, October 12, 1889. 4d.

GRAPES are placed in a boiler and heated to 212° F. The juice is separated from the skin and stones, boiled, a little gum arabic added, put into hot bottles, and hermetically sealed up.

The stones are separated from the skin, which is chopped up and made into jam in the usual way.—A. L. S.

*Novel Construction or Arrangement of Condensing Cylinders used for Aërating Malt and other Liquors.* D. Wickham, Ware. Eng. Pat. 16,556, October 19, 1889. 6d.

THE apparatus consists of a cylinder with moveable ends, each having a packing joint which are kept in gas-tight contact with the cylinder by long bolts arranged on the outside of the cylinder from one head to the other. This arrangement is very easy to clean. The agitator shaft passes through the ends and is turned by a handle outside. The interior is tinned or silvered. To use the apparatus carbonic acid and the liquor to be carbonated is pumped into the cylinder until the necessary pressure is reached, the liquor stirred by the agitator and bottled by any suitable machine. —A. L. S.

*An Apparatus for Cooling and Aërating Hot Worts for the Production of Malt Liquors.* M. Hanford, Boston, U.S.A. Eng. Pat. 4982, March 31, 1890. 8d.

By converting hot wort into a fine spray and allowing the spray to fall a short distance through the air of the cooling room on to the cooler, it is quickly aërated and cooled. An apparatus for the purpose consists of a vertical tube with a conical-shaped deflector fitted to its end, leaving a small annular space between the end of the tube and the deflector through which the wort flows being converted into a fine spray thereby. This annular opening, if regulated to be of the correct size at the commencement, soon ceases to act properly owing to an accumulation of gummy matter, &c. For the purpose of preventing this, the conical deflector is fastened to one end of a lever pivoted in the centre, and to the other end of the lever a weight is fixed so that at the commencement of the operation the aperture is of the correct size. If the aperture become too small by an accumulation of gummy matter, the pressure exerted on the deflector by the liquid will be greater, and the consequence will be that the deflector will be forced further away from the end of the tube and the annular space be enlarged to the correct dimensions. In order that the deflector shall not stick, there is a stop which prevents it coming too close to the end of the tube. A cord is attached to the lever so that by pulling it the annular aperture may be temporarily enlarged for flushing.

—A. L. S.

*A New or Improved Process for Preventing and Arresting the Development of Acids during the Process of Malting Barley or other Malted Cereals, such as Rye, Oats, or Wheat, and the Storage of the same after having been Malted, and in the Infusion whilst Macerating or Infusing Malted Barley, for the Manufacture of Concentrated Extract of Malt, or for Ale Brewing Purposes, or for the Manufacture of Malt Vinegar.* W. Paterson, Glasgow, Eng. Pat. 6337, April 25, 1890. 6d.

THE finest barley is chosen and malted as usual, except that all water used is made alkaline by potassium or sodium carbonate, or kept neutral by finely-divided calcium carbonate. The malt is stored in air-tight iron tanks which are filled with carbonic acid gas. The malt when required for use is ground in the usual way and mashed in a tub from which either the air is exhausted by a vacuum pump or displaced by carbonic acid. The mash, if required for the manufacture of malt extract, is neutralised with sodium carbonate or bicarbonate, the wort filtered and evaporated in vacuo, the access of air to the wort at any stage being prevented.—A. L. S.

## XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

### (A).—CHEMISTRY OF FOOD.

#### PATENT.

*Improvements in Apparatus for Sterilising Milk and other Liquids, and for Drawing off or Decanting the same.* G. T. Redfern, London. From J. F. H. Gronwald, E. H. C. Oehlmann, and G. H. Nenhaus, Berlin, Germany. Eng. Pat. 11,554, July 23, 1890. 6d.

Two or three forms of the apparatus are described, but the following are the essential points common to all of them. The milk or other liquid is run into a number of chambers or vessels, which by their peculiar shape or arrangement offer a very large heating surface, so that the milk can be rapidly heated to the desired temperature, and the risk of its browning avoided. These vessels are enclosed in a large heating chamber, into which steam can be admitted, the pressure of the latter being regulated by a suitable valve. The vessel which is eventually to receive the milk is situated outside the chamber, and is connected with the milk vessels by means of a pipe. Air can enter or escape from it only by means of an air-filter. Before admitting the sterilised milk, this vessel is sterilised by blowing steam through it. Connexion with the external air is then cut off by closing various taps, the steam condenses, a vacuum is formed, and the milk is then admitted without coming in contact with the air.—F. W. T. K.

### (B).—SANITARY CHEMISTRY.

*The Pollution and Spontaneous Purification of Rivers.* Chem. Zeit. 14, 855.

At the annual meeting of the German Society of Gas and Water Engineers, Professor v. Pettenkofer read a paper with the above title.

No general statements can be made with regard to the spontaneous purification of rivers, but each case must be considered on its own merits. The great bulk of the sewage of Munich is conducted direct into the Isar. This is not considered to have any prejudicial effects on the inhabitants living on the banks of the river below Munich. The example of Rome, the sewage of which has run into the Tiber for more than 2,000 years, is quoted as upholding this opinion; it is also stated that the sewage of Hamburg has run into the Elbe for the last 40 years, and yet the water at Altona (40 miles below Hamburg) is

drinkable. The amount of organic matter introduced into the river by the Munich sewage amounts to 6 mgrms. per litre, and this is considered as insufficient to be hurtful. With respect to the danger which arises from the presence of pathogenic bacteria, it is known that for long the effluvia from hospitals and slaughter-houses has been allowed to pass direct into various rivers without ill effects, it is probable that these organisms do not find proper nourishment in the water, and are not able to hold their own in the struggle for existence, against the more numerous harmless bacteria. The spontaneous purification of rivers probably depends more on the velocity of the current than the volume of the water. It is probably unnecessary in many cases to pass the sewage through the land first, as under most circumstances it would do no harm if allowed to flow directly into the river.—A. L. S.

## XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

*Synthesis of Homopiperidine Acid and Piperidine Acid* S. Gabriel. Ber. 23, 1767—1773.

By oxidising acid derivatives of piperidine and decomposing the oxidation products with hydrochloric acid, Schotten obtained homopiperidine acid,  $C_5H_{11}NO_2$ , which he proved to have the constitution of a  $\delta$ -amidovalerianic acid,  $NH_2 \cdot CH_2 \cdot CH_2 \cdot CH_2 \cdot CH_2 \cdot COOH$ , and piperidine acid,  $C_6H_9NO_2$ .

The author has succeeded in preparing homopiperidine acid synthetically, in the manner described below, and has also proved that piperidine acid is  $\gamma$ -amidobutyric acid,  $NH_2 \cdot CH_2 \cdot CH_2 \cdot CH_2 \cdot COOH$ .

*Ethyl- $\gamma$ -phthalimidopropylmalonate—*

can be obtained by heating the sodium derivative of ethyl malonate with bromopropylphthalimide in alcoholic solution. The mixture is boiled for an hour, the alcohol and the unchanged ethyl malonate distilled with steam, and the residual oil separated or extracted with ether; the product thus obtained is dissolved in boiling light petroleum, from which it separates after some time in compact crystals, melting at  $46^\circ$ — $48^\circ$ . When this compound (5 grms.) is heated at  $180^\circ$ — $190^\circ$  for three hours with hydrochloric acid of sp. gr. 1.13 (25 cc.) it is decomposed into ethylchloride, carbonic anhydride, phthalic acid and the hydrochloride of homopiperidine acid ( $\delta$ -amidovalerianic acid); the amido-acid thus obtained is identical with the compound prepared by Schotten from benzoylpiperidine.

When the hydrochloride of piperidine acid, prepared from piperidylurethane by Schotten's method (Ber. 16, 643), is converted into the free acid, and a crystal of  $\gamma$ -amidobutyric acid placed in its saturated solution in alcoholic ether, a colourless crystalline powder, which shows all the properties of  $\gamma$ -amidobutyric acid, is obtained; piperidine acid is, therefore, identical with  $\gamma$ -amidobutyric acid.

Schotten drew attention to the fact that although  $\delta$ -amidovalerianic acid is harmless, its anhydride, piperidone, is a powerful poison; he also showed that piperidine acid has no poisonous properties. The author has found that pyrrolidone, the anhydride of piperidine acid, has a poisonous action very similar to that of piperidine.

—F. S. K.

*Conversion of Tropidine into Tropine.* A. Ladenburg. Ber. 23, 1780—1781, and 2225.

WHEN tropidine is treated with hydrobromic acid in the cold it yields small quantities of a base which is not volatile with steam, and which forms a crystalline platino-chloride

containing the same percentage of platinum as the corresponding salt of tropine; only a very small quantity of this non-volatile base is produced, most of the tropidine remaining unchanged, but when the reaction is carried out at a higher temperature a better yield is obtained.

The product, prepared in this way, decomposes on distillation and seems to contain bromine; when freed from halogen by means of silver oxide it yields a strong base which, on treatment with tropic acid and hydrochloric acid, gives a solution showing all the properties of atropine, and possessing like the latter a mydriatic action.

Further experiments have shown (Ber. 23, 2225) that the base prepared in the cold is in fact identical with tropine; its platino-chloride resembles that of tropine very closely and has practically the same melting point; it also forms a sparingly soluble cadmio-iodide and a deliquescent hydrochloride.—F. S. K.

*Oil of Nutmeg and Oil of Mace.* F. W. Semmler.  
Ber. 23, 1803—1810.

OIL of mace, which consists essentially of terpenes, has been shown by Wallach (this Journal, 1889, 635) to contain pinene and dipentene. Oil of nutmeg has been investigated by Gladstone, Wright, and others, and has been found to contain two terpenes,  $C_{10}H_{16}$ , a very little cymene, and an oil (myristiccol), boiling at  $212-226^\circ$ , to which Gladstone assigned the composition  $C_{10}H_{14}O$ , and Wright the composition  $C_{10}H_{16}O$ ; the latter also obtained from the oil a liquid of the composition  $C_{10}H_{16}O_2$ , boiling at  $260-290^\circ$ , whilst a solid stearopten myristicin which was isolated by John was proved by Flückiger to be myristic acid. According to Wright, oil of nutmeg also contains a non-volatile resin of the composition  $C_{10}H_{16}O_3$ .

The results of previous investigators being in many cases either doubtful or self-contradictory, the author has commenced an examination of these two oils.

Oil of nutmeg, as obtained from Schimmel and Co., is colourless and transparent and has a specific gravity of 0.8611 at  $15^\circ$ ; it consists of a mixture of various terpenes and does not contain cymene, myristiccol, or any oils of high boiling point.

Oil of mace, from the same firm, has a specific gravity of 0.9309 at  $14^\circ$ , and gives a green colouration with an alcoholic solution of ferric chloride; on cooling it to  $-10^\circ$  no solid substance is deposited. On fractional distillation under a pressure of 10 mm., 53 per cent. passes over below  $71^\circ$ ; this fraction consists of terpenes and contains pinene and dipentene as was shown by Wallach (loc. cit.). The portion passing over between  $71^\circ$  and  $114^\circ$ , which forms 15 per cent. of the whole, should, according to Wright, contain the myristiccol  $C_{10}H_{16}O$ , but it has not yet been investigated. The remaining 31 per cent. (which has not been distilled) is practically identical with an oil that is sold as "High-boiling portions of oil of mace." This commercial article is yellow, gives a green colouration with alcoholic ferric chloride, and contains myristicin (see below), which is deposited in small quantities on cooling to  $-17^\circ$ ; the specific gravity of the oil is 1.1303 at  $14^\circ$ , and it dissolves in concentrated sulphuric acid, yielding a clear red solution. Under a pressure of 10 mm. it begins to boil at  $124^\circ$ , and on fractional distillation the distillate is resolved into at least two substances, but when carefully distilled over excess of sodium, under reduced pressure, a colourless highly refractive oil passes over at  $142-149^\circ$  (10 mm.) and solidifies on cooling to a colourless crystalline mass. This crystalline substance has the molecular formula  $C_{12}H_{14}O_3$ , and is named by the author *myristicin*. It has an odour of nutmeg, melts at  $30-35^\circ$ , and has a specific gravity of 1.1501 at  $25^\circ$ ; on distillation over zinc dust it yields benzene, showing that it is an aromatic compound.

*Dibromomyristicin*,  $C_{12}H_{14}Br_2O_3$ , is obtained when myristicin is treated with bromine in carbon tetrachloride solution until the bromine ceases to be rapidly absorbed. It crystallises from boiling light petroleum in colourless needles and melts at  $105^\circ$ .

Oil of mace contains about 22 per cent. of myristicin.

—F. S. K.

*Coniceines.* E. Lellmann. Ber. 23, 2141—2142.

$\alpha$ -CONICEINE can be prepared, according to Hofmann, (1) by treating conydrine with hydrochloric acid; (2) by the elimination of hydriodic acid from the iodoconiine obtained by the action of hydriodic acid on conydrine; and (3) by the action of sulphuric acid on the bromoconiine in which the bromine atom is in combination with nitrogen.

The author's experiments have shown that these three methods all yield different coniceines, that prepared by the first method being probably the  $\alpha$ -compound. The bases obtained by the second and third methods, which are named  $\epsilon$ - and  $\delta$ -coniceine respectively, resemble the  $\alpha$ -compound in some respects, but differ from it in others.  $\alpha$ -Coniceine, for example, boils at  $158^\circ$ , and is hygroscopic;  $\delta$ - and  $\epsilon$ -coniceine boil at  $158^\circ$  and  $150-151^\circ$  respectively, and are not hygroscopic.  $\delta$ -Coniceine is levo-rotatory ( $-7^\circ 48'$ ), the  $\epsilon$ -base, on the other hand, is dextro-rotatory ( $42^\circ$ ). The hydrochloride of the  $\epsilon$ -base is very deliquescent, and that of the  $\alpha$ -compound moderately so, but the salt of the  $\delta$ -base is stable in the air. The picrate of  $\alpha$ -coniceine melts at  $224^\circ$ , that of the  $\delta$ -base at  $226^\circ$ , and that of the  $\epsilon$ -base at  $223-224^\circ$ ; the aurochlorides melt at  $196-198^\circ$ ,  $207^\circ$ , and  $178^\circ$  respectively, but the salt of the  $\epsilon$ -base does not decompose at its melting point, whilst that of the  $\delta$ -base undergoes slight, and that of the  $\alpha$ -base very considerable decomposition.—F. S. K.

*The Constitution of Apiol and of its Derivatives.* G. Ciamician and P. Silber. Ber. 23, 2283—2295.

PREVIOUS investigations of the authors have pointed out the analogy of apiol to safrol and methyl eugenol (this Journal, 1888, 399 and 583; and 1889, 1007). The present paper is a continuation of these researches. Isapiol, when oxidised by potassium permanganate in alkaline solution, behaves like all similarly constituted bodies, yielding, in addition to apioic acid, a ketonic acid. The latter is easily separated from apioic acid, owing to its ready solubility in water.

When reduced by sodium in alcoholic solution, isapiol behaves like isosafrol, two products resulting—a dihydro-isapiol,  $C_{12}H_{16}O_3$ , and a monovalent phenol,  $C_{11}H_{16}O_3$ . The dihydro-derivative is separated from the product of the reaction by treatment with water, when it rises to the surface and can be filtered off and recrystallised from alcohol, or be purified by distillation. The alkaline filtrate is extracted with ether after distilling off the alcohol, when the phenol is obtained as a thick yellow oil, boiling at  $277-278^\circ$ . It has the following constitution:—

Whilst isapiol and isosafrol are readily reduced as shown, apiol and safrol are practically unacted upon by sodium in alcoholic solution.

Ginsberg has shown (this Journal, 1888, 583) that isapiol when treated with bromine yields a tribromo-derivative, two of the bromine atoms of which are removed by treatment with zinc dust in alcoholic solution, whilst the third remains unchanged. A monobromo-derivative results. By treating isapiol in ethereal solution at  $-18^\circ$  with bromine, a dibromo-isapiol is formed, which melts at  $75^\circ$ . The dibromo-isapiol is decomposed by boiling water; treated with zinc dust in alcoholic solution, an oily product is formed which appears to differ from isapiol.

The authors have previously shown that apion is the dimethyl-methylene ether of a tetrahydroxyphenol apionol, and have succeeded in preparing apionol tetramethylether (this Journal, 1889, 1007). The four substituting groups in this ether, and therefore also in apionol, appear to have the relative positions 1, 2, 3, 4, whence apionol would have the constitution—

The two unsubstituted hydrogens are consequently in the 1:2 position. The former is obtained by treating apion in glacial acetic acid solution with nitric acid at  $-18^{\circ}$ , and forms yellow needles which melt at  $117^{\circ}$ — $118^{\circ}$ , and which are reduced to the latter by means of tin and hydrochloric acid. Diamido-apion forms prisms which melt at  $119^{\circ}$ , and yields azines with both di-acetyl and with di-benzil.

As to the constitutional formula of apion itself, it is evidently derived from 1, 2, 3, 4, tetrahydroxyphenol.

Eykmann (Ber. **23**, 857) has shown that the difference between apion and isapiol is due to the different structure of the  $C_3H_5$  group—the former containing the allyl group  $-CH_2 - CH = CH_2$ , and the latter the propenyl group  $-CH = CH - CH_3$ —C. A. K.

*Laurene.* E. Uhlhorn. Ber. **23**, 2346—2349.

THE author has studied the products obtained when Japan camphor is distilled with chloride of zinc, with a view of clearing up the conflicting statements as to the nature of the hydrocarbons formed. He finds that the fraction boiling between  $180^{\circ}$ — $195^{\circ}$  contains two ethylxylenes. The ortho body—

and the para body—

the fraction from  $185^{\circ}$ — $187^{\circ}$  probably contains the ethyl-meta-xylene—

Several derivatives of these hydrocarbons are described. —C. A. K.

*Propylxylenes.* E. Uhlhorn. Ber. **23**, 2349—2351.

*Propylortho-xylene* [ $CH_3 \cdot CH_3 \cdot C_3H_7 = 1:2:4$ ] prepared by Fittig's method from monobromo-*o*-xylene and propyl bromide, boils at  $209^{\circ}$  and remains liquid at  $-20^{\circ}$ . Its sulphonic acid forms thin needles and yields characteristic barium, magnesium and sodium salts. The sulphamide, sulphanilide, and tribromo-propyl-xylene are described. The hydrocarbon yields para-xylic acid (melting point  $162^{\circ}$ ) on oxidation.

*Propyl-meta-xylene* [ $CH_3 \cdot CH_3 \cdot C_3H_7 = 1:3:4$ ] boils at  $205^{\circ}$ — $208.5^{\circ}$ , and remains liquid at  $-20^{\circ}$ . Similar derivatives to the above are described, also the trinitro derivative of the hydrocarbon. On oxidation xylic acid (melting point  $126^{\circ}$ ) results.

*Propyl-para-xylene* [ $CH_3 \cdot C_3H_7 \cdot CH_3 = 1:2:4$ ] boils at  $206^{\circ}$ — $207^{\circ}$  and remains liquid at  $-20^{\circ}$ . Similar derivatives to the above are again described.

The isopropylxylenes could not be prepared directly by Fittig's method, but the meta product, isopropyl-meta-xylene [ $CH_3 \cdot CH_3 \cdot CH(CH_3)_2 = 1:3:4$ ] was obtained from isopropylbenzene by converting this into the mono-bromo-derivative and then substituting the bromine in the resulting monobromopara-isocymol by methyl. The hydrocarbon boils at  $194^{\circ}$ — $195^{\circ}$ ; its sulphonic acids and salts thereof are described, also the sulphamide, sulphanilide, tribromo- and trinitro derivatives.—C. A. K.

*Melting Points of Quinine, Cinchonidine, and their Isomerides.* O. Hesse. Annalen, **258**, 133—144.

THE author has repeated his determinations of the melting points of these substances (Ann. **135**, 327; **176**, 207) using Roth's apparatus (Ber. **19**, 1970; this Journal, 1886, 617). Anhydrous quinine obtained by drying the trihydrate over sulphuric acid and heating to  $115^{\circ}$  or  $120^{\circ}$ , melts at  $171.2^{\circ}$ — $172^{\circ}$ , when obtained by heating the benzene compound  $C_{20}H_{24}N_2O_3 \cdot C_6H_6$  to  $120^{\circ}$ , it melts at  $171.6^{\circ}$ — $172^{\circ}$ . The anhydrous isomeride formed by the prolonged heating of solutions of quinine in dilute alcohol, &c. at  $30^{\circ}$ , and which may be termed quinine anhydride or *Homo-quinine* melts at  $174.4^{\circ}$ — $175^{\circ}$ . It is reconverted into quinine by the prolonged action of dilute sulphuric acid.

Cinchonidine melts at  $202^{\circ}$ — $202.8^{\circ}$ , and is readily converted into its isomeride homocinchonidine, which melts at  $207^{\circ}$ — $208.2^{\circ}$ . The latter may be reconverted into cinchonidine by repeated crystallisation from dilute sulphuric acid (Ann. **205**, 194; this Journal, 1888, 350).

The  $\beta$ -cinchonidine obtained by the author by the action of hydrochloric acid on cinchonidine (Ann. **205**, 327) melts at  $206^{\circ}$ — $207^{\circ}$  but acquires a brown colouration. In an acid solution it polarises more strongly than homocinchonidine; the sulphate resembles the homocinchonidine salt, and may be similarly converted into the cinchonidine compound, but it is more soluble in water. It may, therefore, be assumed that the first product of the action of hydrochloric acid (sp. gr. = 1.125) upon cinchonidine at  $140^{\circ}$  consists of homocinchonidine, which is further partially converted into apocinchonidine. In the presence of concentrated sulphuric acid only the first change takes place.

—S. B. A. A.

*Conversion of Compounds of the Terpene Group into Metaxylene.* O. Wallach. Annalen, **258**, 319—340.

CINEOLIC acid,  $C_{10}H_{16}O_3$  (this Journal, 1888, 586), is a dibasic acid; its methyl salt,  $C_8H_{14}O(CO_2CH_3)_2$ , melts at  $31^{\circ}$ ; the anhydride,  $C_{10}H_{14}O_3$ , prepared by distilling a solution of the acid in acetic anhydride, and removing the excess of solvent in a vacuum at a low temperature, melts when pure at  $77^{\circ}$ — $78^{\circ}$ , boils at  $157^{\circ}$  under a pressure of 12—13 mm., dissolves in chloroform and benzene, separating on addition of light petroleum in long needles. It is reconverted into the acid by boiling with water. By dry distillation cineolic anhydride is decomposed according to the equation—

cineolic acid on the other hand is partially converted into the anhydride and partly decomposed into carbonic anhydride and a monobasic acid,  $C_8H_{14}O_3$ .

The compound  $C_8H_{14}O$  is a liquid with a pleasant penetrating odour, boiling at  $173^{\circ}$ — $174^{\circ}$ , V.D. = 4.19. Sp. gr. at  $20^{\circ}$  = 0.8530. Index of refraction  $n_D = 1.44003$ . It is an unsaturated compound which absorbs bromine and the halogen acids and is oxidised in the cold by potassium permanganate with evolution of carbonic anhydride; in contact with solid caustic potash it becomes warm and is partially resinified; with sodium bisulphite it forms a crystalline unstable addition compound. It thus appears to contain doubly linked C atoms and a ketonic (or aldehydic?) group. When it is heated with dry zinc chloride first at  $95^{\circ}$  and subsequently at  $145^{\circ}$ , the product may be separated by fractionation into two portions, boiling at  $132^{\circ}$ — $134^{\circ}$  and  $280^{\circ}$ — $285^{\circ}$  respectively. The fraction (132—134) has the formula  $C_8H_{12}$ , its odour recalls that of xylene, its sp. gr. at  $20^{\circ}$  = 0.8275, index of refraction at  $20^{\circ}$   $n_D = 1.4675$ , V.D. = 3.74. Like the terpenes it combines with the halogens and halogen acids, but it differs from them in its conversion into nitro-xylene by the action of nitric acid.

The fraction ( $280^{\circ}$ — $285^{\circ}$ ) contains a polymeride having the formula  $C_{16}H_{24}$ . The identity of this xylene is established by the coincidence of the melting points of a large series of nitro- amido- and acetyl- derivatives with the corresponding compounds prepared from metaxylene. The authors regard cineol as having the constitution—

cineolic acid thus becomes—

and the anhydride—

the compound  $C_{10}H_{16}O$  which should accordingly have the constitution—

appears, however, to open out into the unsaturated ketone  $CH_3 \cdot CO \cdot CH_2 \cdot CH : CH \cdot CH(CH_3)_2$  in a manner analogous to the formation of pinacolone from pinacol. The closed xylene chain is re-formed when water is eliminated from the molecule by the combination of the oxygen in the CO with two hydrogen atoms from the  $(CH_3)_2$ .—S. B. A. A.

*The so-called "Massoyene."* O. Wallach. *Annalen*, **258**, 340—343.

Woy (*Archives der Pharm.* **228**, 22) obtained from Massoy bark a new terpene boiling at  $172-173^\circ$  having a specific gravity of 0.8581 at  $18^\circ$  and yielding a bromide melting at  $93^\circ$ . The author finds that by steam distilling and fractionation this terpene a considerable proportion passes over between  $160-165^\circ$ , this fraction forms like pinene a nitrosochloride, which yields a nitrobenzylamine melting at  $123^\circ$ ; it is converted by alcoholic potash into the nitrosopinene, melting at  $133^\circ$ . The other fraction boils between  $170^\circ$  and  $175^\circ$ , and yields on bromination in a glacial acetic acid solution dipentenetetra bromide melting at  $123^\circ$ , together with some impure by-products with inconstant melting points ( $97-104^\circ$ ) which probably consist of a mixture of limonene and dipentene tetra bromides; no bromide melting at  $93^\circ$  was obtained. The combinations with the halogen acids  $C_{10}H_{16} \cdot 2 HCl$ , &c. obtained by Woy render it probable that the second terpene in massoy-bark oil is limonene containing a small proportion of dipentene; the presence of limonene is also indicated by the melting point ( $93^\circ$ ) of the nitrolamine obtained from the fraction ( $170-175^\circ$ ). Woy's massoyene thus appears to be a mixture of limonene, pinene, and dipentene.—S. B. A. A.

*Pinene.* O. Wallach. *Annalen*, **258**, 343—347.

CHEMICALLY pure pinene may be prepared by treating pinenenitrosochloride obtained as described (*Ann.* **253**, 251; this *Journal*, 1889, 959) with aniline (*Ann.* **252**, 132), steam distilling the product and agitating the distillate in the cold with water and excess of acetic acid; the light oil which separates is thoroughly washed with water and acetic acid. The following reaction takes place:—

Pinene prepared in this way boils at  $155-156^\circ$ , sp. gr. = 0.858 at  $20^\circ$ , 0.854 at  $25^\circ$ . Index of refraction  $n_D = 1.46553$  at  $21^\circ$ . It is inactive to light and remains so after treatment with hydrogen chloride. It is not therefore like the so-called "inactive pinene," an accidental mixture of nearly equivalent quantities of the dextro- and levo-gyrate varieties in which the components are distinguishable by the action of reagents. Inactive pinene combines with nitrosyl chloride like the active modification, pinol also occurring as a by-product (*Ann.* **253**, 249).

By reducing a glacial acetic solution of nitrosopinene,  $C_{10}H_{15}NO$ , with a solution of hydriodic acid in the same solvent or with zinc dust an oily base  $C_{10}H_{15}NH_2$  is obtained. This compound smells like borneol, distils without decomposition at  $98-99^\circ$  under a pressure of 22—23 mm. and between  $207-208^\circ$  at the ordinary pressure. It differs greatly from the isomeric carvylamine (*Ber.* **20**, 486) and from amidoterebenthene (*Gazz.* **16**, 228, 341), the hydrochloride of the new base melting at  $221-222^\circ$  and the benzoyl derivative at  $116^\circ$ . The sulphate, unlike the amidoterebenthene salt, is a stable well-crystallised compound.—S. B. A. A.

*On the Physiological Action of Uranium.* J. Woroschilsky. *Chem. Zeit.* **14**, 1002—1003.

SINCE the discovery of uranium about 100 years ago by Klaproth, its action on the animal organism has been frequently investigated, the first to do this being Gmelin, in 1824. The author has recently studied the physiological action of this element, and has verified and extended the observations of previous experimenters. The action of it has been tried under the most varied conditions on mammals, birds, frogs, and worms; the results show that uranium, however administered, is a very poisonous metal. Uranium in fact has been included in the list of poisonous substances in the Russian pharmacopœia.—A. W.

*Artificial Musk.* A. Baur. *Chem. Zeit.* **14**, 1094—1095.

THIS new commercial product is chemically quite distinct from real musk, as it is a nitro-derivative of isobutyltoluene. The latter hydrocarbon, which is also found in the so-called essences of rosin, is best prepared by Friedel and Crafts' method. The chief product is a meta derivative. This is nitrified with a mixture of strong nitric and sulphuric acids first in the cold and finally by heating on the water-bath for 24 hours. The nitro compounds produced are separated in the usual manner, and again nitrified as above to ensure complete conversion into the trinitro-derivative. The latter is finally crystallised from alcohol, when yellowish white needles melting at  $96-97^\circ$  are obtained, insoluble in water and possessing a distinct smell of musk. By acting on a solution of isobutyltoluene in glacial acetic acid with nitric acid the mononitro-derivative is produced which has an unpleasant smell and may be converted by further nitration into the trinitro-derivative. The former can be distilled with aqueous vapour; it is an oil which distils in vacuo at  $160-162^\circ$ .

Hepp has examined the physiological action of artificial musk, and finds that large quantities even are without effect on rabbits.

Isobutylmetaxylene also gives a trinitro-derivative possessing a musk-like smell, but neither as strong nor as pleasant as the trinitro-derivative of the first-mentioned hydrocarbon. (See following abstract; also this *Journal*, 1889, 1004.)—A. R.

*Musk.* *Monit. Scient.* 1890, **4**, 718—721.

**I. NATURAL MUSK.**—Musk is a secretion of the male musk rat (*Moschus Moschiferus*). It occurs in a small pouch which is situated below the stomach, and furnished at the posterior end with a small duct through which the musk is discharged. The quantity of musk found in the pouch is very various; 28 grms. may be considered the average quantity in an adult animal. Other animals, such as the civet, &c., and some plants, as *Adora moschatellina*, &c., yield similar substances.

Musk is a brownish slimy solid, with a sharp, slightly bitter taste and a disagreeable odour when strong, which becomes pleasant on dilution. It is a very complex body, containing nearly half its weight of water. It occurs in commerce both in the pouches and in bulk. The price is subject to considerable variations, Nankin musk being the most valuable. It is often adulterated, frequently by introducing foreign bodies into the pouches to increase their weight, and sometimes by perforating the pouches and dissolving out some of the substance. These falsifications are, however, easily detected. All pouches which show any sign of having been tampered with may be considered as adulterated. Musk in the bulk is much more easily adulterated; to determine if this is so, a little of the substance is warmed with glycerin or turpentine, and on cooling observed under the microscope. Pure musk forms a mass of yellow granules easily distinguished from any foreign matters which may have been added. It contains 45—46 per cent. water, and yields on incineration 4—6 per cent. grey ash; any divergence from these numbers indicate adulteration. Blood and meat are often added; these may be detected by a microscopic examination.

**H. ARTIFICIAL MUSK.**—Schauffer and Hupfeld patented a process in 1888 (this Journal, 1890, 102) for preparing artificial musk. Three kilos. of dimethyl benzene, 2 kilos. of isobutyl alcohol, and 9 kilos. of zinc chloride are heated together in an enclosed vessel for 7—8 days. The product is distilled, the fraction passing over  $198^{\circ}$ — $230^{\circ}$  only being kept and nitrated by fuming nitric acid. The product is washed and dissolved in alcohol, and crystallised from the solution. Its formula is  $C_{12}H_{16}NO_2$ . Another method is to use toluene or xylene with isopropyl or isosamyl alcohol and zinc chloride, and proceed as above.

Baur's patent (this Journal, 1889, 1004) consists in the preparation of meta-methyl-isobutyl-benzene by acting on isobutyl chloride by toluene in the presence of aluminium chloride and nitrating the product. Artificial musk is not a very satisfactory preparation, and its use is only limited.

To distinguish between natural and artificial musk, use is made of the property which sulphate of quinine possesses of destroying completely the odour of artificial musk without affecting in any way the natural product. Other bodies, such as bitter-almond oil, and all bodies containing benzoic aldehyde or hydrocyanic acid, possess the same property.—A. L. S.

*On Orcine.* A. Donner. Pharm. Zeit, 1890, 418.

See under XXIII., page 974.

*On Strychnine.* H. Beckurts. Arch. Pharm. 1890, 313.

PURE strychnine melts at  $265^{\circ}$ . The ferrocyanide is gradually converted by the action of light and air into the ferricyanide. The monobromide is prepared by adding 1 mol. of bromine in aqueous solution to 1 mol. of strychnine hydrobromide. On adding ammonia it is precipitated and on recrystallising from alcohol melts at  $222^{\circ}$ . The hydrochloride, hydrobromide, and nitrate of strychnine crystallise without water, the sulphate with 7 mols. of water. Bromostychninemethylodide, the ammonium base, nitro-bromostychnine, amidobromostychnine, and bromostychninedibromide are also described.—A. R.

*On Brucine.* H. Beckurts. Arch. Pharm. 1890, 426.

On adding an aqueous solution of 1 mol. of bromine to 1 mol. of brucine hydrobromide a violet precipitate is first formed, which changes through brown to a pure yellow. After washing and drying over sulphuric acid it is found to have the composition of a brucine tribromide or hydrobromide of dibromobrucine. Strychnine under the above conditions (see previous abstract) gives a monobromide. By shaking brucine with chlorine water a dark red powder is obtained, dichlorobrucine.—A. R.

*Report on Volatile Oils and Essences.* Relazione nel Lab. Chim. Centr. delle Gabelle, 119—121.

THE Custom house tariff distinguishes between "an essence properly so called" (i.e., an essential oil), and "an alcoholic essence." The latter is classed as alcoholic perfumery, or aromatic alcohols, and pays the surcharge on the spirit. The following rapid and sufficiently exact method for the estimation of the alcohol is proposed. To 4—5 cc. of the essence to be examined an equal volume of distilled water and of a mixture of two-thirds glycerol with one-third water is added and the whole allowed to stand. If alcohol is present there is found a milky turbidity in the layer below the essential oil, while the diminution of volume of the oil is approximately equal to the volume of the alcohol added.

Analyses are given of five disputed samples, and allusion is made to certain samples of essences of geranium and rose destined for the State manufacture of tobacco.—V. H. V.

*A New Monobromocamphor.* J. E. Marsh. J. Chem. Soc. (Trans.), 1890, 828—833.

$\beta$ -MONOBROMOCAMPHOR is best prepared by the action of bromine on camphor in presence of alcohol. The ordinary or  $\alpha$ -monobromocamphor is also formed, the two being

separated by fractional crystallisation from alcohol in which the  $\beta$ -compound is more soluble. When bromine acts on camphor in presence of alcohol, the substitution appears to take place at once without formation of the additive compound  $C_{10}H_{16}OBr_2$ , whereas when bromine acts on camphor alone, the additive compound formed at first decomposes on raising the temperature with evolution of hydrobromic acid. By the latter method, on distillation, a liquid is obtained boiling at  $160^{\circ}$  under 20 mm. pressure, and containing an amount of bromine midway between mono- and dibromocamphor.

$\beta$ -monobromocamphor after distillation in vacuo forms, on solidifying, an almost transparent mass, easily breaking up into a soft granular powder, very different in appearance from the hard crystals of the ordinary modification. The rotatory power is for  $[\alpha]_D = +34.9^{\circ}$ , the ordinary modification giving  $[\alpha]_D = +139^{\circ}$ . When distilled under ordinary pressure the new isomer begins to boil at  $250^{\circ}$  and distils fairly constantly at  $265^{\circ}$ . The distillate crystallised from alcohol gives the hard crystals characteristic of the ordinary modification. It is thus evident that the  $\beta$ - is converted into the  $\alpha$ -modification by distilling under ordinary pressure, while no change is effected by distilling in vacuo.—J. B. C.

#### ERRATUM.

For the two constitutional formulæ given in the May number of this Journal, page 541, top of second column, read respectively:—

## XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

*Etching on Glass by Photomechanical Processes.* A. Müller-Jacobs. Zeits. f. angew. Chem. 1890, 451—453.

THE photomechanical processes for etching on glass which are already known are either applicable only to fine subjects or present great practical difficulties when applied on a large scale. The author's process is based on the fact that when films of the resinat colours (this Journal, 1889, 770) are exposed to light they undergo change which, although almost invisible, is rendered evident by their behaviour towards various reagents. The dyestuff separates from the metallic resinate, and can be removed by means of alcohol or even hot water, in which it was previously insoluble, or can be bleached by reagents which had no action on it before exposure to light. After the action of the bleaching agent or solvent there is left a film of the metallic resinate which is insoluble in benzene, but can be removed by the action of oxidising agents.

When an exposed film is treated with benzene previously mixed with a large proportion of turpentine, the insolated portions remain undissolved whilst the unexposed parts pass into solution, the action of the solvent being inversely proportional to the action of the light. By this mode of development, as well as by treatment with oxidising agents, the gradations of the object which has been copied can be reproduced. Development by oxidation yields a positive image and development by benzene and turpentine a negative image. Development similar to that produced by oxidation is obtained when the plate is merely heated.

The exposed portions of the film which have not been affected by the developer offer great resistance to the action of acids, and are impermeable to them to an extent depending on the time of exposure. It follows that heliogravures on metal or glass can be produced by means of the resinat

colours, the resins themselves providing the necessary grain. The adhesion of the film of resinate to the glass is secured by mixing the benzene solution of the resins with india-rubber solution, a treatment which at the same time improves the grain. If too much india-rubber is applied, the sensitiveness is reduced; if too little, there is a tendency for the film to leave the glass.

*Preparation of the Sensitive Resinate.*—100 grms. of clear colophony are boiled with 10 grms. of sodium hydroxide, 33 grms. of crystallised sodium carbonate, and 1,000 cc. of water for two hours. 1,000 cc. of water is then added and the liquid is mixed with a filtered solution of 7.5 grms. of methyl-violet 3 B. (methyl-green, magenta, safranin, rhodamine, auramine, chrysoidine, Nile blue, Victoria blue, &c.) in about 500 cc. of boiling water. The resinate colour is precipitated by gradual addition of a solution of 60 grms. of magnesium sulphate, well washed, and dried at 60°–80°.

*Preparation of the India-rubber Solution.*—50 grms. of caoutchouc are digested with 4,000 grms. of carbon bisulphide for a long time, then heated in a water-bath until about half the bisulphide has distilled off, and pure benzene is added in sufficient quantity to make the total weight 3,333 grms.

*Preparation of the Sensitive Film.*—20 grms. of magnesium resinate violet, 8 grms. of the resinate green, 8 grms. of the resinate chrysoidine, and 4 grms. of the resinate magenta are dissolved in 130 cc. of pure benzene and 70 cc. of chloroform, and the solution is mixed with 120 cc. of the caoutchouc solution. After standing 8 days the mixture is filtered through cotton-wool and kept in the dark.

Well-cleaned glass or metal plates are coated with the mixture, dried for six hours, and exposed under a negative to direct sunlight, the time of exposure varying from 15 minutes to 3 hours. Red resinate colours increase the sensitiveness, blue and green colours reduce it. For deep etching thin films and long exposures are required.

The exposed plate is allowed to cool in the dark, and is then developed with a mixture of 1 part of benzene and 3 parts of turpentine (in summer, 1:4) at the ordinary temperature in the same way as a carbon print. When development is complete the plate is washed with light petroleum, the edges are coated with asphalt and the etching conducted in the usual manner. For matt etching on glass fuming hydrofluoric acid mixed with 10 per cent. of water may be used. If the action of the acid is continued too long the grain is destroyed and no matt surface is obtained, especially if the exposure has been short and the development has been carried too far. For deep etching an exposure of several hours is required.

When the plate is exposed under a negative, developed with benzene, and etched, and some colouring matter, such as white lead, is rubbed in the etched portions, an image is obtained, which, when placed against a black background, shows as a very clear diapositive. Instead of white lead, glass colours may be used and can afterwards be burnt in.

—C. H. B.

## PATENTS.

*New or Improved Lifters for Photographic Plates, Papers, and Films.* T. Stanway, Hauley. Eng. Pat. 16,528, October 19, 1889. 6d.

A PLAT or ribbon-like piece of ebonite, vulcanite, metal or other suitable material is bent into a loop of such form that it readily fits the corner of a photographic plate, and at the same time has a handle or finger-hole by which it can be lifted. Two such holders are used and they are applied to two diagonally opposite corners of the plate. Paper and films are placed on glass plates of suitable size, and at the corners to which the holders are not applied the paper or film is kept in contact with the glass by means of small india rubber bands.—C. H. B.

*An Improved Method of Preparing Photographic Plates of Mica.* E. Edwards, London. From O. Moh, Goerlitz, Germany. Eng. Pat. 11,104, July 16, 1890. 4d.

PLATES or sheets of mica are treated with a solution of chrome alum mixed with gelatin, in order "to remove mineral grease," and are afterwards coated with gelatinobromide emulsion in the usual way. The preliminary treatment with chrome alum and gelatin makes the emulsion adhere firmly to the mica.—C. H. B.

## XXII.—EXPLOSIVES, MATCHES, Etc.

*Report on the Circumstances attending an Explosion of Fireworks at Mr. James Pain's Firework Factory, near Mitcham, July 6, 1890.* Col. V. D. Majendie, C.B.

IN this report Colonel Majendie draws attention to the fact that the explosion did practically no damage beyond the building in which it occurred, even although more than three tons of fireworks of the most explosive character were contained in it, and the distance between the destroyed building and the other parts of the factory were moderate. This he considers shows the advantage of having such factories laid out on intelligent principles and with due regard to the risks inseparable from this class of manufacture.

There were present in the magazine three classes of fireworks more or less liable to spontaneous heating with a risk of ignition, viz., gerbes, blue stars, and asteroids and green lances. The blue stars and asteroids both contained "Chertier's copper," which is very liable to become acid, and although the samples of these fireworks examined were neutral this ingredient is liable to dangerous change during keeping, and ought not to be employed in firework mixtures. Chertier's copper is a mixture of potassium chlorate and copper sulphate, which has been moistened with ammonia and dried. When freshly made it is alkaline, but in time loses ammonia and becomes acid.

The gerbes also are liable to heating when damp, and although they are not likely to ignite spontaneously, the heat evolved might greatly endanger the stability of other fireworks in their neighbourhood. The gerbes contained iron filings, and although the filings have a protective coating of marine glue or similar composition, an elevation of temperature occurs when they are moistened. Although these fireworks just referred to are undoubtedly dangerous and might give rise to an explosion, in this particular instance the evidence goes to show that the accident may be referred to the spontaneous ignition of one of the green lances.

A few days after this accident a fire broke out in the same factory by the observed spontaneous ignition of one of the green lances, identical with those in the magazine. These lances contained "white" and "green fire" mixtures, the former consisting of potassium nitrate, flowers of sulphur, and antimony sulphide; the latter of barium and potassium chlorates, shellac, and charcoal. Dr. Dupré points out that "kept separate, neither of these mixtures would be liable to spontaneous decomposition, but when brought into contact they become dangerous. If these lances are filled with great care so that the two compositions are in contact only at the sectional area along which they touch, the danger is reduced to a minimum, though not perhaps wholly absent. But if, during the filling in of the two compositions, one upon the other, any intermixture takes place at the junction, a condition of things will be brought about which, under favourable conditions as to temperature, moisture, and retention of heat is certain, sooner or later, to lead to spontaneous ignition."

Several lances were cut open very carefully and in most cases the filling had been done with great care, but in one

case decided intermixing had taken place, and thus formed (flowers of sulphur and barium chlorate) one of the most dangerous firework compositions. Col. Majendie trusts that the lessons which this accident are calculated to teach will induce firework makers to exclude from their factories those particular elements of risk of which this accident affords a further and striking illustration.—W. M.

## XXIII.—ANALYTICAL CHEMISTRY.

### APPARATUS.

*Sulphuretted Hydrogen Apparatus.* H. Wilde. Chem. Zeit. **14**, 905—906.

The apparatus shown in the figure resembles in principle that previously described (this Journal, 1888, 523) by the author in conjunction with Pollak.

SULPHURETTED HYDROGEN APPARATUS.

The solid material, *e.g.*, ferrous sulphide, is placed in *a* and the acid in *b* and *c*. By opening a stopcock on *a1* (not shown) acid finds its way to the small hole at the top of the tube *b1* and trickles down causing a steady evolution of gas; *c* should be big enough to take any overflow from *b* consequent on closing *a1*. The spent liquor can be forced out at *a2* without dismounting the apparatus. To give a regular stream of gas the hole at the top of *b1* should be small, 1 mm. sufficing for a supply of 100 litres per hour; *b1* itself on the contrary must be wide to allow of the unhindered flow of acid downwards; 2 cm. is a suitable width.—B. B.

*Apparatus for Drying Substances in a Rarefied Atmosphere.* D. Sidersky. Zeits. Anal. Chem. **29**, 280—282.

*A* is a double-walled copper cylinder about 30 cm. high and 26 cm. diameter; the inside ends are flat but the outside

ends are arched. The door *B* is a thick glass plate and closes hermetically against an india-rubber washer. Water is poured in through the funnel opening *c*, which is then

DESICCATION IN A RAREFIED ATMOSPHERE.

closed with a cork having a long glass tube running through it to act as a condenser, and when it has been brought to the boiling point by the burner *b*, the air in *A* is rarefied by connecting the stopcock *p* with an aspirator. Should it be desirable to use a current of air the stopcock *r* can be opened and air drawn through the purifier *S*.—A. G. B.

*An Improved Apparatus for Decompositions in the Cold and under Diminished Pressure.* J. W. Brühl. Ber. **23**, 1460.

This is an improvement on an apparatus devised by the author (Ber. **22**, 236) for diazotising, for preparing leuco-compounds, and for the formation and separation of crystalline substances at any temperature, and in an atmosphere of any gas.

It consists of a cylindrical glass vessel closed at *a* with a glass cap ground on, and communicating at the base with a long tube, the entrance to the tube being closed by a platinum cone, or in its latest form by a glass or earthenware marble *b*. At the base of the tube, which is considerably contracted, *c*, a glass stopcock, is attached with rubber tubing.

Marbles varying in size from a cherry upwards may often be used with ordinary funnels, with or without a pump to replace filter plates, and give excellent results even with finely divided crystals.—F. H. L.

### INORGANIC CHEMISTRY.— QUALITATIVE.

*Tables for the Rapid Determination of the Common Minerals.* A. J. Moses. *School of Mines Quarterly*, **11**, 334—355.

THE two general methods for the rapid determination of minerals are those of von Kobell (Munich, 1884), and Weisbach (Leipzig, 1886); in both there is first a division into minerals of metallic lustre and minerals of non-metallic lustre, but in the one they are then grouped by their behaviour before the blowpipe and with acids, whilst in the other the classifying characters are the external signs of hardness, colour, streak, tenacity, &c. The author now combines, in a series of tables both systems of examination.

—T. L. B.

*On the Presence of Boracic Acid in Caustic Alkalis.* F. P. Venable and J. S. Callison. *Journ. Anal. Chem.* 1890, 196.

SEVERAL samples of caustic alkalis from Schuehardt, Marquart, and Trommsdorf described as chemically pure, were found to contain boracic acid. Meissl's method for determining boracic acid in milk was employed, *i.e.*, the alkalis were just saturated with acid in a platinum dish, the salts moistened with a little dilute hydrochloric acid (1:100), a few drops of tincture of turmeric added and then evaporated to dryness. Traces of boric acid causes a cherry or cinnabarred colouration. The flame test was also used. From the degree and delicacy of the reaction, it may be assumed that the quantity of boracic acid in the alkalis exceeded 1 per cent. This should be taken into account in quantitative determinations of boracic acid as caustic potash is frequently employed in them.—A. R.

*The Action of Zinc on Dilute Sulphuric Acid.* F. Püllinger. *J. Chem. Soc. (Trans.)* 1890, 815—827.

See under X., page 946.

### INORGANIC CHEMISTRY.— QUANTITATIVE

*On a Source of Error in Determinations of Sulphuric Acid.* E. von Meyer. *J. prakt. Chem.* **42**, 1890, 270.

HOLTZWART found, in the author's laboratory, that during the evaporations of a large volume of liquid over a gas flame, appreciable quantities of sulphuric acid were derived from the gas and collected in the liquid. Two litres of pure water were evaporated on a high-standing water-bath, heated over the gas, to a volume of 50 cc., an operation that took six hours. It was then found to yield 0.0426 grm. of  $\text{BaSO}_4$ , equal to 0.01462 grm. of  $\text{SO}_3$ , or 0.00731 grm. per litre. When the same volume was evaporated by distillation, no trace of sulphuric acid was found.

A similar experiment has been repeated by Bechert, at the author's request. One litre of pure water was gradually evaporated in a platinum dish, always keeping about

40—50 cc. water in the dish, over a small Bunsen flame. The time required was 12 hours. The residual water yielded 0.0309 grms. of  $\text{BaSO}_4$ , equal to 0.0106 grm. of  $\text{SO}_3$ . This relatively larger amount than found by Holtzwardt, is explained by the longer time the evaporation required. These observations point to the necessity of precaution being taken in water analyses and in all sulphuric acid estimations in which a large volume of liquid has to be evaporated.—H. S. P.

*Valuation of Zinc Dust.* G. Klemp. *Zeits. Anal. Chem.* **29**, 253—266.

THE author has devised a process for the above purpose which depends on the power of zinc to reduce potassium iodate to potassium iodide in an alkaline solution; when the solution is afterwards acidified iodine is liberated by the interaction of the iodine and hydriodic acids, and is distilled off from the reaction mixture into potassium iodide solution, and titrated with thiosulphate. The details of the method are as follows:—

0.5—1 grm. of the well-mixed zinc dust is weighed in a tube and poured into a 200 cc. stoppered flask, the tube being again weighed. For every 0.1 grm. of zinc present, 10 cc. of a solution of alkali (containing 370 grms. of potassium hydroxide, or 300 grms. of sodium hydroxide per litre) and 3 cc. of a solution of potassium iodate (containing 15.25 grms. of potassium iodate per 300 cc.) are measured into a beaker and then poured into the flask. Some glass beads are added, and the flask stoppered and shaken for five minutes in the cold, no advantage being gained by heating it; its contents are then washed into a 250 or 500 cc. flask, and made up to the mark with water. 100 cc. are now pipetted into the retort of a Töpfer's apparatus (*Zeits. Anal. Chem.* **26**, 293), dilute sulphuric acid is added and the apparatus filled with carbonic anhydride. A solution of potassium iodide is placed in the receiver and the retort heated, at first gently and then more strongly till the contents are perfectly colourless; the stream of carbonic anhydride is continued throughout the distillation, which generally occupies about 20 minutes. The solution of iodine in potassium iodide is then transferred from the receiver into a flask, a standard solution of sodium thiosulphate added in slight excess, and the excess titrated back with weak standard iodine solution, starch being used as an indicator. After correcting for the excess, the quantity of zinc is calculated from the amount of thiosulphate used.

The author finds that the addition of powdered lead and iron to the zinc makes very little difference in the quantity of zinc found by this process, the results being a little lower in the presence of these metals.

The results by this method agree well with those obtained by Fresenius' method, but are generally higher than those obtained by Drewson's and lower than those obtained by Töpfer's method.—A. G. B.

*Estimation of Zinc in its Ores.* D. Coda. *Zeits. Anal. Chem.* **29**, 266—271.

THE usual method of determining zinc in its ores consists in dissolving the ore in aqua regia, evaporating, redissolving in dilute hydrochloric acid, precipitating lead, copper, and cadmium with hydrogen sulphide, oxidising the iron and precipitating with ammonia containing some ammonium carbonate; the iron is thus precipitated and the zinc remaining in solution is estimated with standard sodium sulphide solution. The objection to this method is that the iron precipitate invariably contains zinc, even in the presence of ammonium carbonate and when the precipitate is left in the liquid for 24 hours. Better results are obtained by dissolving the precipitate and reprecipitating it, allowing it to remain in the liquid for 24 hours after reprecipitation; but this is not expeditious.

The new method which the author has devised depends upon the fact that if ammonium sulphate be present the ferric hydrate will combine with it instead of with the zinc oxide. The method is carried out as follows:—

2.5 grms. of the zinc ore are dissolved in 15–20 cc. of aqua regia and evaporated to dryness. 15–20 cc. of sulphuric acid are added and the mass heated till white fumes come off; it is then diluted, precipitated with hydrogen sulphide, and filtered; the hydrogen sulphide is expelled from the filtrate by heat and ammonia is added till the liquid is neutral; 40 cc. of ammonia containing 25 per cent. of ammonium carbonate are then added. After the flask has cooled its contents are made up to 500 cc. and filtered through a dry filter; 100 cc. (0.5 gm. of ore) are taken, diluted to 250 cc. and then titrated with a 2 per cent. solution of sodium sulphide. The details of the titration are as follows: A weighed quantity of pure zinc, as nearly as possible identical with the quantity in the ore, is dissolved in 4 cc. of concentrated hydrochloric acid, made alkaline with 20 cc. of ammonia, and diluted to 250 cc. This solution and that to be analysed are placed side by side and the sodium sulphide run in from a burette till the zinc sulphide is nearly all precipitated; the precipitate is then allowed to settle and a small portion of the clear liquid is placed on a porcelain plate and mixed with a spot of an 8 per cent. solution of sodium nitroprusside; this operation is repeated till a red colour is seen on mixing the drops; the flask must be well shaken after each addition of sodium sulphide.—A. G. B.

*Volumetric Estimation of Zinc according to E. Donath and G. Hattensaur.* L. Blum. *Zeits. Anal. Chem.* **29**, 271–272.

The author objects to Donath and Hattensaur's method for the titration of zinc in an "ammoniacal tartaric acid solution," with potassium ferrocyanide (this Journal, 1890, 554), on the ground that manganese when present will be precipitated under the conditions of the process (compare this Journal, 1887, 226); the results by this method are thus liable to be too high. Mahon (this Journal, 1882, 505) has also pointed out the disturbing influence of manganese when zinc is titrated with potassium ferrocyanide in hydrochloric acid solution.—A. G. B.

*Estimation of Metallic Aluminium in Commercial Aluminium.* G. Klemp. *Zeits. Anal. Chem.* **29**, 388–390.

The author treats a weighed quantity of the aluminium to be tested with a solution of potassium hydrate, and determines the quantity of hydrogen that is evolved either by measuring the volume of the gas or weighing the water produced by burning it. In the first case most of the ordinary gas analysis apparatus may be used, especially Lunge's improved apparatus (Ber. **23**, 440; this Journal, 1890, 547–549). In the second case the apparatus described by R. Fresenius for his zinc-dust estimation is suitable.

In testing the applicability of the method the author has used Fresenius' apparatus. He employs a solution of caustic potash that contains 35 grms. of KOH per 100 cc. The aluminium is disintegrated with a file and the filings weighed in a weighing tube, about 1 gm. of them then shaken into an Erlenmeyer's flask of about 150 cc. capacity, and the tube again weighed. The aluminium is covered with a little water, and some vaselin is added to prevent frothing. The hydrogen evolved by the caustic potash solution is burnt in a Fresenius' apparatus and collected in concentrated sulphuric acid. To prevent a too rapid evolution of hydrogen the caustic solution is added in small quantities. The aluminium takes about three-quarters of an hour to dissolve and, to expel the last portions of hydrogen, the liquid is warmed towards the end of the reaction.

A sample tested by this method gave 98.42 per cent. and 98.37 per cent. of Al; the same sample tested gravimetrically by precipitation with ammonia and ammonium chloride, and deducting the iron precipitated at the same time, gave 98.14 and 98.31 per cent. of Al.—H. S. P.

*Determination of Water in Superphosphates.* J. J. Stoklasa. *Zeits. Anal. Chem.* **29**, 390–397.

ALL methods heretofore proposed for the estimation of water in superphosphates give varying and incorrect results.

In this paper the author treats of the influence of temperature on mono-calcium orthophosphate. The experiments were made with a chemically pure preparation of the following composition:—

	Per Cent.
CaO .....	22.34
P <sub>2</sub> O <sub>5</sub> .....	56.67
H <sub>2</sub> O .....	21.53
Free phosphoric acid .....	0.014

On drying 3.590 grms. of this substance at 100° its weight became constant after 50 hours, and the loss of water was 6.43 per cent., which is equivalent to one molecule of water. At 100° therefore CaH<sub>4</sub>(PO<sub>3</sub>)<sub>2</sub>·H<sub>2</sub>O loses its water of crystallisation after 40 hours' heating. The calcium phosphate so obtained forms opaque and non-hygroscopic crystals of the composition 21.02 per cent. CaO, 60.74 per cent. P<sub>2</sub>O<sub>5</sub>, and 15.00 per cent. H<sub>2</sub>O. It is soluble without decomposition in water in the proportion of 1:200, but dissolves very slowly.

If this substance be heated to 105° it undergoes very slight alteration until after 20 hours' heating, and then only a small proportion decomposes, but by raising the temperature gradually to 200° the decomposition is accelerated, and takes place as follows:—

By treating the substance so obtained with water in the proportions of 1:200, at 15° C., the undecomposed mono-calcium phosphate, the mono-calcium pyrophosphate, and the phosphoric acid are dissolved out, leaving a residue of calcium pyrophosphate and metaphosphate.

Birnbaum (*Zeits. f. angew. Chem.* 1871, 137) discovered the formation of calcium pyrophosphate and free phosphoric acid, but says nothing of finding metaphosphate and mono-calcium pyrophosphate. His equation—

is impossible as calcium pyrophosphate and phosphoric acid when heated produce mono-calcium pyrophosphate.

Drewson (*Zeits. Anal. Chem.* **20**, 54), in writing of the changes in superphosphate at high temperatures, says nothing of the formation of normal pyrophosphate and metaphosphate, but he found even at 100° that a considerable amount of mono-calcium pyrophosphate was formed. Drewson's analyses also show that when heated even to 300° the amount of soluble phosphoric acid in the superphosphate remained unchanged, which for a superphosphate of ordinary composition is certainly a great anomaly. The author repeated the experiment with an ordinary superphosphate heated to 120° and found a considerable decrease of soluble phosphoric acid in the aqueous solution of the superphosphate after heating. But by supposing that Drewson used a superphosphate in which 80 per cent. of the soluble phosphoric acid existed as free H<sub>3</sub>PO<sub>4</sub>, the anomaly would be explained by the reaction between the pyrophosphate, formed by the heating, and the free phosphoric acid according to the equation—

soluble mono-calcium pyrophosphate being formed.

The author has tested the accuracy of this equation by heating 2 grms. of pure calcium pyrophosphate with 1.202 grms. of phosphoric acid in a platinum dish for 10 hours at 200° C. At the end of this time the aqueous solution only contained traces of free phosphoric acid. Before warming with nitric acid the solution contained mono-calcium pyrophosphate and 4 per cent. of phosphoric acid; after heating with nitric acid 56.08 per cent. of phosphoric acid was found, so that in this case first mono-calcium orthophosphate has been formed, and this has on

further heating lost water with formation of mono-calcium phosphate.

The author also finds that when mono-calcium phosphate is heated at 150° and higher, that not only the temperature but also the length of time it is heated influences the formation of mono-calcium pyrophosphate.

When mono-calcium phosphate was dried at 205° and extracted with water, the solution, after boiling with nitric acid, contained 16·2 per cent. of phosphoric acid, whilst before boiling with acid it only contained 2·3 per cent. The insoluble residue was all calcium metaphosphate. When  $\text{CaH}_2(\text{PO}_3)_2 \cdot \text{H}_2\text{O}$  was heated at 210° it lost 21·5 per cent. of water, and when treated with water left a residue of glassy calcium metaphosphate, insoluble in water, whilst only 0·86 per cent. of phosphoric was found in the aqueous solution. At this temperature, therefore, all the mono-calcium pyrophosphate formed immediately loses a molecule of water and becomes converted into calcium metaphosphate— $\text{CaH}_2\text{P}_2\text{O}_7 = \text{Ca}(\text{PO}_3)_2 + \text{H}_2\text{O}$ .

The influence of a temperature of 200° for one hour on mono-calcium phosphate is therefore expressed by the equation—

Further heating at 200° produces the following reaction:—

And further—

Finally at 210° the mono-calcium pyrophosphate is all converted into metaphosphate and water—

By heating the original mono-calcium phosphates from the commencement at 210° the whole reaction may be expressed by the equation—

*The Determination of the Hardness of Natural Waters by Soap Solution.* E. L. Neugebauer. Zeits. Anal. Chem. 29, 399—401.

To obviate the discrepancy found frequently in determining the hardness of water containing magnesia salts, between the hardness as shown by Clark's test and that indicated by the gravimetric analysis of the water, the author standardises his soap solutions against a mixture of 8 volumes of a 12° solution of calcium sulphate and 2 volumes of a 12° solution of magnesium sulphate, such a mixture representing an average hard water. He makes his soap solution of such a strength that 12 cc. of it produces a permanent froth in 100 cc. of this 12° mixture. The soap solution must be added slowly, in quantities of 1 cc. at first and towards the end drop by drop, and the operation is ended when a froth remains on the water for five minutes. Only 100 cc. of water are taken, and it is shaken up in a bottle of 200 cc. capacity. By diluting the 12° mixture of calcium and magnesium sulphates with distilled water, solutions can then be made of hardnesses of from 1°—12°, and the quantity of soap solutions corresponding to each degree of hardness can then be found by experiment. The author has had a burette made, graduated in degrees and tenths, corresponding to the various volumes of soap solution required by the solutions of various degrees of hardness from 1° to 12°.

In testing a natural water, the readings of such a burette will be more accurate the more diluted (within certain limits) is the normal volume of the water, and the nearer the relationship of the lime to the magnesia in the water to be tested, expressed in degrees of hardness, approaches that of 80 to 20.—H. S. P.

*The Detection of Natural Mineral Phosphates in Thomas' Phosphate Meal.* L. Blum. Zeits. Anal. Chem. 29, 408—411.

The considerable rise in price of Thomas' slag makes it worth while to adulterate it with certain classes of natural mineral phosphates as, for example, the Mons phosphates, containing 40—45 per cent. calcium phosphate, which is sold at a price equal to 0·11 franc per kilogramme of calcium phosphate. It would only pay to use such natural phosphates for adulteration as were unsuitable for making superphosphates, owing to the quantity of calcium carbonate they contain, as a sufficiently good price is given by superphosphate makers for all natural high-grade phosphates. Thomas' slag, when fresh, contains no carbonic acid, and the author only found 2·28 per cent. carbon dioxide in Thomas' slag that had been exposed in the open air for three years, and he finds that the maximum percentage of carbon dioxide in Thomas' slag examined by him is about 2·5 per cent. Such phosphate as the Mons phosphate (the grey phosphate chalk) contains about 22 per cent. of carbon dioxide.

The determination of the carbon dioxide in a sample of Thomas' meal therefore affords a test of its freedom from or adulteration with natural mineral phosphates, although it does not afford a very definite method of determining the amount of that adulteration.

It is only necessary to determine the loss by calcination to see whether it contains an undue proportion of carbon dioxide.—H. S. P.

*The Chemical Constitution of Tale.* F. W. Clarke and E. A. Schneider. Ber. 23, 1537—1540.

The sample of tale with which the experiments were carried out came from Hunter's Mill, Virginia, and when dried in air gave the following analysis:—

	Per Cent.
$\text{SiO}_2$ .....	62·27
$\text{Al}_2\text{O}_3$ .....	0·15
$\text{Fe}_2\text{O}_3$ .....	0·95
$\text{MgO}$ .....	30·95
$\text{FeO}$ .....	0·85
$\text{MnO}$ .....	Trace.
$\text{H}_2\text{O}$ (105°) .....	0·07
Loss in ignition .....	4·84
	<hr/> 100·08

These figures agree closely with the empirical formula  $\text{H}_2\text{Mg}_3\text{Si}_4\text{O}_{12}$ . Tale is usually held to be an acid metasilicate,  $\text{H}_2\text{Mg}_3(\text{SiO}_3)_4$ . Groth, however, prefers to consider it a basic pyrosilicate,  $\text{Mg}(\text{Si}_2\text{O}_5)_2(\text{MgOH})_2$ , derived from the acid  $\text{H}_2\text{Si}_2\text{O}_5$ .

Olivine behaves like tale to hydrochloric acid gas, being only superficially attacked, but tale is the only one of these minerals that withstands the action of aqueous hydrochloric acid.

This power of tale for resisting the action of hydrochloric acid is a strong argument against considering it to be a basic pyrosilicate.—F. H. L.

*On the Action of Sulphurous Acid on Metals.* J. Uhl. Ber. 23, 2151—2154.

SULPHUROUS acid acts upon palladium and platinum with evolution of sulphuric anhydride and formation of a sulphide. With gold no sulphide is obtained. Very little or no sulphuric anhydride is evolved with copper, silver, or cadmium, the residue consisting of a mixture of sulphide, sulphate, and other sulphur compounds. Magnesium burns in a current of sulphurous acid, the residue containing sulphate, sulphite, and sulphide of magnesium. Antimony yields a mixture of the trioxide and the trisulphide. Aluminium, zinc, nickel, and cobalt apparently react with sulphurous acid, whilst mercury and bismuth are not acted upon at all.

The author proves the presence of sulphides by the evolution of sulphuretted hydrogen which takes place when hydrogen is passed over the heated residues. Serious doubts are thus thrown on the accuracy of the usual analytical method for estimating copper as  $\text{Cu}_2\text{S}$  by igniting the sulphide in a current of hydrogen, and the author also proves that reduction to metallic copper takes place even after igniting for only a quarter of an hour.

The equations explaining the above reactions are:—

*The Oxidation of Metallic Sulphides by the Electric Current.* E. F. Smith. Ber. 23, 2276—2283.

TWELVE months ago, in a preliminary note (Ber. 22, 1019) the author stated that the sulphur in metallic sulphides was converted into sulphuric acid by the action of an electric current; that, for example, the whole of the sulphur of copper pyrites might be completely oxidised in 10 minutes by this method, and that at the same time the oxides of the heavy metals, such as iron, copper, &c., might be eliminated, so that a precipitate of barium sulphate could be obtained quite white and free from the impurities that usually are so readily carried down with it. Details of the method, and apparatus used, are given in the present paper. The apparatus consists of a nickel crucible, from 1½ to 2 inches high, and from 1½ to 1¾ inch in diameter, which is supported in a ring of stout copper wire attached to a screw fixed to the base of an ordinary filter stand. The arm of the stand carries another screw, in which a strong platinum wire is fastened, which ordinarily constitutes the anode, the crucible being made the cathode. The other parts of the apparatus are, a battery, a "resistance," consisting of a wooden frame on which about 150 metres of iron wire are stretched, for regulating the amount of current, a commutator for reversing the direction of the current, and a Kohlrausch's ammeter, which is inserted between the commutator and the crucible. The "resistance" and the commutator are essential parts of the apparatus, as different sulphides require different amounts of current, and in some cases it is necessary to reverse the current, because a considerable quantity of metal becomes deposited upon the crucible, thus enclosing particles of undecomposed material.

30—40 grms. of caustic potash (not soda) are heated in the crucible until the excess of water is expelled, the weighed quantity of the sample is added to it, the crucible is placed in the copper-wire support, and the platinum wire forming the other electrode is dipped into the melted mass. It is necessary to keep the crucible covered during the oxidation. The current is then closed, and in from 10—20 minutes the sulphur is usually perfectly oxidised. The current is then interrupted, the crucible cooled, and its contents treated with water, which dissolves all but the metallic oxide that has been formed. The liquid is filtered, acidulated, and the sulphuric acid precipitated in the usual way. Should the solution become turbid when acidulated, the oxidation has not been perfect. It should be noticed whether sulphur dioxide is evolved when acid is added, and the residue insoluble in water must always be tested for sulphur. If the potassium hydrate contain sulphur, of course a correction must be made on account of this.

The author then describes the oxidation of various sulphides. Zinc blende, cinnabar, galena, argentite ( $\text{Ag}_2\text{S}$ ), molybdenite ( $\text{MoS}_2$ ), antimony sulphide, orpiment ( $\text{As}_2\text{S}_3$ ), jamesonite ( $\text{Sb}_2\text{S}_3\text{Pb}_2$ ), enargite ( $\text{AsS}_2\text{Cu}_3$ ), stephanite ( $\text{Sb}_2\text{S}_3\text{Ag}_{10}$ ), kobellite ( $\text{BiSb}_2\text{S}_3\text{Pb}_2$ ), tin pyrites ( $\text{SnS}_2\text{Cu}_2\text{Fe}$ ), and fahl ore were all satisfactorily oxidised, the current varying, according to the substance operated on, from 1 to 2 amperes, and the time required for oxidation from 10—20 minutes. Copper glance (redruthite,  $\text{Cu}_2\text{S}$ ) resisted all attempts to completely oxidise the sulphur, repeated reversals of a very large current only resulting in the oxidation of about half the sulphur.

The sulphides of iron act in an interesting manner. Magnetic pyrites (pyrrhotin,  $\text{Fe}_{11}\text{S}_{12}$ ) was easily oxidised.

Similarly, white pyrites (marcasite,  $\text{FeS}_2$ ) suffered complete oxidation. On the other hand, yellow pyrites (mundie,  $\text{FeS}_2$ ), though of the same chemical composition as marcasite, was most difficult to oxidise, one atom of sulphur persistently remaining unoxidised. By mixing an equal weight of cupric oxide with the pyrites, and using a current of 4 amperes, fairly satisfactory results were obtained. The use of cupric oxide was suggested by the facility with which copper pyrites could be oxidised by this method. The different behaviour of marcasite and mundie leads to the assumption that their chemical constitution is dissimilar.—H. S. P.

*An Azotometer for the Estimation of Nitrogen in Ammonium Salts.* W. Hentschel. Ber. 23, 2402—2403.

THE apparatus somewhat resembles V. Meyer's vapour density apparatus. The chief part is a cylindrical tube A, widened at the upper part, where a double-bored cork closes it, and surrounded by an outer tube, in which vapour can be

AN AZOTOMETER.

generated for heating the contents of A. The lower part of A holds a solution of sodium hypobromite. Through one hole in the cork passes the tube B, which on the outside is connected with a bent tube leading to a graduated measuring tube, whilst on the inside it is bent into a hook shape. Upon this hook is hung by a platinum wire the bucket C, which contains the solution of the ammonium salt. This "drop cylinder" or bucket is weighted with a sealed bulb containing mercury. Through the second hole in the cork passes a glass rod bent at right angles, by means of which the drop cylinder can be slipped off the hook and thus allowed to fall into the hypobromite solution below. In his experiments the author used methyl alcohol in the outer heating tube; after boiling for 15 minutes a constant temperature was obtained. When the bucket is allowed to drop the solutions of ammonium salt and hypobromite quickly mix, and in a few minutes all the nitrogen is liberated in the form of small bubbles, whilst at the same time a corresponding volume of air and nitrogen enters the measuring tube. The author has demonstrated by experiment that no correction is necessary unless extreme accuracy is aimed at, probably owing to the warm hypobromite solution having a smaller absorbing capacity than the cold solution usually used in other azotometers.—H. S. P.

*Schulze-Tiemann's Method for determining Nitric Acid in Water.* E. Schmidt. Apoth. Zeit. 1890, 287.

ACCORDING to the quantity of nitric acid present, 50—500 cc. of water are evaporated to 20—30 cc., and these are drawn up into flask A. Before connecting with the collecting

THE ESTIMATION OF NITRIC ACID.

apparatus B, the latter is first filled up to *i* with mercury, and the vessel *g* attached to *h* by a piece of india rubber tubing. Schiff's collecting apparatus may now be filled with caustic soda (20—30 per cent.), which must be boiled previous to the experiment, and introduced warm. Sufficient caustic soda should be used to fill part of *g* when the latter is raised a little over the level of stop-cock *h*; *h* is then closed and *g* fixed at the same level as the stop-cock. The pinch-cock *b* being closed and *e* opened, the water in A is brought to a boil. The air bubbles which now rise in B are allowed to escape by opening *h* and raising *g*. When no more air collects in B, *c* is closed and *b* opened. The steam issuing from *a* is passed into a mixture of equal parts of a saturated and freshly prepared solution of ferrous chloride and fuming hydrochloric acid, in order to expel any air. When only 5 cc. of water are left in the flask, *b* also is closed and the flame at once removed.

By opening *b* after some time, about 10 cc. of the ferrous chloride mixture are allowed to enter the flask. *b* is again closed and heat applied until pressure is noticeable by the rubber tubing at *e* becoming inflated. The stop-cock *e* is then opened, the contents of the flask evaporated to dryness, and *e* is again closed. As soon as a negative pressure is observed in A a further 5 cc. of the ferrous chloride mixture are introduced and the operations carried out as above. On now evaporating to dryness all nitric oxide will have collected in B, and the volume may be read off after adjusting the level of the liquid in *g* to that in B. (See also this Journal, 1890, 896—897.)—A. R.

*The Chemical Society of Aachen.* Meeting of June 12th, 1890. Chem. Zeit. 14, 855—856.

CLASSEN has been able to detect traces of lead in bismuth preparations which appeared to be free from lead by a spectroscopic examination. The substance is converted into nitrate and electrolysed in the presence of an excess of nitric acid; lead peroxide and bismuth peroxide separate out, but the greater portion of the latter dissolves. The peroxide is converted into nitrate and saturated with pure soda solution, potassium bichromate is added to the pure solution, which precipitates bismuth chromate, whilst the lead remains in solution and may be precipitated from the filtrate by acidifying with acetic acid.

Vortman described a new volumetric method for estimating copper. If sodium thiosulphate be added to a solution of a copper salt, a double salt,  $\text{Cu}_2\text{S}_2\text{O}_3 \cdot \text{Na}_2\text{S}_2\text{O}_4$  is formed which is decomposed on boiling.

If as much sulphuric acid be previously added as is sufficient to just decompose the added thiosulphate, then at the conclusion of the reaction there remains an amount of free sulphuric acid corresponding to the amount of copper taken and it may be determined according to some acidimetric process.

The titration is carried out as follows; the copper solution (preferably sulphate) must first be neutralised, this may be done by adding an excess of hydrogen peroxide and then potassium permanganate until a brown precipitate appears, when the solution will be just neutral, the following reaction having taken place:—

the reaction proceeds best at 70°—80° C. An excess of decinormal sodium thiosulphate is added to the neutralised solution and as much decinormal sulphuric acid as is necessary to just decompose the thiosulphate. The solution is boiled until completely decomposed, an excess of potassium iodide and iodate added to the solution, titrated back with decinormal thiosulphate; 4 l is equivalent to 2 Cu. The results are very satisfactory.

*Ferrous salts* may be estimated by oxidation with iodine by adding sodium acetate and acetic acid and then a measured excess of iodine solution, and after standing 15 minutes, titrating the excess of iodine.

*Nitric acid* may be estimated by electrolysis in the presence of copper sulphate, when it is completely converted into ammonia. The titrate is dissolved in a platinum dish, sulphuric acid and copper sulphate added and the solution electrolysed in the usual way; it is then distilled with soda and the ammonia which is evolved estimated in the usual manner. If the nitric acid is already in combination with a metal which is deposited on electrolysis, the copper may be omitted.

*Aluminium* in solutions containing phosphoric acid, such as occur when iron is electrolytically deposited from a solution of ferro-aluminium, may be easily separated from such metals as manganese, &c. in the following way. The solution is neutralised with soda and an excess of sodium acetate, phosphate and acetic acid added whereby all alumina is precipitated as phosphate; this is washed with dilute ammonium nitrate, ignited and weighed as  $\text{AlPO}_4$ .

*Cobalt* in ammoniacal solution is oxidised by alkaline hypochlorites whilst nickel is not. To take advantage of this for the separation of cobalt and nickel, an excess of ammonia is added to the solution and a slight excess of alkaline hypochlorite and the whole warmed until the excess of ammonia is destroyed. Potash is added to this when  $\text{Co}_2\text{H}_6\text{O}_6$  and  $\text{NiH}_2\text{O}_2$  are precipitated. The precipitate is washed and transferred to a beaker; potassium iodide and hydrochloric acid added;  $\text{Co}_2$  liberates  $\text{I}_2$  which is titrated with thiosulphate.—A. L. S.

*Estimation of the Zinc as Carbonate and Silicate in Calamine containing Lead.* W. Minor. Chem. Zeit. 14, 1003.

THIS is a modification of the author's method for the determination of the zinc existing as carbonate and silicate in calamine ores containing lead (Chem. Zeit. 13, 1670; this Journal, 1890, 417). Two grms. of calamine are boiled

with 50 to 60 cc. of dilute caustic soda solution for about 15 minutes, the insoluble matter is allowed to settle, the liquid filtered, and the residue again boiled with soda as before. The second liquid is also filtered, and the residue washed on the filter with hot dilute soda. The filtrates are added together, acidulated with sulphuric acid to remove the lead, made up to a known bulk, and, after standing several hours, half of the liquid is filtered. This solution is then made alkaline with ammonia and the zinc estimated by titration with sodium sulphide. Since the greater part of the zinc existing as sulphide in calamine ores is lost during the smelting, a method for determining that combined with carbonic and silicic acids only is of great importance. It is not necessary after adding the ammonia to filter off any alumina that might be precipitated.—A. W.

*A New Method for the Estimation of Nitrates and Nitrites in Water.* R. Ormandy and J. B. Cohen. J. Chem. Soc. (Trans.) 1890, 811—815.

THE process resembles that of Gladstone and Tribe. The zinc-copper couple is replaced by thin sheet aluminium coated with a film of metallic mercury. This is effected by shaking the foil with a solution of mercuric chloride (1 vol. of a saturated solution with 1 vol. of water). Metallic mercury adheres to the surface of the aluminium and the couple, after being washed a few times with pure water, may be introduced into the water to be analysed. The aluminium-mercury couple acts more rapidly than the zinc and copper and gives equally good results. Nitrates in small quantities such as occur in natural waters are entirely reduced by the couple in about an hour. The couple is left in contact with the measured quantity of water in the cold until the aluminium is converted into oxide. Water and precipitate are then transferred to the retort for distillation. The nitrate is converted into ammonia, the amount of which is estimated by Nessler's reagent in the usual way.

Before preparing the couple the aluminium foil must be heated in a current of hydrogen or in a Bunsen flame to remove any grease that may be present.

It is well known that albuminoid substances undergoing decomposition split up into simpler organic nitrogen compounds before free ammonia makes its appearance. The authors determined whether the zinc-copper or aluminium-mercury couple effected any change by hastening decomposition when in contact with the partially decomposed albumin. The following is the summary of the results:—

1. Neither couple affects the amount of free ammonia produced during the decomposition of the albumin, that is to say, the amount of free ammonia given off each day by the decomposing albumin was the same with or without the addition of the couple.

2. The addition of caustic soda to the albumin solution and to the solution with the zinc-copper couple set free an additional quantity of ammonia, which was the same in the two cases.

3. In the case of the albumin solution, acted upon by the aluminium-mercury couple, the amount of free ammonia produced by the addition of caustic soda was largely in excess of that in the other two solutions. It is evident that the aluminium couple acts upon the products of the decomposition of the albumin, which are decomposed only on the addition of caustic soda.—J. B. C.

*Determination of Manganese and Zinc as Pyrophosphates.* R. C. Boyd. School of Mines Quarterly, 11, 355—358.

In the precipitation of manganese as double phosphate by microcosmic salt, it has hitherto been considered necessary to work with absolutely no excess of ammonia. Slight excess of ammonia is, however, shown by the author not to be detrimental. Furthermore it has been deemed advisable to filter ice-cold. This, too, is shown to be unnecessary, as also is washing with a 10 per cent. solution of ammonium nitrate. Hence precipitation and filtration are both performed hot, and only about 50 cc. of washings become

necessary to remove the sodium salt and excess of alkaline phosphate. After ignition with the usual precautions, the precipitate becomes manganese pyrophosphate,  $Mn_2P_2O_7$ .

With regard to determination of zinc by this method, the precipitation is made as follows:—An excess of microcosmic salt is added, and the whole is heated to boiling, and then a slight excess of ammonia added. The boiling is continued until no smell of ammonia is noticeable. The precipitate is then filtered and washed by decantation, as much of the precipitate as possible being kept in the beaker. When the washings give no reaction for phosphates, the precipitate is dissolved in the beaker by the aid of a little nitric acid, and the solution is poured through the filter into a weighed platinum dish, and the zinc compound rinsed into the same with a little distilled water. After evaporating and carefully igniting, the dish and contents are weighed. By this means the reducing action of burning filter paper upon the precipitate is avoided. While cooling, the dish should be covered, as sometimes the residue "snaps," and portions may be projected from the dish unless this be covered. Analyses show very good results in the case of both manganese and zinc.—T. L. B.

ORGANIC CHEMISTRY.—QUALITATIVE.

*Adulteration of Commercial Olein with Linoleic Acid.* Grandval and Valser. Bull. Soc. d'Encour. Ind. Nat. 1890, 404—407.

SO-CALLED "olein," in reality crude oleic acid, is a by-product of candle-making, being separated from the more valuable stearic acid by pressing at carefully regulated temperatures, and is chiefly used for soap-making and as a lubricant for wool-spinning. For the latter purpose, some manufacturers prefer it to olive oil, because it is cheaper and easier to remove from the fibre, sodium carbonate serving as a detergent instead of soap, which is necessary when oil is used.

Recently goods for which oleic acid has been used have been damaged by the appearance on them of yellow stripes, which persist, even after washing and bleaching, and are fatal to the successful dyeing of delicate tints. The authors attribute this state of things to the presence of linoleic acid, and account for it in the following way:—

The growing trade in margarine has led to the practice of pressing fresh fats of animal origin for the sake of their olein, which is used in its manufacture. The process, whether carried out by candle-makers themselves or pursued as a separate industry, yields a mass of stearin so hard that it is troublesome to deal with after saponification for the preparation of stearic acid. Accordingly the requisite consistency for successful pressing is obtained by adding the fatty acids resulting from the partial saponification of linseed oil, which is chosen both because of the fluidity of the greater part of its fatty acids, and because it contains a certain proportion of solid fatty acids which augments the yield obtained. The "olein" got by pressing such a mixture of course contains drying fatty acids, of which linoleic acid is a type. When used for greasing wool, no ill-effects are noticed if the material be woven and washed soon afterwards, but if stored some weeks before weaving exposed to light and air, discolouration takes place, and is only hidden by dyeing with dark colours. Besides this defect, a good deal of waste is produced, and the fibre is harsh, sticky, and rather more troublesome to get free from grease; no other inconvenience, however, appears to result.

The detection of such adulterated oleic acid is tolerably simple, and is best effected by direct comparison with genuine oleic acid. The sophisticated variety is of paler tint than the genuine, and has a specific gravity of 0.912—0.919 at 15° C., instead of 0.905. It often contains a good deal of solid matter, and the specific gravity is best taken at a somewhat higher temperature, and corrected by use of the constant 0.00064 for each degree centigrade. On heating repeatedly to about 50° C. and cooling, the spurious grease becomes more and more buttery, while the consistency of the genuine is unaffected. When 50 grms. are shaken with

450 cc. of alcohol at 85 per cent., a shining deposit is formed; oleic acid thus treated dissolves completely. A residue is also given by any mineral rosin or fatty oil that may be present, but is easily distinguished from it by its different appearance. Definite proof of the nature of the deposit may be had by collecting it on a filter, washing with alcohol and drying, when it will be found to fuse at about  $47^{\circ}\text{C}$ ., and to dissolve easily in boiling alcohol, being deposited therefrom on cooling. It saponifies readily and completely, yielding a soap whose solutions gelatinise in the cold even when very dilute.

The recognition of drying fatty acids may also be effected by the elaidin reaction. Other tests are based on the greater tendency to dry when exposed on a clean leaden surface and the yellow colour given by shaking with an equal volume of caustic soda, pure oleic acid giving only a grey tint.

Judged by such means, adulterated samples of "olein" can be condemned and damage avoided.—B. B.

*A New Method for Detecting Colouring Matters added Fraudulently to Wine.* J. Weirich. Monit. Scient. 1890, 4, 689—699.

A SMALL quantity of the wine to be tested is brushed on a piece of paper which should not be absorbent, allowed to dry, exposed to the light, and examined from time to time, the tint communicated to the paper by a natural wine is of totally different character from that due to an artificially coloured wine. The natural colouring matters of wines and other vegetable colouring matters change each in a definite way on the paper; mineral colouring matters do not alter. Experiments should be made with natural and artificially coloured wine of different vineyards, when the working of the test will be soon understood.—A. L. S.

*Reaction of some Phenols in the Presence of Chloroform and Alkali.* Monit. Scient. 1890, 4, 710—713.

THE phenols give with chloroform and alkali a characteristic colour reaction, and this is recommended as a general reaction for identifying these compounds. To perform the test, the phenol is dissolved in chloroform, a small piece of potash added and the solution boiled. The characteristic colouration is quickly developed. Reducing and oxidising agents affect the reaction, alcohol sometimes accelerates and sometimes hinders it, ether nearly always impedes it, with aqueous solution the reaction is less sharp; in this case it is best to shake up with chloroform and proceed with the decanted chloroform as usual, or to extract with ether, boil the ether off and dissolve the residue in chloroform.

*Phenol.*—A pale red colouration is first produced which becomes brown, then yellow, and finally colourless. The reaction is sensitive with 1 part to 60,000 chloroform.

*o-Cresol.*—Lilac colouration with an orange shade. Sensitive with 1 part in 80,000.

*m-Cresol.*—As *o*-cresol but a more marked orange shade. Same sensitiveness.

*Thymol.*—Fine red colouration verging on purple with a violet tinge, which is accentuated by the addition of a little alcohol or ether, and soon disappears. Sensitive to 1 part in 20,000.

*Guaiacol.*—Cherry red colouration with a blue tinge, changing to violet-blue. Sensitive to 1 part in 100,000.

*Resorcinol.*—On warming gently, a cherry red deposit on the potash and a brownish yellow colouration of the chloroform; the chloroform ultimately takes up the colour, which is fairly stable. Sensitive to 1 part in 500,000.

*Quinol.*—Bluish-green colouration soon disappearing. Sensitive to 1 in 20,000.

*Pyrogallol.*—A reddish-brown colouration in the cold, which on warming takes on a green tinge, and on boiling soon disappears. Sensitive to 1 in 300,000.

*$\beta$ -Naphthol.*—Prussian blue colouration, changing to green and then brown. Sensitive to 1 in 80,000.

*Salol.*—Red colouration like phenol.

*Betol.*—Bluish-green colouration like  $\beta$ -naphthol.

With these last two it is best to boil with a little potash before adding the chloroform in order to saponify the ether. The colours then obtained are very characteristic.

When testing for phenols in complex liquids such as blood, the contents of a stomach, &c., it is best to acidulate and distil in a current of steam. The distillate may be examined as above.—A. L. S.

*On the Detection of Fish Oil in Linseed Oil.* A. Ruffin. Chem. Zeit. Rep. 14, 205.

THE original statement made in 1839 by Fauré, that linseed oil containing fish oil is coloured black by chlorine requires modification. By passing chlorine into pure linseed oil and excluding the air, a green colour appears after a few minutes. On now leaving in an open vessel the colour gradually turns brown and in 24 hours perfectly black. In a closed vessel this change takes place less rapidly. If the current of chlorine be stopped when the oil becomes green, the oil turns black much faster. When the action of chlorine is allowed to take place in an open vessel, after a few minutes a momentary green colouration is observed, rapidly changing to black. With mixtures of linseed and fish oil in the most varying proportions a green colouration is never observed, but previous to the oil turning black a characteristic brown colour appears. In examining linseed oil it is therefore necessary to take into account whether the oil is old or fresh, and whether the sample has been taken from closed or open, full or partly empty vessels.—A. R.

*On Orexine.* A. Donner. Pharm. Zeit. 1890, 418.

OREXINE, the hydrochloride of phenyldihydroquinazoline, is used as a stomachic (see this Journal, 1890, 887). Its formula is  $\text{C}_{11}\text{H}_{12}\text{N}_2\text{HCl} + 2\text{H}_2\text{O}$ , and it crystallises in needles which melt at  $80^{\circ}$ , the anhydrous substance melting at  $221^{\circ}$ . The water of crystallisation is given off by mere exposure to the air. It is readily soluble in water and alcohol. In the aqueous solution (1:20) mercuric chloride produces a white, potassium bichromate a yellow precipitate. Potassium permanganate is decolourised in the cold already. A characteristic reaction is to heat orexine with zinc powder over the direct flame, when a strong smell of isonitrile becomes apparent. On now treating the mixture with hydrochloric acid and adding chloride of lime to the filtrate the solution is coloured blue.—A. R.

ORGANIC CHEMISTRY.—QUANTITATIVE.

*Combustions under High Pressure.* W. Hempel. Ber. 23, 1455—1460.

It is well known that during the combustion of sulphur considerable quantities of sulphuric anhydride are produced, and that during the burning of hydrogen, coal-gas, or coal, traces of nitrous acid are formed. The following experiments shown that under pressure larger quantities of these substances are produced.

1. Sulphur burnt in a mixture of air and oxygen in excess.

No. of Experiment.	Pressure.	Sulphur Burnt.	SO <sub>2</sub>	SO <sub>3</sub>
			Per Cent.	Per Cent.
1	Atmospheric....	*5375	98*0	2*0*
2	31*0 atmospheres.	*238	66*8	32*2
3	41*5     "     "	*268	34*7	65*3*
4	72*5     "     "	*336	54*5	45*5*
5	75*5     "     "	*328	59*8*	26*4

\* Estimated.

In the last experiment a considerable amount of the sulphuric anhydride volatilised during the evaporation of the sulphurous oxide.

II. Varying mixtures of air, oxygen, and the mixture of hydrogen and oxygen formed by the electrolytic decomposition of water, compressed in a steel vessel holding about 28 cc. filled with chips of platinum moistened with concentrated potassium hydrate. The resulting nitric acid estimated as nitric oxide by Schulz's method.

No. of Experiment.	Pressure in Atmospheres.			cc. of NO.
	Air.	Oxygen.	H <sub>2</sub> +O.	
6	2.5	12.8	38.5	2.8
7	1.0	18.3	43.5	4.8
8	1.0	27.0	57.0	6.4
9	1.0	54.0	114.0	8.0
10	1.0	55.0	173.0	9.0
11	1.0	55.0	211.5	10.0

III. Combustion of nitrogen in presence of carbon and a large excess of oxygen. Potassium hydrate was employed as in series II. for the absorption of the nitric acid, and for the carbon a bituminous coal containing 2.8 per cent. nitrogen was used. The vessel, a steel autoclave, was filled with air at the ordinary pressure, the oxygen being afterwards pumped in till the necessary pressure was attained.

No. of Experiment.	Weight of Coal Burnt.	Pressure in Atmospheres.		cc. of NO.
		Air.	Oxygen.	
	Grms.			
12	.622	1.0	10.5	3.0
13	.576	1.0	33.8	3.0
14	.599	1.0	60.0	8.5
15	.793	1.0	73.0	9.0
16	.616	1.0	81.0	7.6
17	.622	24.0	92.0	14.0
18	.595	13.0	92.0	20.5
19	.711	92.0	217.5	5.0
20	.683	1.0	242.0	8.0
21	.632	12.5	88.0	25.0

In experiment 21 the .632 gm. of carbon consisted of a mixture of 25 per cent. of the coal previously employed and 75 per cent. of coke from chemically pure sugar.

Experiments 12—20 leave it doubtful whether the nitric acid was formed from the nitrogen in the coal, but No. 21 shows this not to have been the case, the sugar-coke containing no nitrogen.

The experiments also show that the proportion the different gases bear to one another and to the amount of coal burnt exerts a great influence on the amount of nitric acid produced.—F. H. L.

#### *The Examination and Valuation of Spirits.* W. Fresenius. Zeits. Anal. Chem. 29, 283—317.

THE author has analysed various samples of brandy, rum, arrac, and cherry-brandy, all of which were of ascertained genuineness. The results are given in the subjoined table.

The brandy samples 2 and 3 are very fine old brands, having been some 15 years in wood and originally containing some 61 per cent. of alcohol by volume. Samples 1, 4, and 5 are somewhat younger and originally weaker; they are,

however, of good quality. Samples 6 and 7 are much younger and either originally contained less alcohol or were reduced with water to be more quickly saleable. Sample 8 is slightly coloured with caramel.

One of the rum and of the arrac samples had one-sixth pure spirits of wine added to it, as the author believes this to be customary at times in the trade. The specific gravity was determined by the pycnometer and the alcohol found by Fehner's tables. In the rum and brandy samples the alcohol was also determined by distillation. The extract was determined by drying 50 cc. for 2½ hours in a water-oven, and from this the mineral matter by ignition. The free acid was determined by titrating 50 cc. with one-tenth normal alkali.

To determine Fehling-reducing substances the sample was so concentrated or diluted as to contain 1 per cent. of extract; the reducing power was then determined by Allihn's method, directly in one half, and after inversion in the other half; the difference before and after inversion was regarded as cane sugar. The results were calculated into invert sugar by Meissl's tables. The author remarks that if the reduction value is over 0.5 per cent. and increases considerably after inversion, the sample may be regarded as sugared. He allows a reduction value of about 0.2 per cent. for substances that are not sugar, and is of opinion that unsweetened brandies can contain more than 0.5 per cent. extract.

The determinations of fusel oil were made by Rose's method, the improvements of Stutzer and Reitnair being adopted (Zeits. Anal. Chem. 26, 376, 377; this Journal, 1886, 498).

The author has made many determinations of fusel oil, besides those quoted under the head "Chloroform-increase" in the table, both on samples of brandy, &c., and of commercial and pure alcohol. For Rose's method a large shaking apparatus was employed and 250 cc. of the alcohol and 50 cc. of chloroform were used. The spirit was distilled over potash solution and the distillate brought to 30 per cent. by volume (sp. gr. 0.9656), though it was found that a slight variation in the strength made a very little difference in the chloroform-increase. When different samples of chloroform were used the results on the same spirit differed slightly, so that for comparison the same chloroform was used for all the samples of spirit.

Several determinations were also made with Traube's capillarmeter and stalagmometer, but the reading of these instruments requires a great deal of practice.

On a previous occasion (Zeits. Anal. Chem. 26, 381) the author has asserted that even undoubtedly pure brandies give a higher chloroform-increase than pure alcohol and would consequently be reported as containing fusel oil; this he attributed to the probable presence of some higher alcohols which act similarly to fusel oil, or to added flavouring matters. This conclusion is not entirely confirmed by the present research, for it is seen by the figures in Table II. in the original paper that some of the pure brandies give the same chloroform-increase as Kahlbaum's pure alcohol. On the other hand some artificial brandies which almost certainly contain fusel oil show very little, and sometimes no, chloroform-increase; but it is quite possible that this may be due to the presence of some substance having an effect on the chloroform counter to that of the fusel oil. The author concludes that the results of testing for fusel oil are at present very uncertain and that the subject requires further investigation.

Testing for caramel was carried out according to Anstoth's directions (this Journal, 1885, 361). An expert, judging the brandies from their colour, pronounced 1, 6, and 7 as free from caramel, 2 and 3 as coloured by age, 4 and 5 as containing a little caramel, and 8 as undoubtedly coloured.

The author then proceeds to discuss the characteristics of pure brandy, and how such should be defined. The German Pharmacopœia pronounces brandy to be a product of the distillation of wine; a clear yellow fluid of peculiar spirituous smell and taste; it must be free from fusel oil and not sour; its specific gravity must be 0.920—0.924, and its alcohol contents 46—50 per cent. by weight. This definition, however, will exclude some of the finest and most undoubtedly genuine

brandies as containing too little alcohol (compare Elser, this Journal, 1888, 637).

Undoubtedly the best method of discerning a genuine spirit is by its smell and taste when such is practised by an expert. But in view of Custom house disputes it frequently falls to the lot of the chemist to pronounce upon the genuineness of a spirit and it is to be regretted that his means of doing so are so few and uncertain.—A. G. B.

See under XVII., page 959.

*Detection and Determination of Starch.* A. Leclere. J. Pharm. Chim. 1890, 641.

A CONCENTRATED solution of zinc chloride (sp. gr. 1.43—1.45) will dissolve starch and sugar, but not cellulose, fat, or nitrogenous substances. In this manner the starch may be separated from the fodder. 2 grms. in the case of cereals, or 5 grms. in the case of straw, hay, &c., are well powdered, and thoroughly moistened with 10 cc. of water. 180 cc. of the neutral zinc chloride solution being added, the flask is heated in a salt-bath at 108° until the cereal has dissolved; or, in the case of straw, &c. heating should at all events be continued for 1½ hours. After cooling, the solution is made up to 250 cc. with some zinc chloride solution. Where fibrous substances are under examination, the solution is made up to 253° to allow for the extra volume of the former. The solution is now filtered, which takes a considerable time, and 25 cc. of the filtrate mixed with 2 cc. of hydrochloric acid and 75 cc. of alcohol of 90 per cent. Starch and dextrin are thus precipitated, sugar remaining in solution. It is best to decant, after 24 hours' standing, through a tared filter. For washing the precipitate, alcohol of 90 per cent. is used to 1,000 cc., of which 5 cc. hydrochloric acid have been added. Finally alcohol only is used. The starch occasionally has an admixture of mineral substances the quantity of which may be determined by igniting; 25 cc. of the zinc solution gives a precipitate in the case of maize, weighing about 140 mgrms., of which 5 mgrms. are inorganic.

The starch obtained from cereals by the above means contains traces of nitrogenous substances which must be taken into account after a nitrogen determination. Thus in the above example with maize, the precipitate will contain 1.5—2.0 mgrms. of nitrogenous substances. With oats, the proportion of the latter is somewhat greater, with straw it may be neglected.—A. B.

*Determination of the Value of Dye-wood Extracts.* L. Schreiner. Chem. Zeit. 14, 961—962.

In judging of the value of dye-wood extracts, the following chief points should be observed:—(1.) The percentage of dyestuff. (2.) Addition of foreign dyes or substances containing tannic acids. (3.) Addition of weighting substances. (4.) Fermentation and reaction.

Like tannic acids, several dyes, such as hæmatoxylin and hæmatestin are entirely absorbed from their solution by powdered skin. This is a good means of separating the dyes from the other substances in the extract, more especially from adulterations such as sugar, molasses, and salts. The only disadvantage of this method is that tannic acid and the dyes cannot be determined separately. The author considers that this is not of great importance, seeing that where such dye-wood extracts containing tannin are used, the tannin cannot generally be regarded as of less value than the dye itself.

For an analysis 50 grms. of ground dye-wood are thoroughly extracted, the solution is diluted to 1 litre, filtered, and a portion of it allowed to percolate through skin powder, which must be pure and of a woolly nature. The filtrate should be perfectly colourless and remain so after

adding ammonia. 100 cc. of this filtrate and 100 cc. of the original extract are now evaporated separately, dried at 100° in the air-bath, and the difference gives the percentage of the dye.

When the extract itself is under examination, a solution which contains about 10 grms. dry substance per litre is best prepared. This is heated on the water-bath to 50° C., filtered if necessary with addition of kaolin and the clear solution examined as above. Moreover 1—2 grms. of the extract are dried in a platinum dish at 100° for determining the quantity of water, and then ignited in order to obtain the weight of the mineral constituents.

The difference between the dry substance and the sum of the dyes and non-dyes gives the amount of insoluble substances. The quantity of inorganic constituents is subtracted from the non-dyes in the subjoined table, the figures giving the percentage:—

FRESH LOGWOOD.

—	I.	II.	III.	IV. (Fresh.)	V. after Fermenting.
Dyes .....	12.06	10.56	8.16	9.70	9.23
Non-dyes .....	2.22	1.72	1.04	2.05	1.10
Water .....	10.86	12.80	10.8	10.02	16.00

LIQUID EXTRACT, 30° B.

—	I.	II.	III.	IV. (Solid.)	V.
Dyes .....	52.52	41.39	33.52	79.77	54.36
Non-dyes .....	6.06	11.91	14.59	9.08	18.14
Portion insoluble at 50° .....	0.45	2.87	6.99	1.05	9.20
Ash .....	0.14	1.81	3.47	0.22	6.04
Water .....	40.83	42.04	41.63	9.88	12.26

The advantage of an analysis is apparent when it is added that samples I.—III. had been valued as equal.

The quantity of non-dyes is of importance in wool-dyeing chiefly, as on this depends the degree of fermentation. The more thorough the latter the more perfectly is the dye contained in the wood eliminated from the latter. With regard to the analyses of the extracts, Nos. I. and IV. are normal extracts of good logwood. No. II. contains about 20 per cent., No. III. about 10 per cent. of a syrup containing considerable quantities of lime, and in No. V. molasses and sodium sulphate have been added. The reaction of a logwood extract may be judged by the colour of its solution. When neutral it is a deep red, an alkaline solution is bluish-red, and an acid one if not fermented light yellow, otherwise orange-yellow. Extracts to which tannic acids have been added always show an acid reaction, and in distinction to the naturally acid extracts, the colour does not at once turn into the neutral red on diluting with lime water or by shaking and warming with a little calcium carbonate.

Another characteristic reaction is to mix a solution of the extract (5° B.) with some stannic chloride, avoiding excess of the latter. A dark brown precipitate is formed if the extract has fermented, if not it is coloured a light violet, while in presence of tannic acids a dirty yellow precipitate is obtained.

Another good test for tannic acids is to add to a solution of 5 grms. of dry extract in 1 litre of water one-third its volume of yellow ammonium sulphide. If the extract be pure, a slight dark flocculent precipitate will be deposited, if tannic acids be present the solution will be decolourised and a heavy light grey substance precipitated.—A. R.

*Determination of the Value of Strychnos Seeds.* B. Holst and H. Beckurts. *Arch. Pharm.* 1890, 330.

For determining the quantity of alkaloids contained in strychnos seeds, 10 grms. are powdered and extracted with 75 parts of chloroform and 25 parts of alcohol containing a little ammonia. After distilling off the chloroform and alcohol from the extract the residue is dissolved in 10 cc. of a 5 per cent. solution of ammonia and 5 cc. alcohol, and shaken in a separating-funnel with chloroform 20, 10, and 10 cc. respectively. The latter is then distilled off, the residue heated on the water-bath until all ammonia has disappeared, then gently heated with 15 cc. of decinormal hydrochloric acid for 5 minutes, filtered, and washed. The excess of acid is now titrated back with centinormal caustic soda, using cochineal as indicator. By subtracting the cc. of centinormal caustic soda used from 150, the difference gives the number of cc. of centinormal hydrochloric acid necessary to neutralise the alkaloids. 1 cc. of centinormal hydrochloric acid corresponds to 0.0364 grm. of alkaloid, on the assumption that equal parts of strychnine and brucine are present.—A. R.

*On the Estimation of Raffinose and Invert Sugar in the Products of the German Beet Sugar Manufacturers.* *Chem. Zeit.* 14, 854—855.

THE Society of German Beet Sugar Manufacturers appointed a committee of experts to inquire into the methods of determining invert sugar and raffinose in beet-sugar syrups. The committee recommend that all analyses should be made in one definite agreed-upon manner, and submit the following details:—

*Polarisation.*—(a.) Whether the sample is warm or not is immaterial. (b.) It is not easy to dispense with the employment of lead acetate when examining the first products with the Ventzke-Soleil-Scheibler instrument. The lead acetate should be prepared according to the German Pharmacopœia (2nd edition, p. 170); sp. gr. 1.235—1.240. Colloidal alumina, prepared according to Vivien's directions, should also be used in all cases. (c.) In clarifying the dark after-products, the use of other substances besides lead acetate and alumina is to be avoided if possible. The charcoal used should be the best bone charcoal which has been washed with hydrochloric acid and subsequently ignited. (d.) Half the standard weight of molasses having been clarified with lead acetate and alumina. The solution is made up to 100, and the optical activity read in a 200 mm. tube. The result of the analysis (disregarding the volume of the precipitate) is multiplied by 2.

*Determination of the Invert Sugar.*—(a.) The syrup is first of all tested qualitatively with Fehling's solution, the procedure being exactly the same as if a quantitative analysis were being made. If there be much reduction, a quantitative analysis should be made. (b.) If a quantitative analysis is required, the sample may be clarified with lead acetate if necessary. The determination should be carried out in detail, as recommended by the Invert Sugar Committee in 1885 (*Zeit. f. Zuckerind.* 1886, 36, 6 and 7). This committee recommended that particular attention be paid to the purity of the reagents used in preparing the Fehling's solution. A good solution should give not less than 16 and not more than 22 mgrms. of copper with pure cane sugar. The use of Soldani's solution is not to be recommended. If less than 50 mgrms. of copper is obtained, the invert sugar is to be considered as *not estimable*. Molasses containing not more than 1 per cent. invert sugar are to be treated in the same way as solid sugar, and the results calculated according to Herzfeld's table. Molasses containing more than 1 per cent. invert sugar are treated in the same way, only less is taken for analysis according to the amount of invert sugar present. The cane sugar and raffinose are estimated according to Clerget's process.

Very full details of the precautions to be observed and the calculation of results are given in the report.—A. L. S.

*Determination of Crude Fibre and Starch.* M. Honig. *Chem. Zeit.* 14, 868 and 902—903.

IN the method about to be described both starch and crude fibre may be determined on the same portion, simply and quickly. In elaborating it the author has made the following observations:—

(1) Starch is converted *quantitatively* into a mixture of dextrin and soluble starch when heated with glycerol to 190° C. as described by Kabsch and Zulkowsky. At 110°—150° C. water vapour is given off, and continues to be evolved while the liquid, at first turbid, becomes opalescent and finally clear at 180°—190° C.

(2) The products of the above reaction contain so little dextrin that they are quantitatively precipitated from their aqueous solution by a mixture of four parts of alcohol and one of ether. This fact and that mentioned under (1) were proved by operating on an air-dried specimen of potato starch, which when converted into sugar direct gave 81.81 per cent. of real starch, as against 81.53, 81.68, and 81.75 when treated by the new method.

(3) Grape sugar is dehydrated and converted into caramel when treated with glycerol at 210° C., and its products yield nothing that might be reckoned as starch.

(4) Cellulose is unaffected by the treatment.

(5) Egg albumen treated by the process described above yields a soluble product, which is however not precipitated by ether alcohol, and may therefore be regarded as unlikely to influence the results.

On these data the following process is based:—2 grms. of the finely-divided substance are placed in a test tube which is ground into the neck of a flask provided with a side tube and containing sulphuric acid; 60 cc. of anhydrous glycerol are poured into the tube, a thermometer inserted as a stirring rod, and the temperature of the outer bath raised until 210° C. is registered. Complete decomposition is usually effected in half to three-quarters of an hour, and the cooling of the inner tube is hastened by removing it from the bath. Its contents is then poured in a thin stream into 200 cc. of 95 per cent. alcohol, stirring well and washing in any particles of cellulose by a fine stream of hot water, not more than 50 cc. being used.

After cooling the mixture, 50—60 cc. of ether are added with the double object of completing the precipitation of soluble starch and rendering the liquid easier to filter. After filtering on a plaited filter and washing with a mixture of five parts of alcohol and one of ether, the greater part of adhering liquid is removed from the filter by spreading it on a porous tile, and the precipitate, consisting of soluble starch and unattacked cellulose, is then washed with a flask with 100—150 cc. of hot water, and heated on a water-bath to dissipate the alcohol. Preferably the digestion is continued under a condenser after the addition of 10 cc. of hydrochloric acid of sp. gr. 1.125 for half an hour, the short heating leaving the cellulose unaffected. The cellulose, or rather crude fibre, is collected on a weighed filter, washed with hot water until the iodine reaction for starch is no longer given, and dried at 110° C. until its weight is constant. Besides cellulose and mineral constituents it contains a little nitrogenous matter, but the quantity is small and a sufficiently close result is got by merely deducting the ash.

The hydrochloric acid filtrate is made up to 250 cc., 200 cc. taken, 12 cc. hydrochloric acid, sp. gr. 1.125, added, and inverted by heating for  $2\frac{1}{2}$ —3 hours in a boiling water bath under a condenser, and titrated with Fehling's solution in the usual way.

Some results by the new method are appended:—

	Cellulose.		Starch.

Wheat.....	6.41	6.29	58.79	59.03
Maize.....	4.94	4.83	51.85	51.73
Oats.....	20.68	20.36	41.30	41.17
Barley.....	6.58	6.72	51.62	51.85

*The Analysis of Celluloid.* H. Zaunschirm. Chem. Zeit. **14**, 903.

CELLULOID generally consists of nitrocellulose and camphor coloured with a little mineral matter or some aniline dye. For most technical purposes a sufficiently approximate method consists in dissolving 0.25—0.3 grm. of the finely-shredded material in 5 cc. of concentrated sulphuric acid in the cup of a nitrometer, stirring with a platinum wire to prevent local heating and charring, and determining the evolved nitric oxide in the usual way, calculating it to nitrocellulose on the assumption that commercial dinitrocellulose has been used in the manufacture, and that therefore the nitrogen found amounts to 10.5 per cent. of the nitrated body, the theoretical percentage being 11.1. The difference between the percentage thus found and 100, gives the camphor, after allowance for any ash if mineral colouring matter has been used; an organic dye, if present, is generally in imponderable quantity. The presence of a carbonate or similar substance capable of evolving gas when treated with sulphuric acid would lead to difficulties, but no such constituent has hitherto been found in commercial samples. It is just possible that though camphor dissolves without evolution of gas in sulphuric acid, and is therefore apparently inert, it may undergo nitration to some extent, and forming a true nitro-derivative, unlike so-called nitrocellulose, may fail to yield its nitrogen when shaken in the nitrometer. This would of course lead to low results, and needs investigation. A more exact scheme suggested by the author, but not hitherto worked by him, consists in dissolving the substance in alcohol or methyl alcohol, and absorbing it in a weighed quantity of purified asbestos or pumice, drying and extracting with chloroform to remove camphor, the loss of weight indicating its amount, and dissolving out the nitrocellulose with absolute methyl alcohol, determining its proportion in the same way, and testing it afterwards if necessary in the nitrometer. Any mineral matter, together with traces of nitrocellulose, is left on the asbestos.—B. B.

*Cause of Error in Tartaric Acid Determinations.* Lampert and Co. Chem. Zeit. **14**, 903. (Compare this Journal, 1890, 420.)

THE numerous disputes and rival methods of analysis of sundry crude materials whence tartaric acid is obtained, have led to the belief that some humous substance must interfere with the ordinary reactions and be the cause of contradictory results. The authors show, however, that alumina is the real cause of the discrepancies, its presence lowering the percentage of acid found by the Goldenberg method, so that it is quite possible if enough be present to find no tartaric acid in a solution known to contain it in large quantity. Thus in a mixture of alum and tartaric acid containing 25 per cent. of the former a deficiency of 5 per cent. was observed, and in one containing 50 per cent. 15.5 per cent. was unaccounted for. How deceptive this may be is shown by the fact that an experienced chemist found 49.4 per cent. in a solution in which after it had been freed from alumina he discovered 80 per cent., a result confirmed by crystallisation on the large scale.

The method for separating alumina, being of some commercial value, is not given.—B. B.

*The Acetyl Numbers of Fats.* B. Wachtel. Chem. Zeit. **14**, 904.

THE validity of the application of the determination of the acetyl number of fats to the estimation of their content of hydroxy fatty acids by Benedikt and Ulzer has been disputed by Lewkowitsch (this Journal, 1890, 660) who has obtained evidence of the absorption of acetic anhydride by fats usually supposed free from such constituents. The author has tested the method on samples of commercial stearic and oleic acids and finds them to possess acetyl numbers of 0 and 6.2 respectively, results quite in accordance with Benedikt's view, instead of the figures 82.29 and 125.55 obtained by Lewkowitsch. (The fact

that oleic acid gives an acetyl number is accounted for by the oxidation which samples have generally suffered before examination.) This discrepancy led the author to examine a sample of beef tallow 15 years old, and one of the fat of the stag 28 years old, with the result that the former gave an acetyl number of 53.7 and the latter one of 40.1; it therefore appears that old samples may contain a sufficient quantity of hydroxy acids to lead to such figures as Lewkowitsch gives, without the accuracy of the method or worker being impugned. The figures for the stag fat are sufficiently interesting to reproduce at length. Acid number 61.7, saponification number 233.0, saponification number for the fatty acids 213.9, Reichert-Meissl number 8.0, acetyl number 40.1. Butter fat on the contrary does not form any large quantity of hydroxy acids on keeping, the acetyl number of one sample examined being only 9.6.—B. B.

*Contributions to the Study of the most Volatile Portion of Coal Tar.* J. Biehringer. Jour. f. Gasbeleuchtung, **33**, 341—345 and 358—359; also Dingl. Polyt. J. **276**, 78 et seq.

See under III., page 928.

*The Estimation of Cyanogen in Gas.* W. Leybold. J. f. Gasbeleuchtung, **33**, 427—428. (Appendix to the paper on "Cyanogen in Gas Manufacture," p. 923.)

A MIXTURE of 30 cc. of ferrous sulphate solution (1:10) and 20 cc. of caustic soda (1:3) is poured into 3 Woulff's bottles having a capacity of about 250 cc. and containing in each 20 cc. of the same soda solution. The mixture should be divided so that the first bottle contains 25 cc., the second 15 cc., and the last 10 cc. 100 litres of gas are passed through the system, by the aid of an aspirator if necessary, the meter employed being protected from the tar by a filter of wool. After the passage of the gas the contents of the bottles are washed out into a flask and boiled for not longer than 15 minutes, then allowed to settle and cool, and filtered into a 500 cc. graduated flask and made up to the mark with water. Of this solution 100 cc. (if the gas be taken from before the first purifier, otherwise 200 cc.) are acidified with hydrochloric acid, and ferric chloride (1:10) added in excess. The blue is filtered off and washed till the washings are colourless, put into a beaker with the filter paper and a little caustic soda added. After decomposition the ferric oxide is filtered off and washed till free from ferrocyanogen. The filtrate is then evaporated in a platinum basin to about 30 cc. and strongly acidified with sulphuric acid (1:10), evaporated to dryness, and ignited. The residue is extracted with 100 cc. of dilute sulphuric acid and washed with 50 cc. of water, and poured into a 250 cc. flask. 1 cc. of copper sulphate solution (1:10) and 10 grms. of pure zinc are added, and the whole allowed to stand till completely reduced. The iron is then determined with permanganate in the usual way.—F. H. L.

See under V., page 936.

## ANALYTICAL AND SCIENTIFIC NOTES.

*Formation of Nitrous Acid and Ammonia from Free Nitrogen.* O. Loew. Ber. **23**, 1443—1447.

IN experiments conducted with stringent precautions against the introduction of either nitrous acid or ammonia, the author found that dry platinum black which does not show even traces of either of these substances when treated with water develops evidences of both of them when treated with a solution of sodium hydroxide; with very dilute solutions (1 NaHO to 1,000 H<sub>2</sub>O), however, reactions for nitrous acid only are obtained. Inasmuch as the test for ammonia (Nessler's) was quite as delicate as the test employed for

the nitrous acid (sulphanilic acid and naphthylamine), the latter fact is regarded as indicating a twofold character in this platinum black and sodium hydroxide reaction:—1. The oxidation of the nitrogen condensed with the oxygen on the platinum black with the production of nitrous acid. 2. The reaction between the nitrogen and water in the presence of strong soda with the production of ammonia.

Passing air into potash holding platinum black in suspension is not a favourable manner of showing the reaction owing to the settling of the black, and it is better to provide an opportunity for the condensation of oxygen (and nitrogen) on the surface of the black. Moist platinum black, 23 to 24 grms. dry, mixed with about 5 grms. of freshly crystallised barium hydroxide and exposed two days in a desiccator over calcium chloride yielded about 0.7 mgrm. of nitrous acid according to an approximate estimation by the sulphanilic acid and naphthylamine reaction. Platinum black well washed with dilute sulphuric acid and water, suspended in absolute alcohol, then in a mixture of alcohol and chloroform, finally in chloroform alone, pressed and dried over sulphuric acid, yielded neither nitrous acid nor ammonia when treated with sodium hydroxide.—D. A. L.

## New Books.

A PRACTICAL TREATISE ON THE EXAMINATION OF AIR. With an Appendix on Illuminating Gas. By J. ALFRED WANKLYN and W. J. COOPER. London: Kegan Paul, Trench, Trübner, & Co., Limited. 1890.

SMALL 8vo. volume, bound in cloth, price 5s., containing Preface, Table of Contents, text covering 80 pages, and an Alphabetical Index. There are nine illustrative plates and six text illustrations. Pages 65 to 80 are devoted to an Appendix "On Illuminating Gas."

The gas apparatus of Hempel is that adopted and employed for the methods of analysis given. The authors say, on page 16, "The introduction of the gas burette, an implement which renders gases almost as manageable as liquids, has greatly aided in the popularisation of gas analysis. The most convenient of these implements is Hempel's. . . ."

The matter is subdivided as follows:—INTRODUCTION. 1. Nature and General Properties of Air and Gases. 2. Chemical Composition of the Atmosphere. 3. The Atmosphere as a whole, its Extent and Distribution. General Atmosphere above Sea Level. The Underground Atmosphere. 4. General Scope of Sanitary Air Analysis. CHAP. I. Endiometry and Complementary Endiometry. CHAP. II. Oxygen ( $O_2$ ). CHAP. III. Nitrogen ( $N_2$ ). CHAP. IV. Carbonic Acid ( $CO_2$ ). CHAP. V. Respired Air. Air from Furnaces. Carbonic Oxide, its Measurement in Air. Physiological Aspect of the Subject. Rules for reporting on Air. APPENDIX. On Illuminating Gas. Tables for Calculation. As regards analysis of illuminating gas, it may be well to refer for more detailed treatment to Wanklyn's "Gas Engineers' Chemical Manual."

The new method of determining carbonic oxide is based on the ascertained facts (1) that carbonic oxide, even in traces in the air, is extracted completely from that air by solution of subchloride of copper in hydrochloric acid, and (2) that when this copper solution is placed in a suitable vessel, the dissolved carbonic oxide can be driven out by means of acid solution of bichromate of potash and may be collected and measured. The method of determining oxygen in the air is an adaptation of the Cavendish and Priestley method, by absorption with nitric oxide gas. "The mode of operation is to add excess of nitric oxide to the sample of air, then to read the contraction. Under the heading, "The Metrical System and English Weights and Measures," the following statement occurs, which may be usefully quoted:—

"In Bunsen's table we read that a litre of nitrogen gas at 760 mm. pressure and zero centigrade weighs 1.2566 grms.

Therefore a cubic foot of nitrogen gas of 760 mm. pressure and zero centigrade weighs 1.2566 ounces avoird."

With regard to the relative importance of air and food the following sentence is quoted: "Between 30 and 40 lb. of air are breathed daily by each of us, and it is hardly an exaggeration to say that our aerial food which enters by way of the lungs dwarfs our liquid and solid food into insignificance." Of the importance of slight variations in the constituents of the air it is said, "There is nothing far-fetched or unreasonable in attaching importance to minute changes in the composition of the air we breathe."

THE CULTURE OF THE SUGAR-BEET AND MANUFACTURE OF BEET SUGAR. By H. W. WILEY, Chemist to the U.S. Department of Agriculture, Division of Chemistry. Washington: Government Printing Office. 1890.

OCTAVO volume, in paper cover, containing Introduction, 245 pages of Subject-matter, illustrated by 11 plates and 49 wood engravings, and an Alphabetical Index. The text is subdivided as follows:—"Early History of the Sugar-Beet and the Manufacture of Sugar therefrom." "History and Progress of the Culture of the Sugar-Beet and the Manufacture of Sugar therefrom in the United States of America." "Beet Sugar Factories at Chatsworth and other Places." "Comparative Development of the Cane and Beet Sugar Industry." "Statistics." "Production of Seed." "Varieties of Beets Grown in France and elsewhere. "Soil, Planting, and Cultivation." "Methods of Cultivation in Bohemia. Harvesting the Beets. Silos and Cellars. The Sugar-Beet in Oregon and Washington Territory. Fertilisers. Studies on the Development of the Sugar-Beet. Contribution to the Chemistry and Physiology of the Sugar Beet. Typical Forms of Sugar Beets. Meteorological Conditions. Recent Experiments looking to the Introduction of the Beet Sugar Industry. Experiments in Iowa. Experiments in Nebraska. "Experiments in South Dakota." Experiments in California. Tables of Work at Factory for each Week from September 16th to November 11th. Yield per Acre. Miscellaneous Experiments at the Factory. Beet Sugar Industry in Canada. Beet Sugar Industry in England. Beet Sugar Industry in the North-West. Use and Treatment of Pulp. Manufacture of Sugar.

## Trade Report.

### TARIFF CHANGES AND CUSTOMS REGULATIONS.

(From the Board of Trade Journal.)

#### SWITZERLAND.

#### Classification of Articles in Customs Tariff.

Note.—Quintal = 220.4 lb. avoirdupois. Franc = 9 $\frac{1}{10}$ d.

The following decisions affecting the classification of articles in the Swiss Customs tariff have recently been given by the Swiss Customs authorities:—

Sesquichloride of chrome (chromium).—Category 16. Duty, 30 cents, per quintal.

Aniline oil (raw aniline).—Category 17. Duty, 1 fr. per quintal.

#### UNITED STATES.

#### Customs Decisions.

Wood-pulp being manifestly not a manufacture of paper, but of wood, and not being intended for paper makers' use, imported expressly for filtering purposes, is dutiable at the rate of 35 per cent. *ad valorem*.

Binetro toluole, a chemical compound composed in part of benzole, which was probably derived from coal-tar,

and in part of nitric acid, which is obtained from a different source, is dutiable at the rate of 25 per cent. *ad valorem*.

Certain naphthol salt held to be dutiable, at the rate of 25 per cent. *ad valorem*, under the provision for chemical compounds and salts, in T. L., 92.

In case of oxygen gas imported in iron bottles or cylinders it was held that such bottles or cylinders are dutiable at the same rate as their contents, the value thereof being included in the dutiable value.

#### CONGO FREE STATE.

##### Export Duties on Caoutchouc and Ivory.

The *Bulletin du Musée Commercial* says that from and after the 1st October (1890), exports of caoutchouc and ivory are to be subjected to the payment of the following duties:—

Caoutchouc, 50 francs per 100 kilogrammes; ivory, 200 frs. per 100 kilos.

#### CANADA.

##### New Customs Tariff.

The following is a statement of rates of import duty now levied under the new Customs tariff of Canada. As the whole tariff is too voluminous for publication in one issue of the *Board of Trade Journal*, it is proposed to continue it in the next number:—

Articles.	Duties Levied.	
	Lb.	Dols. Cts.
Tallow.....	Lb.	0'01
Paraffin wax, stearic acid, and stearin of all kinds	"	0'03
Candles, tallow .....	"	0'02
Do., paraffin wax .....	"	0'05
Do., all other, including sperm.....	25 % <i>ad val.</i>	
Soap, common brown and yellow, not perfumed	Lb.	0'01½
Do., perfumed or toilet, the weight of the inside packages and wrappers to be included in the weight for duty .....	"	0'10 and 10 % <i>ad val.</i>
Castile soap, mottled or white, and white soap.	Lb.	0'02
Soap powders, pumice, silver, and mineral soap, sapollo, and other like articles, the weight of the package to be included in the weight for duty.....	"	0'03
British gum, dressing, sizing cream, and enamel sizing.....	"	0'01
Glue, sheet, broken sheet, and ground .....	"	6'03
Mucilage and liquid glue.....	30 % <i>ad val.</i>	
Saccharin, or any product containing over one-half of 1 per cent. thereof .....	Lb.	10'00
Spirituos or alcoholic liquors distilled from any material, or containing or compounded from or with distilled spirits of any kind and any mixture thereof with water, for every gallon thereof of the strength of proof, and when of a greater strength than that of proof at the same rate on the increased quantity that there would be if the liquors were reduced to the strength of proof. When the liquors are of a less strength than that of proof the duty shall be at the rate herein provided, but computed on a reduced quantity of the liquors in proportion to the lesser degree of strength; provided, however, that no reduction in quantity shall be computed or made on any liquors below the strength of 15 per cent. under proof, but all such liquors shall be computed as of the strength of 15 per cent. under proof, as follows:—		
(a.) Ethyl alcohol or the substance commonly known as alcohol, hydrated oxide of ethyl, or spirits of wine, gin of all kinds, not elsewhere specified, rum, whiskey, and all spirituous or alcoholic liquors, not otherwise provided for .....	Gall.	2'00
(b.) Amyl alcohol or fusel oil, or any substance known as potato spirit or potato oil	Gall.	2'00

#### CUSTOMS TARIFF OF CANADA—cont.

Articles.	Duties Levied.	
	Dols. Cts.	
Spirituos or alcoholic liquors, &c.— <i>cont.</i>		
(c.) Methyl alcohol, wood alcohol, wood naphtha, pyroxylic spirit, or any substance known as wood spirit or methylated spirit; absinthe, arrack, or palm spirit; brandy, including artificial brandy and imitations of brandy; cordials and liqueurs of all kinds not elsewhere specified; mescal, pulque, rum shrub, selvadon and other schnapps; tafia, angostura, and similar alcoholic bitters or beverages .....	"	2'00
(d.) Spirits and strong waters of any kind mixed with any ingredient or ingredients, and being or known or designated as anodynes, elixirs, essences, extracts, lotions, tinctures, or medicines not elsewhere specified .....	"	2'00 and 30 % <i>ad val.</i>
(e.) Alcoholic perfumes and perfumed spirits, bay rum, cologne, and lavender waters, hair, tooth, and skin washes and other toilet preparations containing spirits of any kind, when in bottles or flasks weighing not more than 4 oz. each.....	50 % <i>ad val.</i>	
When in bottles or flasks or other packages weighing more than 4 oz. ....	"	2'00 and 40 % <i>ad val.</i>
(f.) Nitrous ether, sweet spirits of nitre, and aromatic spirits of ammonia .....	"	2'00 and 30 % <i>ad val.</i>
(g.) Vermouth and ginger wine, containing not more than 40 per cent. of proof spirits.	"	0'75
If containing more than 40 per cent. of proof spirits .....	"	2'00
(h.) In all cases where the strength of any of the foregoing articles cannot be correctly ascertained by the direct application of the hydrometer, its shall be ascertained by distillation of a sample, or in such other manner as the Minister of Customs directs.		
Proprietary medicines, to wit, all tinctures, pills, powders, troches or lozenges, syrups, cordials, bitters, anodynes, tonics, plasters, liniments, salves, ointments, pastes, drops, waters, essences, oils or medicinal preparations or compositions recommended to the public under any general name or title as specifics for any diseases or affections whatsoever affecting the human or animal bodies, not otherwise provided for; all liquids 50 % <i>ad val.</i> , all other 25 % <i>ad val.</i> .....	50 % <i>ad val.</i> and 25 % <i>ad val.</i>	
Sulphuric ether .....	Lb.	0'05
Acid, acetic, and pyroligneous, not elsewhere specified, and vinegar, a specific duty of 15 cents for each gallon of any strength not exceeding the strength of proof, and for each degree of strength in excess of the strength of proof an additional duty of 1 cent. The strength of proof shall be held to be equal to 6 per cent. of absolute acid, and in all cases the strength shall be determined in such a manner as is established by the Governor in Council .....	Gall.	0'15 and 0'01 additional.
Acid, acetic, and pyroligneous, of any strength, when imported by dyers, calico printers, or manufacturers of acetates or colours for exclusive use in dyeing or printing, or for the manufacture of such acetates or colours in their own factories, under such regulations as are established by the Governor in Council.....	"	0'25 and 20 % <i>ad val.</i>
Do., muriatic and nitric .....	20 % <i>ad val.</i>	
Do., sulphuric.....	Lb.	0'00½
Do., sulphuric and nitric combined, and all mixed acids .....	25 % <i>ad val.</i>	
Do., phosphate .....	Lb.	0'03
Red and yellow prussiate of potash.....	10 % <i>ad val.</i>	
Aniline dyes not otherwise provided for.....	10 % <i>ad val.</i>	
Blacking, shoe and shoemakers' ink, and shoe, harness, and leather dressing, and harness soap.....	30 % <i>ad val.</i>	
Bluing, laundry bluing of all kinds.....	30 % <i>ad val.</i>

Nutsfoot, olive, sakul, or sesame seed oil.....	20 <sup>7</sup> / <sub>16</sub> <i>ad val.</i>
Vaseline, in bulk .....	Lb. 0'04

## THE McKINLEY TARIFF.

We print below a synopsis of the drug and chemical clauses of the new United States Tariff Bill as they have been amended by the Senate, to whom the Bill was sent up from the House of Representatives. So far as is known no alteration of any importance has been made in the Senate's decisions affecting this part of the tariff by the lower House, and our list virtually represents this part of the Bill as it has received the Presidential sanction. On the whole the House of Representatives has shown itself decidedly more Protectionist than the Senate, and had it had its way many duties would have been advanced or

retained that have now been left undisturbed or reduced. Among the principal reductions or abolitions of duties are those on tannic acid, beeswax, bristles, refined camphor, crude coal-tar, chloroform, dyewoods, nitrous and sulphuric ether, glycerin, indigo, iodine, iodoform, liquorice paste, magnesia, morphia, crude opium, several potash salts, strychnine, refined saltpetre, sulphur, and varnishes. The following are among the chief articles on which the duty has been increased:—Brushes, glue, gelatin, gold-leaf, hops, isinglass, liquorice juice, linseed and linseed oil, mercantiles, olive oil (salad), prepared opium, phosphorus, poppy oil, quicksilver, bichromate and chromate of soda, and sugar of milk. Peppermint oil will not, as stated by us in our editorial note of last week, be made dutiable at the rate of 1 dollar per lb. The House of Representatives proposed that duty, but the Senate struck out that clause and retained the 25 per cent. duty.

—*Chemist and Druggist.*

## THE FINAL SHAPE OF THE MCKINLEY BILL.

*O. P. & D. Reporter* states that the following alterations have been made in the drug and chemical section of the McKinley Bill since it was sent back from the Senate to the House of Representatives:—Tannic acid has been changed to 75 c. per lb.; barytes to \$1-12 per ton; manufactured ditto to \$6-72 per ton; bronze powders to 12 c. per lb.; bay rum to \$1-50 per gallon; bristles to 10 c. per lb.; brushes to 10 per cent. *ad val.*; cork and cork bark to 10 c. per lb.; manufactured cork to 15 c. per lb.; Dutch metal-leaf to 8 c. per package; hemlock extract to  $\frac{1}{2}$  c. per lb.; liquorice paste and juice to  $5\frac{1}{2}$  c. per lb.; logwood extract to  $\frac{7}{8}$  c. per lb.; peppermint oil to 80 c. per lb.; phosphorus to 20 c. per lb.; ground sumac to  $\frac{1}{4}$  c. per lb.; and extract to  $\frac{7}{8}$  c. per lb.; sulphate of soda to \$1-25 per ton; tallow to 1 c. per lb.

## UNITED STATES.

*The New American Tariff.*

The special point in connexion with the new American tariff regulations is the requirement of the consular and Customs authorities that manufacturers and shippers of merchandise to the United States should make a declaration showing (1) the cost of the raw goods and their manufacture combined; (2), all other charges incident to preparing goods ready for shipment, and (3) a percentage—not less than 8 per cent. on items Nos. 1 and 2—to bring the value up to market value. In view of the new law it is felt that there is no option but to give the required information to the consular and Customs authorities, but serious objection is taken to supplying particulars to consignees in America of the cost of producing all goods that are shipped, and the private charges thereon. The form above referred to is to be filled up in triplicate, one copy being for the Consul on this side, one for the Customs authorities, and one for the consignee. There is a natural objection to supplying the third form, and the London Chamber of Commerce is in correspondence with the American Consul in London with the object of ascertaining how far any modification of the regulations is possible. In this connexion the following paragraph is of interest:—

*Instructions to the Customs under the McKinley Bill.*

The following circular instructions have been distributed by the Secretary to the Treasury of the United States to collectors and other officers of Customs to govern proceedings under the Customs administrative law—otherwise known as the McKinley Bill—which came into effect on the 1st August:—(I.) It is proper that certain general principles should be announced which in the opinion of the department must govern the application of the various provisions of the new law to the current business at the several ports. (II.) The duties upon imported merchandise are held to attach to the merchandise at the time of its arrival in a port of the United States. The date of arrival of merchandise intended for immediate transportation without appraisement will be that of its arrival in an exterior port of the United States. Therefore the assessment of duties upon goods which arrive on or before July 31st instant, will be made on the basis of the present laws, even if entry of such merchandise shall be deferred until after the 31st day of July. (III.) Invoices authenticated before the 1st day of August, proximo, will be accepted at any time thereafter, provided the consular certificates conform to the present requirements of law. Consular certificates after the 1st day of August must conform to the requirements of the Act of June 10th, 1890, but in view of possible difficulties in obtaining an immediate conformity with such requirements invoices which are accompanied by certificates not in all respects in accordance with the law of June 10th, 1890, will be regarded as informal and will be accepted as *pro forma* invoices, under bond to produce a properly certified invoice within six months from the date of entry. (IV.) In the entry of merchandise bills of lading drawn to the order of persons doing business as bankers and indorsed by them to the order of the actual importers of the merchandise specified

therein will be accepted when presented by such importers in making entry of said merchandise the same as if originally drawn to their order. (V.) After July 31st, 1890, no damage warrants shall be issued by collectors of Customs, but proceedings under warrants issued on or before that date will be carried on as under the present law. (VI.) In case of protest against the action of collectors or of appraisers which may be filed on or after the 1st day of August, proceedings will be governed by the law of June 10th, 1890, even when such protests shall relate to merchandise which shall have arrived on or before July 31st, 1890. But all proceedings on the estimate and assessment of duties upon such merchandise and upon the original appraisement and liquidation of the same shall conform to the requirements of the law under which the goods were imported. Invoices covering goods which are in bonded warehouse on August 1st will not therefore require re-liquidation under the new law. (VII.) A list will be furnished prescribing such fees as will be charged after August 1st, 1890. All other fees are held to be abolished under the new law. (VIII.) Attention is called to the provisions of section 19 of the new law which define the dutiable value of imported merchandise to consist of all costs and charges that attach to the goods in condition packed ready for shipment to the United States. All such costs and charges which are specified in the invoice will therefore be included in determining the value for the original estimate of duty. (IX.) It is the opinion of the department that section 20 of the new law permits the retention of merchandise in bonded warehouse for more than one year, and not more than three years from date of importation without the imposition of the additional duty of 10 per cent. provided by section 2970 Revised Statutes upon its withdrawal for consumption.—*London Chamber of Commerce.*

## EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

## GERMANY.

The following figures indicate the principal chemicals (in quantities of 100 kilos. = 2 cwt.) exported from Germany to Great Britain during the last three years:—

	1887.	1888.	1889.
Ultramarine .....	12,352	10,322	20,053
Alum, alumina .....	19,568	18,836	26,891
Soda, calcined .....	4,098	2,576	3,500
Soda, crystals .....	3,793	334	619
Potash .....	16,647	16,257	15,092
Alizarine .....	24,305	29,050	31,637
Aniline and transition products to tar colours .....	1,563	1,729	2,653
Aniline dyes and tar colours .....	11,385	11,848	13,866
White lead and zinc white .....	71,130	79,150	117,974
Chloride of potash .....	254,999	153,215	148,315
Glycerin, refined and crude .....	2,338	4,644	7,550
Sulphate of potash .....	36,912	44,579	57,335
Mineral waters, artificial and natural	25,956	25,832	33,400
Soda and sulphate of soda .....	8,022	4,472	5,548
Saltpetre (soda) .....	4,311	5,292	11,777
Saltpetre (potash) .....	14,091	16,637	40,044
Vitriol of every description .....	506	1,257	3,125
Tartaric acid .....	6,983	8,019	8,107

The following are the principal exports of chemicals from Great Britain to Germany:—

	1887.	1888.	1889.
Caustic soda.....	12,090	9,365	8,576
Alum, alumina .....	1,270	526	447
Chloride of lime .....	29,787	40,819	33,910
Dye-wood extract .....	2,295	2,766	3,134
Bicarbonate of soda.....	3,637	4,884	6,704
Calced soda.....	9,434	4,094	3,387
Soda crystals .....	3,297	1,056	281
Ammonia, carbonated sal-ammonia, &c.	5,062	5,327	8,858
Sulphate of ammonia .....	245,519	246,004	278,295
Aniline dyes, &c.....	1,274	1,934	925
Cutch and gambier .....	19,735	16,976	33,758
Cinchona .....	25,147	22,894	27,658
Chlorate of potash .....	5,060	4,062	5,312
Chromate of potash .....	5,954	8,416	9,473
Dye-woods .....	30,340	21,324	52,133
Glycerin, refined and crude.....	10,034	15,221	18,616
Indigo.....	5,238	6,132	7,489
Bone black .....	14,697	29,499	54,219
Sulphate of soda.....	3,243	824	2,430
Saltpetre (Chili) .....	17,466	46,234	52,341
Sulphur .....	2,369	6,289	4,129
Turpentine, &c.....	5,622	6,497	6,799
Vitriol.....	926	734	6,373
Quicksilver.....	1,263	1,078	1,134
Pepper.....	16,280	15,541	17,668
Tea.....	6,123	6,475	6,293
Cotton oil .....	37,987	34,828	39,628
Linseed oil.....	170,058	199,799	246,610
Olive oil .....	1,204	1,918	1,174
Palm and coconut oil .....	67,083	65,762	65,128

#### MEXICO.

##### Imports from United Kingdom into Vera Cruz.

Last year the imports from the United Kingdom into Vera Cruz increased 76 per cent., from all other countries 27 per cent., in spite of the fact that cottons (of which a large percentage of the British imports consists) pay an average duty of 133 per cent., and that the average of all dutiable goods imported from this country is 121 per cent., while the average of goods from all countries is "only" 91 per cent.

Drugs pay an average duty of 60 per cent. *ad valorem*. The value of the imports during the last two years has been as follows:—

	1889.	1888.
	£	£
Drugs from United Kingdom .....	13,650	18,513
Drugs from all parts.....	120,632	95,005
Quicksilver from United Kingdom...	50,695	42,951
Quicksilver from all parts.....	100,605	85,384

#### Openings for Industries in Mexico.

The duties which protect the national industry are made to press so heavily on ordinary articles that none but the rich purchase those imported, "everyone is forced to consume national products" being a maxim of the Mexican lawgivers. The duties on glassware are from 3 to 45 centavos per kilo., which has to be paid even on articles broken in transit. Raw materials for making articles of this kind abound in the country, but the national products are still so dear that the poorer classes cannot procure enough for their requirements, and they use the most ordinary qualities. Mexican factories only produce window glass and glass bottles at fabulously high prices; an 18-inch square of common glass costs 75 centavos (equal to about 1s. 10½d.), while itinerant dealers buy up old bottles at the rate of about 3s. 4d. the dozen. As to the chemical industry, the Belgian Consul in Mexico is of opinion that an establishment engaging therein would be excessively productive. Only two chemical factories exist at present, which turn out specially sulphuric, hydrochloric, and nitric acids, securing enormous profits. Foreign sulphuric acid sells at 16 centavos per kilo., hydrochloric acid at 40 centavos, and nitric acid 65 centavos per kilo. On the other hand, Mexican-made sulphuric acid sells at 12 to 14 centavos the kilo. The dearthness of sulphuric acid is such that many metallurgical works make their own acid. Cheap acid would not only "regenerate" industry, but those who produce it would "doubtless do brilliant business." In other allied branches the Consul is also of opinion that there are suitable openings for manufacturers who will study the matter.

#### SIAM.

##### Sapan Wood.

The export of this valuable dye-wood from Bangkok has decreased each year since 1884, when the export was 3,079 tons. In 1887 it fell to 1,772 tons, and in 1888 to 1,372 tons. The sapan wood forests are, it appears, much exhausted, and without forest regulations there is danger of the wood ceasing to be an article of export. The supply from the Raheng district, whence most of the wood formerly came, has now almost ceased, and that which finds its way to Bangkok is derived chiefly from the Lakhon forests, the trees being torn up by the roots and floated down by way of Raheng to Bangkok. Most of the sapan wood shown in the returns is exported in the form of dunnage with rice cargoes.

##### Cutch.

The returns show an export of cutch to the value of 411, only from Bangkok. The bark of the cutch tree, which grows abundantly in the districts of Lakhon and Phræ in Northern Siam, is boiled into conical lumps the size of a fowl's egg by the inhabitants of those provinces for local use; but the industry appears to be little developed. The admixture of a small piece of cutch with the other ingredients of a quid of betel is considered a delicacy amongst the Laos. The use of the bark as a dye is little known or cultivated by them.

## MISCELLANEOUS TRADE NOTICES.

## THE COST OF LABOUR IN THE UNITED STATES.

Some useful figures have been published by the Boston, Mass., Labour Bureau, showing the proportion to the cost of certain goods, manufactured in that State, of wages, raw

material, and general expenses, such as insurance, taxation, rent, &c. The following are some figures representing the cost of manufacturing chemicals in a wholesale way, the figures in the first column representing the quantities upon which the cost was actually tested:—

	Quantity Experimented on.	Raw Material.	Wages.	General Expenses.
		Per Cent.	Per Cent.	Per Cent.
Compound chemical preparations (unenumerated) .....	1,000 galls.	95.24	1.76	..
Sulphuric acid .....	1 ton	53.41	14.87	32.22
Prussian blue, needles .....	2,000 gross	15.65	13.09	71.26
Illuminating oil .....	Per barrel	67.50	6.79	25.71
Copperas .....	3,185 tons	41.66	22.91	35.43
Brunswick black (Japan) .....	Per lb.	70.59	23.53	5.88
Green paint .....	1,000 lb.	90	10	..
Mixed paints (unenumerated) .....	Per gall.	90	10	..
Candles .....	Per lb.	95.83	4.17	..
Soap .....	Per cwt.	66.67	8	25.53
Soft soap .....	20 barrels	75	12.50	12.50
Fuller's earth (mineral soap) .....	Per box	80.47	10.53	..
Soap for textiles .....	980 tons	61.36	8.79	30.05
Powdered soap (large quantity) .....	Per lb.	57.14	7.14	35.72
Powdered soap .....	1,400 lb.	77.78	22.22	..
Tallow .....	175 tons	95	4.80	..
Tallow oil .....	100 lb.	93.75	6.25	..
Glue .....	150 tons	86.80	10.41	2.79
Starch .....	Per barrel	81.45	18.55	..
Dyestuffs .....	Value, \$72,000	..	20.50	..
Oils and illuminants .....	Value, \$97,000	..	5.92	..
Paints, colours, and heavy chemicals .....	Value, \$164,000	..	16.50	..

The maximum weekly wage of operatives employed in the preparation of chemicals is 3*l.* to 4*l.*; in dyestuffs the average wage is 2*l.* to 2*l.* 8*s.*; in the oil trade, also 2*l.* to 2*l.* 8*s.*; in paints and crude chemicals, 2*l.* 8*s.* to 3*l.*; in dye and bleaching works, about 1*l.* 8*s.* to 1*l.* 10*s.*

## MANGANATE OF SODA.

At the usual weekly meeting of the members of the London county council on October 21st, held at County Hall, Spring Gardens, Charing Cross, Sir J. Lubbock, Bart., M.P., presiding, one of the committees said the chemist to the council had reported that during the past summer there had been used in deodorising the sewage 1,654 tons of manganate of soda, and 749 tons of sulphuric acid, at a cost of £4,560*l.* 18*s.* 1*d.* The cost for similar operations in the year 1889 was 25,305*l.* In order that the most advantageous terms might be obtained from contractors, who could work to better advantage when ample notice was given, the committee recommended: "That an advertisement be issued inviting tenders for the supply of 3,500 tons of manganate of soda of 30 per cent. quality, and 1,000 tons of sulphuric acid, during the summer of 1891." This was agreed to.—*Chemist and Druggist.*

## TRADE IN CUBA.

Trade in Cuba during 1889 was satisfactory on the whole, and the output of iron ore also augmented. The exports of wax were 34,430 lb., against 32,316 lb. of the previous year. Four-fifths went to the United States, and the rest to Germany and Spain. The average price was 2*l.* 8*s.* 6*d.* per 100 lb. The exports of iron ore are, so far, confined to the output of the Juragua Iron Company, which is steadily on the increase. In 1889 the production amounted to 248,430 tons of ore, containing on the average 64 per cent. of metallic iron, against 202,625 tons in the preceding year. The ore is not sold in Cuba, but is sent to the United States for account of the company. The price realised in the States is not given, but it costs the company 6*s.* 4*d.* per ton put on board ship at St. Jago, exclusive of first cost of the mines, and is yielding a profit of from 2 dols. to 2½ dols.—say 8*s.* 1*d.* to 10*s.* 5*d.*—per ton. Manganese is comparatively a new item of export, having only commenced in 1888, during which year 1,981 tons of ore, containing from 50 to 55 per cent. of metallic manganese, were shipped to the United States, and 604 tons went on last year. This industry is on the increase, and yields a fair profit to the miners. It costs about 30*s.* to put on board ship at St. Jago, excepting the ore from some mines at a further distance, which costs about 12*s.* per ton more.—*Ironmonger.*

## GERMAN PHARMACEUTICAL INDUSTRY.

The following interesting figures are published in the *Chem. Zeit.* as indicative of the increase or decrease in the consumption of some important drugs and dyestufferies in Germany. The figures represent quantities of 1 ton (20 cwt.) weight:—

Year.	Dyewoods.	Indigo.	Cinchona.	Copra, Cocoa, and Palm Nuts.	Cochineal.
1836-40	9,007	361	..	..	..
1846-50	12,900	884	..	..	..
1850-60	20,603	654	..	..	..
1871-75	20,931	1,050	1,028	21,146	526
1881-85	41,212	1,181	2,876	60,651	111
1888	55,733	1,016	4,671	100,258	77
1889	53,173	1,119	5,120	101,832	35

Year.	Cutch.	Gum Arabic and Tragacanth.	Shellac	Olive Oil in Casks.	Camphor.
1872-75	3,513	1,393	..	..	..
1876-80	4,292	1,084	..	..	..
1881-85	5,972	1,513	1,137	19,895	..
1888	5,754	1,190	1,396	9,795	378
1889	5,791	1,318	919	11,213	353

## CHEMICAL WORKS IN VICTORIA.

According to a Government paper recently issued, there are in the colony of Victoria 11 chemical works, employing in all 188 persons, and with plant worth 26,100/. Surgical instrument factories appear to the number of five, with 28 hands and plant worth 1,465/. The aerated waters industry includes 160 works, employs 1,183 persons, and owns plant worth 124,688/.

## BOARD OF TRADE RETURNS.

## SUMMARY OF IMPORTS.

	Month ended 30th September	
	1889.	1890.

## Monthly Patent List.

\* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

## I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

## APPLICATIONS.

14,543. E. F. Edgar. Improvements in furnaces. Complete Specification. Filed September 16. Date applied for, March 27, 1890, being date of application in United States.

14,846. W. H. Kennedy. See Class X.

15,008. H. H. Hazard. See Class II.

15,254. J. Joly. Improved method of desiccating substances. September 26.

15,277. F. M. Robertson. A new or improved process for desiccation or evaporation. September 26.

15,604. W. Cole. An improved apparatus for supplying air under pressure. October 2.

15,605. W. Cole. An improved apparatus for supplying air under pressure. October 2.

15,659. F. Garside. An improved method for the evaporation of water or other liquids in order to extract materials held in solution, and apparatus therefor. October 3.

15,698. R. A. Robertson (of the Firm of The Mirreles, Watson, and Varyan Co., Lim.) and D. Ballingall. Improvements in apparatus for evaporating, concentrating, and distilling liquids. October 1.

15,930. C. Kellner. See Class XIX.

15,931. C. Kellner. See Class XIX.

15,975. G. J. Davis and E. Jones. An improved manufacture of compound suitable for forming joints in steam cylinders and pipes, also vessels for containing water, acids, vapours, and for other purposes. October 8.

15,976. G. J. Davis and E. Jones. An improved manufacture of compounds suitable for coverings for floors, walls, ceilings, also for tubes, insulating coverings, and other purposes. October 8.

16,192. A. Estrayer. Improvements in filter presses and oil presses. October 11.

16,251. H. H. Badams. Improvements in filter presses. October 13.

16,263. W. S. Dimes. Improvements in apparatus for agitating and mixing liquids. October 13.

16,326. T. Slater. Improvements in multiple evaporating apparatus. October 14.

16,381. J. Dunn. Improvements in apparatus for drying semi-liquid granular or pulverulent substances. October 15.

16,404. T. E. Caddy. Improvements in or relating to furnaces. October 15.

16,528. T. E. Wilson. Improvements in apparatus for evaporating, distilling, or concentrating liquids. October 17.

16,552. F. W. Scott, jun. Improvements relating to vacuum and evaporating pans. October 17.

16,557. W. P. Thompson.—From J. L. J. Vzn, Holland. Improvements in pumps for viscous, pulpy, or semi liquid substances. October 18.

#### COMPLETE SPECIFICATIONS ACCEPTED.\*

1889.

16,452. F. Hocking. Apparatus for evaporating, heating, cooling, and condensing. October 22.

19,103. G. H. Lloyd, S. S. Lloyd, jun., and W. S. Sutherland. Distributing and mixing the inflammable gases or vapours and air used in gas or blow-pipe welding, and apparatus therefor. October 15.

19,533. S. Alley. Rotative furnaces for roasting ores, &c. October 8.

19,906. W. H. Lonsdale. Cement for covering boilers, steam-pipes, &c. September 21.

1890.

10,856. A. Silverberg and C. Detering. Carbonising apparatus. October 8.

11,686. S. M. Lillie. Evaporating apparatus. October 1.

11,747. G. W. Haslam and P. Cornish, jun. Drying and desiccating wet substances. October 22.

12,260. A. W. Ellis. See Class XVII.

12,505. S. Seckendorf. Drying and pressing apparatus for granular and pasty matters. October 1.

13,930. H. E. Newton.—From W. J. Macdonagh and others. Appliance for injecting liquid and gaseous fuel into furnaces. October 8.

14,059. H. E. Hansen. Apparatus for complete evaporation of solutions. October 22.

## II.—FUEL, GAS, AND LIGHT.

### APPLICATIONS.

14,526. J. R. Shearer. A method of using the dead or heavy oils for illuminating and heating purposes. September 15.

14,618. W. B. Lampard. Improvements in apparatus for charging inclined gas retorts. September 16.

14,648. J. Balbirnie. Obtaining and applying natural gas. September 17.

14,649. J. Balbirnie. Obtaining and applying natural gas. September 17.

14,650. J. Balbirnie. Obtaining and applying natural gas. September 17.

14,651. J. Balbirnie. Obtaining and applying natural gas. September 17.

14,652. J. Balbirnie. Obtaining and applying natural gas. September 17.

14,720. J. Ruseoc. Improvements in apparatus for charging and drawing gas retorts. September 17.

14,737. D. Rylands and D. Johnson. Improvements in and in the manufacture of firelighters. September 18.

14,832. J. H. W. Stringfellow. Improvements in the treatment of hydrocarbons. September 19.

14,873. E. Sparshott and The Atlas Engine Co., Lim. Improvements in and relating to apparatus for the manufacture and storage of oil-gas. September 20.

14,906. C. W. Jones. Improvements in the revivification of materials employed for the purification of coal-gas, and in the treatment of the residues. September 20.

14,925. J. H. Parkinson. Improvements in the means of obtaining and separating oxygen and nitrogen from atmospheric air. September 22.

14,968. W. R. Lake.—From N. O. Goldsmith, United States. Improvements in and relating to apparatus for withdrawing coke from ovens, and for similar purposes. Complete Specification. September 22.

14,988. W. Smith. Improvements in the manufacture of artificial fuel. September 23.

15,008. H. H. Hazard. System for condensation, treatment, and utilisation of smoke, gases, fumes, and chemical products arising from furnaces and fireplaces of all kinds. September 23.

15,012. W. B. McClure, E. Corning, T. Hodgson, J. E. McWilliams, and J. W. White. Improvements in artificial fuel and in the process of making the same. Complete Specification. September 23.

15,158. J. H. Parkinson. Improvements in the means of obtaining and separating oxygen and nitrogen from atmospheric air. September 25.

15,379. J. Platt. Improvements in apparatus and appliances for obtaining more perfect combustion of fuel in the furnaces of steam generators. September 29.

15,388. J. F. Braidwood. An improved method of, and apparatus for, charging retorts for the manufacture of gas and other like purposes. September 29.

15,742. E. T. Ruthven-Murray. Improvements in machinery for charging and drawing gas retorts. October 4.

15,998. J. C. Lawson. Improvements in the manufacture of oxygen. October 9.

16,167. J. H. Hilton. Improvements in apparatus for carburetting gases. October 11.

16,207. F. Siemens. Improved means of utilising waste gases in regenerative gas furnaces. October 11.

16,213. A. Coze. Improvements in apparatus for charging inclined gas retorts. October 11.

16,410. T. W. Smith. Improvements in the manufacture of water-gases and of illuminating gas. October 16.

16,517. G. E. Davis and A. R. Davis. The purification of coal gas, and treatment of the by-products. October 17.

\* See Note \* on previous page.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

- 11,920. F. J. Jones. Production of coke. October 15.  
 15,947. J. H. Fergusson. Manufacture of illuminating gas. October 8.  
 16,009. J. Lawson. Oil-gas producing apparatus. October 22.  
 16,795. D. Dixon. Method and apparatus for generating gas. October 15.  
 17,131. J. Jones. Method and apparatus for burning fuel, debris, and water, consuming smoke, and utilising the products. October 22.  
 17,480. J. H. Wood. Artificial fuel. September 24.  
 17,535. F. B. Dortmund. Manufacturing coke. September 24.  
 17,945. J. Morley. Manufacture of firelighters. October 8.  
 17,954. T. D. Rock. Improvements in coking, and in coke ovens and plant. October 15.  
 18,543. J. E. Butterworth. Firelighters. October 8.  
 18,831. Kirkham, Hulett, and Chandler, Lim., and J. Chandler. Apparatus for separating tar and other impurities from gas. October 15.  
 19,121. W. G. Robinson. Apparatus for generating and burning gas from heavy oils or carbonaceous fluids. October 1.  
 20,031. W. Smith. Improved gas-lighting. October 22.  
 20,083. F. Siemens. Regenerative gas furnaces and gas-producers. October 22.  
 20,368. W. L. Wise.—From L. Senet. Coke ovens. October 22.

1890.

- 11,784. J. W. C. C. Schirm. Producing intense light by magnesium or other glowing matters. October 22.  
 12,036. I. Lilley and G. H. Hopkins. Manufacture of compressed fuel, and apparatus therefor. September 24.  
 12,860. J. T. Key. Process and apparatus for manufacturing gas. September 24.  
 13,033. F. Leonard and E. W. Harding. Manufacture of artificial fuel. September 24.  
 13,767. J. Gridley. Rendering wood highly inflammable. October 15.

## III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

## APPLICATION.

- 16,444. J. C. Hamilton. Improvements in obtaining substances of the class comprising phenol and cresol. October 16.

## IV.—COLOURING MATTERS AND DYES.

## APPLICATIONS.

- 14,620. J. Y. Johnson.—From The Badische Anilin and Soda Fabrik, Germany. The manufacture and production of new substantive dyestuffs and of copper compounds thereof on the fibre. September 16.  
 14,621. B. Willeox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. Improvements in the manufacture and production of rosaniline derivatives or leuco bodies of the tri- or di-phenyl-naphthyl-methane series and colouring matters therefrom. September 16.

11,836. J. Y. Johnson.—From The Badische Anilin and Soda Fabrik, Germany. The manufacture and production of a sulpho-acid suitable for dyeing and printing. September 19.

15,120. O. Imray.—From The Society of Chemical Industry, Switzerland. A process for the manufacture of black colouring matters. September 21.

15,246. J. Wright. Improvements in black dyeing materials composed of mixtures of animal and vegetable fibre. September 26.

15,345. B. Willeox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture and production of blue colouring matters or dyestuffs. September 27.

15,346. S. Pitt.—From L. Cassella and Co., Germany. The manufacture of azo-dyestuffs, and of materials for their production. September 27.

15,347. S. Pitt.—From L. Cassella and Co., Germany. The production of azo colours in substance or on the fibre. September 27.

15,674. J. R. Geigy. Production of brown colours which may be diazotised on fibre, and then combined with phenols or amines. October 3.

15,743. W. Davison. Improvements in colours. October 4.

15,778. M. Lange. New process of separating orthotoluid, sulphonic and paratoluid-sulphonic acids. October 6.

15,803. J. Y. Johnson.—From The Badische Anilin and Soda Fabrik, Germany. The manufacture and production of a new naphthalene derivative suitable for use in the manufacture of dyestuffs. October 6.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

- 18,247. C. Romen. Rendering dry alizarine fit for colouring and printing purposes. September 24.  
 18,351. B. Willeox.—From The Farbenfabriken vormals F. Bayer and Co. Production of direct-dyeing yellow colouring matters. October 1.  
 18,517. B. Willeox.—From The Farbenfabriken vormals F. Bayer and Co. Production of azo-colouring matters. September 24.  
 18,519. B. Willeox.—From The Farbenfabriken vormals F. Bayer and Co. Production of direct-dyeing colouring matters. October 8.

20,219. J. Imray.—From La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis. Manufacture of azo-oxyaniline, and of colouring matters therefrom. October 22.

20,292. J. Imray.—From La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis. Production of a substituted metadiamine, and of colouring matter therefrom. October 22.

20,668. J. Y. Johnson.—From The Badische Anilin and Soda Fabrik. Manufacture of colouring matters suitable for dyeing and printing. October 22.

20,678. O. Imray.—From The Farbenfabriken vormals Meister, Lucius, and Brüning. Production of compounds of the diphenylmethane group and the rosaniline series. October 22.

## V.—TEXTILES, COTTON, WOOL, SILK, Etc.

## APPLICATIONS.

15,170. G. Schuler. Improvements in the manufacture of linoleum, lincrusta, cere-cloth, and the like. September 25.

15,580. C. R. F. Schloesser and J. M. Campbell. Improvements in the manufacture of certain waterproof or water-repellant materials and fabrics. October 2.

15,758. M. Lister. Improvements in machinery for pulling and breaking silk waste, rabbits' down, fur, and other light fibre. October 6.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

17,137. E. Johnson.—From T. Barrows. Means and apparatus for ungumming, &c. flax and other like fibres. October 8.

1890.

8296. The Serrell Automatic Silk Reeling Company, Limited. Preparing cocoons for reeling. October 22.

10,856. A. Silverberg and C. Detering. Apparatus for carbonising wool. October 8.

## VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

## APPLICATIONS.

14,829. F. Walton. A process for bleaching ground cork. September 19.

14,839. O. Hoffmann. Process and appliances for washing, bleaching, and dyeing fibrous materials. September 19.

14,897. W. P. Thompson.—From F. Kornfeld, Austria. Improvements in dyeing, bleaching, washing, or otherwise treating cops of yarn or the like, and apparatus therefor. Complete Specification. September 20.

15,142. M. J. Norwood. Making stained or coloured made paper equal in appearance to stained glass, and rendering same clear by the use of turpentine, varnish and copal, terebene, pine oil, boiled oil, linseed oil, bicarbonate of potash, size, and dextrin. September 24.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

18,073. B. Willeox.—From The Farbenfabriken vormals F. Bayer and Co. Dyeing and printing animal and vegetable fibres with dinaphthyl-diquinhydrone or with betanaphthoquinone or tetraoxydinaphthyl. October 8.

18,115. A. Graeniger. Machines for dyeing, bleaching, &c. fibres. September 24.

19,408. C. Weber-Jacquel. Apparatus for dyeing, bleaching, &c. October 8.

19,863. C. Corron. Apparatus for dyeing and otherwise treating textile fabrics. October 15.

20,064. R. Holliday. Producing azo-colours on cotton or other vegetable fibres. October 1.

1890.

11,580. W. Marriott. Mordant for black dyeing. October 15.

12,900. T. Strahan. Colouring or decorating wall papers or coverings. October 8.

12,950. H. Thies and E. Herzig. Bleaching. September 24.

13,048. S. Pitt. From A. Smith and Son's Carpet Co. Dyeing apparatus. October 8.

## VII.—ACIDS, ALKALIS, AND SALTS.

## APPLICATIONS.

14,542. A. Boake. Improvements in the manufacture of phosphoric acid. September 16.

14,544. H. J. Allison.—From M. M. Monsanto, United States. Improved process for purifying brines. Complete Specification. September 16.

14,931. J. H. Parkinson. Improvements in the method of producing a porous mass of permanganate of potash. September 22.

15,159. J. H. Parkinson. Improvements in the method of producing a porous mass of permanganate of soda. September 25.

15,394. E. Richters. Process for utilising the silicic fluoride obtained by the treatment of certain phosphates with sulphuric acid. September 29.

15,416. R. D. Bowman. Improved process for the production of manganate of soda. September 29.

15,637. T. Goode and A. Smith. An improved process for recovering sulphur from alkali waste. October 2.

15,648. J. Leith. Improvements in the production of sulphhydrate of calcium to be used in the manufacture of alkali and sulphuretted hydrogen, and in apparatus therefor. Complete Specification. October 3.

15,942. J. A. Nettleton. Improving the process of vinegar making. October 8.

16,049. R. Haldan.—From the Viscount de Lambilly, France. New process for manufacturing alkaline or alkaline-earth cyanides through atmospheric nitrogen, and the application of the same to the production of ammonia. Complete Specification. October 9.

16,218. M. Netto. Improvements relating to the manufacture of hydrated oxide of iron. October 11.

16,233. H. C. Bull. Improvements in processes for the manufacture of sulphate of lead, and apparatus therefor. October 13.

16,460. D. Gamble.—From A. R. Péchiney, France. Improvements in the manufacture of chlorate of soda. October 16.

16,505. J. Beveridge. Improvements in the treatment of bisulphites, and in apparatus therefor. October 17.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

17,217. F. M. Lyte and J. G. Tatters. Recovery of chlorine from solutions of calcium chloride, magnesium chloride, the residual liquors of the ammonia-soda process, and other residues. October 8.

17,218. F. M. Lyte and J. G. Tatters. Production of hydrochloric acid from certain industrial residues, together with recovery of sulphur and oxide of magnesium. October 1.

17,888. F. M. Spence and D. D. Spence. Manufacture of alum. October 22.

18,356. E. Bowen. Manufacture of ammoniacal salts. October 22.

18,904. W. P. Thompson.—From E. de Lom de Berg. Manufacture of picric acid by crude phenols. October 1.

1890.

5488. W. Donald. Obtaining chlorine. October 1.

## VIII.—GLASS, POTTERY, AND EARTHENWARE.

## APPLICATIONS.

14,519. D. Chapman. Improvements relating to the decoration of china, earthenware or pottery and glass goods. September 15.

14,628. J. Sherwin. Improved devices for supporting earthenware while being fired. Complete Specification. September 16.

14,771. J. I. de Jongh. Glass tiles suitable for being used in conjunction with sheets of corrugated iron in the making of roofs and the like. September 18.

14,935. H. R. Lumley. An improved process and apparatus for producing glassware. September 22.

14,983. J. T. King.—From E. Jones and J. A. Jones, United States. Improvements in apparatus for the manufacture of glassware. Complete Specification. September 23.

15,197. H. C. Bull and P. Hargan. An improved process for the manufacture of pure silicates for use in glass making from common sand and pure metallic chlorides, the recovery of the hydrochloric acid arising therefrom, and apparatus therefor. September 25.

15,301. D. Rylands. Improvements in or applicable to machinery for the manufacture of bottles or other hollow glass ware or pressed ware. September 27.

15,468. J. B. Turnhurst. Decorating bisquit or unglazed china and earthenware or other similar articles or bodies. September 30.

15,753. W. B. Fitch. Improvements in the manufacture of glass bottles and similar articles. October 4.

16,112. W. Boulton. Improvements in machinery for manufacturing cups and other articles in pottery ware. Complete Specification. October 10.

16,131. J. W. Payne. A new or improved portable or fixed continuous firing kiln for burning and staining glass, china, tiles, enamels. October 11.

16,153. D. Rylands. Improved means of manufacturing glass conduits or tubes for electrical or other purposes. October 11.

16,369. D. Rylands. Improvements in machinery for the manufacture of glass bottles and other glass ware. October 15.

16,422. C. K. Mills.—From J. B. Granjon and F. Allemand, France. An improved process for moulding and firing hollow articles. October 15.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

16,696. F. R. Rostaing, L. A. Garchey, and N. E. Geille. Manufacture of vitreous material suitable for artificial marble, stained glass, &c. October 8.

18,951. W. J. Hague. Kilns for burning clay goods, furnaces, and like fires, and utilising heat from gas-producers in connexion therewith. October 1.

17,933. D. Rylands and J. W. Horner. Means for withdrawing molten glass or metal from furnaces, and controlling the outflow thereof; applicable for conveying liquid chemicals from larger to smaller vessels. October 15.

19,101. T. W. Gimson, T. W. Gimson, W. Kent, and T. Banks. Preparing the prints used for printing potters' ware, and apparatus therefor. October 22.

20,572. A. Griffiths. Manufacture of "swan neck" fireclay pipes. October 15.

1890.

13,222. S. Sambrook. Enamelling, hardening on, and fret kilns for earthenware and china manufacturers. October 8.

13,374. J. J. Barclay and J. Meikle. Kilns for drying and burning bricks and pottery. October 22.

## IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

## APPLICATIONS.

14,775. A. Glover. An improved paving composition. September 18.

15,407. F. H. Rosher. Improvements in the process of, and apparatus for burning cements, plasters, and analogous materials. September 29.

15,678. W. A. Robinson and J. Y. Terry. Improvements in plastering compositions. Complete Specification. October 3.

15,782. J. F. Chiverall and A. Chiverall. An improvement in the manufacture and polishing and enamelling imitation stone, slate, marble, and wood. October 6.

15,784. G. A. Wright. An improved brick, block, tile, or slab for building and other purposes. Complete Specification. October 6.

15,900. L. Sterne. Improvements in the manufacture of cellular non-conducting blocks. Complete Specification. October 7.

15,940. H. J. T. Bennett. The use of peat moss and combinations therewith in the manufacture of building and paving blocks, roofing, and flooring felts, and card or mill boards. October 8.

16,231. P. Crean. An improved method of, and kiln for burning bricks. Complete Specification. October 13.

16,281. F. G. Edwards. Improvements in the use of concrete, cement, artificial stone, and similar materials for building purposes. October 13.

16,384. J. Dunn. See Class I.

16,426. E. Robbins. A new or improved manufacture of perforated or cellular constructed materials and other works, in plain monochromatic or decorative art work in "robings" for architectural, horticultural building, and for other purposes. October 15.

16,553. G. F. Redfern.—From W. Heller, Germany. Improvements relating to the treatment of gypsum for building, statuary, and other purposes. Complete Specification. October 17.

16,626. G. Brewer.—From G. Candiani, Italy. Improvements in the utilisation of the residue and waste of pyrites for the manufacture of bricks and other refractory material. October 18.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

15,737. W. T. Timewell. Manufacture of Portland cement from hard limestone. September 24.

16,327. G. B. Jerram. Paving for roads, paths, and floors. October 8.

17,623. R. E. B. Crompton and B. H. Jenkinson. Resistant coverings for battery room and laboratory floors. September 24.

1890.

3462. Baron A. von Solemacher. Manufacture of bricks, plates, and tiles. October 1.

11,443. A. Buecher. Manufacturing light bricks from gypsum, &c. October 1.

## X.—METALLURGY, MINING, Etc.

## APPLICATIONS.

14,565. S. O. Cowper-Coles. Improvements in the deposition of alloys. September 16.

14,646. C. A. Burghardt. An improvement in the manufacture of tin andterne plates. September 17.

14,658. J. F. Hall. Improvements in the manufacture of steel. September 17.

14,731. J. Broome and B. Edwards. Improvements in the means or apparatus for charging crude metal and scrap into open-hearth or other furnaces. September 18.

14,768. F. W. Martino and F. R. Martino. Certain new or improved metallic alloys. September 18.

14,781. G. G. M. Hardingham.—From M. A. Brogowski, Russia. Improvements in the manufacture of sodium and in the employment thereof for the production of aluminium, and in apparatus applicable for use in obtaining those products. September 18.

14,828. E. A. Cowper. A method of recovering fine particles of gold from pulverised mineral containing them. September 19.

14,837. C. E. Bernard. The manufacture and production of a dissolving and reducing agent and the employment of the same in coating metals with metals, or combinations with metalloids, extracting metals from their ores or combinations, and in other arts and manufactures in which dissolving or reducing action is required. Complete Specification. September 19.

14,846. W. H. Kennedy. Improvements in the method and apparatus for producing mineral wool. Complete Specification. September 19.

14,904. O. Murray.—From E. du Bois, Lukis, Mexico. A process and apparatus for extracting gold from crushed mineral containing it. September 20.

14,966. J. B. Hamay. Improvements in extracting precious metals from ores or minerals containing them, and apparatus therefor. September 22.

14,990. J. Muir. Improvements in the means or apparatus for the manufacture of iron or steel. September 23.

15,102. T. Sturgeon and T. P. C. Crampton. Improved method of casting metals in moulds. September 24.

15,110. Davies Bros. and Co., Limited, and E. A. Davies. Improvements in coating plain and corrugated metal sheets with metal or alloy, and in apparatus employed therein. September 24.

15,174. C. L. C. Bertou. A process for the recovery of the tin and the iron from waste pieces or clippings of tinned sheet or other iron or steel. September 25.

15,260. F. Braby. An improvement in the process of coating iron with other metals. September 26.

15,261. F. Braby. An improvement in the process of coating iron with other metals. September 26.

15,341. O. B. Peck. Improvements relating to the treatment of slag, and to the removal thereof from furnaces. Complete Specification. Filed September 27. Date applied for, March 3, 1890, being date of application in United States.

15,342. O. B. Peck. Improvements in apparatus for the treatment of slag. Complete Specification. Filed September 27. Date applied for, March 3, 1890, being date of application in United States.

15,343. O. B. Peck. Improvements in centrifugal apparatus for treating molten material. Complete Specification. Filed September 27. Date applied for, March 3, 1890, being date of application in United States.

15,348. O. B. Peck. Improvements relating to centrifugal apparatus for treating molten material. Complete Specification. Filed September 27. Date applied for, March 3, 1890, being date of application in United States.

15,349. O. B. Peck. Improvements relating to centrifugal apparatus for treating molten material, and to means for removing the said material from such apparatus. Complete Specification. Filed September 27. Date applied for, March 3, 1890, being date of application in United States.

15,366. L. Richards. Improved method for taking away the pigs from the casting beds of blast furnaces, and for breaking the same for sampling. September 29.

15,423. W. Wright. An improved method of reducing, blending, and welding metals, principally iron and steel. September 30.

15,433. S. Pearson and J. H. Pratt. Improvements in metallic alloys. September 30.

15,475. G. A. Decosse and V. Lespinats. An improved process of making all kinds of rolled iron. September 30.

15,506. G. H. Cannell. Improvements in the manufacture of armour plates. October 1.

15,520. H. B. Fletcher. Improvements in the process of annealing metallic castings. October 1.

15,551. A. J. Boulton.—From J. W. Bookwalter, United States. Improvements in converters. October 1.

15,582. J. Spence. Improvements in the manufacture of aluminium. October 2.

15,806. A. J. Campion and J. E. Tenison-Woods. Improvements in the treatment and reduction of metallic ores or compounds, and the recovery of metals and products therefrom. October 6.

15,830. J. T. King.—From T. S. Blair, jun., United States. Improvements in the reduction of ores. October 7.

15,833. E. Tweedy. Improvements in tempering fluid for treating steel. Complete Specification. October 7.

15,838. J. Hofmann. A process of and apparatus for making manganese bricks, and recovering sulphate of potash from "flue dust" resulting from the manufacture of ferro-manganese. October 7.

15,859. J. L. Hopper. Improvements in a process of and composition for softening and subduing refractory ores. Complete Specification. October 7.

16,060. L. Grabau. An improved method of obtaining metallic sodium. Complete Specification. October 9.

16,107. J. O. Day. Improvements in alloys and compositions for use in covering or coating surfaces of iron and steel and the surfaces of other materials, in order to prevent corrosion and fouling thereof when submerged. October 10.

16,344. R. S. Casson. Improvements in the manufacture of steel and ingot iron. October 14.

16,543. W. Pilkington. Improvements in manipulating and annealing metals. October 17.

16,545. H. H. Lake.—From O. B. Peck, United States. Improvements in apparatus for decomposing metallic salts and desulphurising ores. Complete Specification. October 17.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

12,181. E. Guillemin-Tarayre. Working, preparing, and concentrating auriferous alluvium. October 8.

15,301. W. H. Akester, W. T. Glover, and H. Edmunds. Manufacture of metals and alloys. October 1.

16,776. J. B. Alzugaray. Metallurgical dry process. September 24.

16,794. D. Dixon. Manufacture of aluminium and other metals. October 8.

17,699. C. Davy. Means for suspending and manipulating ingots or forgings. October 15.

17,878. J. Meese. Means and process for treating iron and other metals, and producing fireproof coating thereon. September 24.

17,890. A. Eyraud. Tempering, annealing, or treating castings or forgings of copper, nickel, cobalt and aluminium, or alloys. September 24.

- 17,933. D. Rylands and J. W. Horner. See Class VIII.  
 18,048. S. Pearson and J. H. Pratt. Alloys of iron and aluminium or steel and aluminium. October 1.  
 18,297. T. Haeghe and The Cape Copper Co., Lim. Process and apparatus for obtaining sulphate of copper and precious metals from copper or cupreous compounds. October 22.  
 19,333. W. Sellar. Method and apparatus for manufacture of iron or steel. October 22.  
 19,501. C. Rabache. Extraction or reduction of zinc. October 15.  
 19,865. E. P. Peyton. Cleaning sheets, &c., of wrought iron and utilising the waste products obtained, and apparatus therefor. October 15.  
 20,210. J. Hobson. Separating particles of iron or magnetic oxide from other substances. October 15.  
 20,586. J. H. Darby. Manufacture of steel or ingot iron. October 22.  
 20,677. W. L. Wise.—From J. B. Walker. Apparatus for separating or amalgamating finely-divided metalliferous material. October 15.

1890.

- 11,851. C. Rabache. Apparatus for extraction or reduction of zinc and other metals. October 15.  
 11,868. W. W. Keys. Process and furnace for treating copper and its alloys. Sept. 21.  
 12,553. I. A. F. Bang and M. C. A. Ruffin. Process and means for separation of tin from scrap and other metals. October 15.

## XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

### APPLICATIONS.

- 14,604. M. W. Dewey. Improvements relating to the heating of metals and other materials by electricity. Complete Specification. September 16.  
 14,624. A. S. Elmore. Improvements in the manufacture of metallic articles by electrolysis, and apparatus for that purpose. September 16.  
 14,693. J. P. Bayly.—From J. Silico, Mexico. Galvanic battery. September 17.  
 14,776. C. T. J. Vanlin. An improved process and means for the electro-deposition of metals. September 18.  
 15,054. S. O. Cowper-Coles. Improvements relating to the electro-deposition of metallic alloy. September 23.  
 15,114. G. C. Fricker and J. R. Bainton. Improvements in the manufacture of plates for secondary batteries, and in the construction of such batteries. September 24.  
 15,153. W. J. S. Barber-Starkey. Improvements in separators for galvanic batteries. September 25.  
 15,455. W. P. Thompson.—From C. L. Coffin, United States. Improvements in or appertaining to welding metals electrically. Complete Specification. September 30.  
 15,456. W. P. Thompson.—From C. L. Coffin, United States. Improvements in or appertaining to welding metals electrically. Complete Specification. September 30.  
 15,482. H. H. Lake.—From The Crosby Electric Co., United States. Improvements in and relating to electric batteries. Complete Specification. September 30.  
 15,640. E. Hancock and A. J. Markquand. Improvements in electric or secondary batteries. October 2.  
 16,005. W. J. S. Barber-Starkey. Improvements in separators for galvanic batteries. October 9.  
 16,054. H. G. C. Serrin. Improvements in electric batteries. October 9.  
 16,064. J. K. Pumpelly and F. Butterworth. Improvements in electrical secondary batteries. Complete Specification. October 10.

- 16,279. N. Slawianoff. Improvements in the process and apparatus for electrical casting of metals. October 13.  
 16,280. N. Slawianoff. Improved means of preventing defects, such as blow-holes and the like, in castings by electricity. October 13.  
 16,322. S. C. C. Currie. Improvements in insulating cells for electric batteries. Complete Specification. October 14.  
 16,346. S. C. C. Currie. The regulation and control of storage battery systems. Complete Specification. October 14.  
 16,399. A. J. Boulton.—From L. A. J. Joray, France. Improvements in or relating to the electro-deposition of metals. October 15.  
 16,415. M. W. Dewey. Improvements in methods of and apparatus for utilising electricity in the formation of sheet metal articles. Complete Specification. October 15.  
 16,522. G. D. Burton. Improvements in the methods of and apparatus for working metals by electricity. Complete Specification. October 17.  
 16,571. C. W. Kennedy and H. Groswith. Improvements in secondary batteries. Complete Specification. October 18.  
 16,603. C. J. Hall. Improvements in secondary batteries. October 18.

### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

- 15,963. P. Schoop. Manufacture of electrodes or plates for batteries. October 8.  
 17,205. A. S. Elmore. Obtaining zinc by electrolysis. October 8.  
 17,831. J. V. Sherrin. Electric battery carbon, and carbon compound elements. September 24.  
 17,974. H. H. Lake.—From H. Lemp. Electrical apparatus for welding, tempering, annealing, and treating metals. October 22.  
 18,350. J. H. Davies. Dynamo-electric machines. October 22.  
 18,755. A. Reckenzaun. Plates for secondary batteries. October 22.

1890.

8800. W. P. Thompson.—From I. Pearl. Electric accumulators. September 24.  
 12,628. H. F. Fowler. Welding metals by electricity. September 24.  
 13,003. D. Pepper, jun. Electrodes for primary and secondary batteries. October 15.  
 13,006. H. H. Lake.—From E. Thomson. Welding and otherwise working metals by electricity, and apparatus therefor. September 24.  
 13,013. D. Pepper, jun. Electrodes for primary and secondary batteries. October 1.  
 13,021. G. O. Rennerfelt. Electrolysis of melted haloid salts. October 15.  
 13,344. H. J. Allison.—From P. Hathaway. Galvanic batteries. October 1.  
 13,635. W. P. Thompson.—From C. L. Coffin. Electric welding. October 8.  
 13,636. W. P. Thompson.—From C. L. Coffin. Electric welding. October 8.  
 13,807. C. M. Reed. Battery compound. October 22.  
 13,905. M. W. Dewey. Welding metals by electricity. October 15.  
 13,906. M. W. Dewey. Welding and brazing metals by electricity. October 15.  
 14,604. M. W. Dewey. Heating metals by electricity. October 22.

## XII.—FATS, OILS, AND SOAP MANUFACTURE.

## APPLICATIONS.

14,697. J. B. Torres and J. D. Benjumea. Improvements in and connected with the clarification, purification, and refining of the greasy and oleaginous bodies. September 17.

15,404. W. Majert. Improvements in the manufacture of spermine. September 29.

15,817. C. Morfit. A new or improved process of refining linseed oil. October 7.

15,818. C. Morfit. Improvements in the refining of linseed oil. October 7.

16,025. W. H. Lever, J. D. Lever, and E. G. Scott. Improved plant or apparatus for extracting oil or grease from granular or pulverulent material. October 9.

16,059. C. A. O. Rosell and J. C. Pennie. Improvements in the manufacture of soap. Complete Specification. October 9.

16,579. W. Wright. An improved soap powder. October 18.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

17,870. R. Hunt. Treating crude cotton-seed oil, and oils containing resinous matter and free fatty acids, to obtain oil-soap and resinous colouring matter. October 8.

18,988. W. H. Lever, J. D. Lever, and E. G. Scott. Extracting oil or grease. October 22.

1890.

4607. C. Baker and W. E. Crane. Filtering oil. October 8.

13,985. G. P. Clark.—From D. R. S. Galbraith and T. Bell. Soap powders. October 15.

## XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

## APPLICATIONS.

14,513. T. H. Cobley and W. Elmore. Improvements in the manufacture of white lead, meaning carbonate of lead and other compounds of lead, from lead, lead ore, and other substances containing lead. September 15.

15,126. J. P. Bayley.—From C. Neal and J. M. Douglas, United States. Paint compound. September 24.

15,564. J. P. Bayley.—From J. Baulch, United States. Improved blacking for leather. October 1.

15,614. A. Melville. Improvements in solid inks for writing, copying, drawing, &c. October 2.

15,857. C. M. Higgins. Printing or stamping inks. Complete Specification. October 7.

15,858. C. M. Higgins. Printing or stamping inks. Complete Specification. October 7.

15,899. H. H. Lake.—From H. Dutrioux, Belgium. An improved varnish. October 7.

15,903. N. K. Morris. Improvements relating to the manufacture of carbonate of lead, and to apparatus therefor. October 7.

16,017. W. Dyshko. Improvements in preparing and waterproofing skins for various purposes. Complete Specification. October 9.

16,023. J. Robson. Improvements in the method of protecting iron and steel surfaces from corrosion, and in coatings for the same. October 9.

16,093. R. W. E. Maelvor and W. Smith. Improvements in the production of "white lead" or basic carbonate of lead, and apparatus therefor. October 10.

16,321. S. Banner. Improvements in compositions applicable in the manufacture of oil cloth, varnish, pigment, menstrua, cement, and the like, and method of manufacturing the same. October 14.

## COMPLETE SPECIFICATION ACCEPTED.

1889.

18,642. C. Lahusen and C. Fenerlein. Separation of "Lanoresin" or gum resin from the waste waters of wool-washing and combing mills. September 24.

## XIV.—TANNING, LEATHER, GLUE, AND SIZE.

## APPLICATION.

14,943. H. Belcher. Improvements in the treatment of skins and hides for the preparation of leather. September 22.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

18,730. W. P. Thompson.—From C. Heepe. A substitute for leather or wood, and manufacture of same. October 1.

20,403. J. Hutchings and W. N. Hutchings. Method and apparatus for extracting tannin from bark, &c. October 22.

## XV.—AGRICULTURE AND MANURES.

## COMPLETE SPECIFICATION ACCEPTED.

1889.

18,677. W. B. Kemshead. Treating sewage and producing fertilising products therefrom. October 22.

## XVI.—SUGARS, STARCHES, GUMS, Etc.

## APPLICATIONS.

14,625. W. Schückher. A process and apparatus for the manufacture of nitrated starch. Complete Specification. September 16.

15,056. M. Mackay. Improved cementitious compounds. September 23.

15,620. S. Wohle. A process for the manufacture of dextrin. October 2.

## COMPLETE SPECIFICATIONS ACCEPTED.

1890.

4754. A. J. Boulton.—From L. Bon. Apparatus for drying sugar-cane trash. October 8.

12,635. H. H. Lake.—From L. Sterberg. Sugar refining. October 8.

14,625. W. Schückher. Process and apparatus for manufacture of nitrated starch. October 22.

## XVII.—BREWING, WINES, SPIRITS, Etc.

## APPLICATIONS.

15,352. H. H. Lake.—From A. Brunn, Denmark. Improvements in and relating to the manufacture of yeast. September 27.

15,790. E. R. Budden. Improved method of and apparatus for maturing wine and like beverages. October 6.

15,881. B. Dukes.—From J. Hradil, Germany. Improvements in the method of obtaining refined spirits of wine. October 7.

16,605. C. Pontifex. Improvements in spargers. October 18.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

16,079. C. Huelser.—From N. Reif. Cooling apparatus for brewing purposes. September 24.

17,434. J. White. Manufacture of degerminated, flaked, boiled, and torrefied maize for brewing and distilling purposes, and as a prepared food, and apparatus therefor. October 22.

19,003. H. T. Brown, G. H. Morris, and E. R. Moritz. Manufacture of beer. September 24.

1890.

4108. J. McKinless. Process and apparatus for maturing spirits and liquors. October 1.

12,260. A. W. Ellis. Distillation, and apparatus therefor. October 22.

13,257. G. F. Redfern.—From G. Perschied. Manufacture of wine and apparatus therefor. October 1.

13,428. H. H. Lake.—From The Handford-Stanford Co. Apparatus for cooling and aerating wort. October 8.

# XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

## APPLICATIONS.

*A.—Chemistry of Foods.*

14,888. G. F. Meyer. Method and apparatus for extracting salt from victuals by osmose. Complete Specification. September 20.

15,854. F. T. Simson and J. Cox. Kola or caffeine or theine farinaceous and gluten food preparations. October 7.

15,981. W. Geddes. Improved malted food preparations. October 8.

16,260. J. Bowing. Improvements in the manufacture of wholemeal bread. October 13.

16,362. G. F. Redfern.—From E. Schramm and A. Chechong, Germany. Improvements relating to the preservation of bread and similar substances, and to apparatus therefor. Complete Specification. October 14.

16,508. G. W. Homer and J. Hazel. The manufacture of cream, and for the protection of cream, meat, fish, and other perishable articles from atmospheric air and other influences. October 17.

*B.—Sanitary Chemistry.*

14,858. R. Leigh. See Class C.

15,405. J. Hardwick and L. A. Newton. The treating of sewage and sewerage sludge. September 29.

*C.—Disinfectants.*

14,858. R. Leigh. Improvements in deodorising, disinfecting, and oxidising substances. September 20.

15,544. H. Peile. An improved preparation of disinfectants. October 1.

## COMPLETE SPECIFICATIONS ACCEPTED.

*A.—Chemistry of Foods.*

1889.

17,434. J. White. See Class XVII.

20,182. E. Sonstadt. Processes and apparatus for preparing an extract of tea, and utilising the by-products. October 22.

1890.

12,955. G. H. Hamrick. Manufacture and preservation of butter. October 8.

13,089. C. L. Bachelerie. Process and apparatus for preserving organic substances, especially alimentary substances. September 24.

*B.—Sanitary Chemistry.*

1889.

18,677. W. B. Kemshead. Treating sewage and sewage matters. October 22.

18,946. J. W. Calvert and J. Chaffer. Purifying the waste matters from tanneries, factories, dye-works, or other sources. October 8.

1890.

8239. W. S. West. Apparatus for treating sewage. October 8.

11,747. G. H. Haslam and P. Cornish, jun. Drying and desiccating sludge and manure. October 22.

*C.—Disinfectants.*

1889.

18,460. M. Hargreaves. Disinfectants and antiseptics, and disinfectant and antiseptic soaps. September 24.

1890.

13,046. W. P. Thompson.—From J. R. Bate and others. Preserving compounds for embalming purposes. September 24.

13,488. J. Y. Johnson.—From E. Salomon. Production of a new antiseptic. October 1.

## XIX.—PAPER, PASTEBOARD, Etc.

## APPLICATIONS.

14,586. J. L. Geddes and J. W. Johnston. Improvements in and relating to the manufacture of parchment paper. September 16.

15,432. J. Box. Improvements in paper making. September 30.

15,697. A. W. Hayles. The manufacture of paper and paper pulp from home and foreign grown marsh reeds, Danube reeds in particular. October 4.

15,776. F. Hawke. An improvement in the manufacture of copying paper. October 6.

15,868. C. R. Bonne.—From P. Hunaens, Germany. Improvements in the manufacture of celluloid articles. October 7.

15,930. C. Kellner. Improvements in lining boilers and digesters used in the manufacture of paper pulp, and for other similar purposes. October 8.

15,931. C. Kellner. Improvements in lining boilers or digesters used in the manufacture of paper pulp, and for other similar purposes. October 8.

15,995. F. V. L. Biorth. Improvements relating to apparatus for boiling wood pulp. Complete Specification. October 8.

16,408. E. Misch. Improvements in the manufacture of cellulose. October 15.

16,546. B. J. Beckmann. Improvements relating to the manufacture of paper, pasteboard, and the like, and to apparatus therefor. October 17.

## COMPLETE SPECIFICATIONS ACCEPTED.

1890.

12,139. W. Rogers. Treating paper for copying documents, and chemical compounds therefor. September 24.

12,375. W. M. Campbell-Callender. Substitute for bone or celluloid. October 1.

## XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

## APPLICATIONS.

15,687. F. Valentiner. A process or processes for the manufacture of artificial musk. Complete Specification. October 3.

16,392. R. J. B. Mills.—From G. P. Monnier and Cartier, France. A receiver for the preservation and application of chloride of ethyl. October 15.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

18,131. G. Lugin. Treatment of disulphones for medicinal purposes. October 8.

18,990. W. H. Lever, J. D. Lever, and E. G. Scott. Manufacture of tetrachloride of carbon. October 1.

## XXI.—PHOTOGRAPHIC PROCESSES AND MATERIALS.

## APPLICATIONS.

11,681. T. A. Kennedy. Improvements connected with photography. September 17.

15,991. A. McDonald. An improved preparation of chemicals adapted to the development of photographic plates and the like. September 24.

16,238. H. H. Beale. The treatment of negatives in the art of photography by means of a liquid to be called "Non-actinic." Complete Specification. October 13.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

18,517. B. Jumeaux. Compound or developer for use in photography. September 24.

19,205. J. B. Payne.—From F. C. Brinus. Process for giving a matt surface to albuminised silver paper photographs or prints. October 8.

## XXII.—EXPLOSIVES, MATCHES, Etc.

## APPLICATIONS.

11,625. W. Schüchler. See Class XVI.

14,947. E. Davies. Improvements connected with explosive and non-explosive projectiles, and in an explosive compound to be used with the explosive projectiles. September 22.

15,001. W. Norres. Safety fuse for exploding petards. September 23.

15,183. H. H. Lake.—From H. S. Maxim, United States. Improvements relating to the manufacture of explosives, and to apparatus therefor. September 30.

16,002. J. S. Taylor and S. W. Challen. Improvements in processes for producing gunpowder cake. October 9.

16,075. C. O. Lundholm and F. Lyell. Improvements in the manufacture of explosives. October 10.

16,189. H. H. Lake.—From E. T. G. Thorn, G. R. O. Westendorp, and G. L. C. Pieper, Germany. Improvements in the manufacture of explosives. October 11.

16,342. A. Lucien. Improvements in fuses and slow matches. October 11.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

11,081. C. E. Kelway. Shell and torpedo fuses. October 22.

16,629. J. S. Taylor and S. W. Challen. Plant for preparing gunpowder carbon, using gaseous or liquid fuel. September 24.

1890.

7596. E. Turpin. Preparation and application of explosive substances, and apparatus connected therewith. October 1.

8843. E. Muller. Apparatus for nitrifying cotton, cellulose, straw, &c. September 24.

11,745. H. J. Haddan.—From J. H. Voelkel. Vacuum drying apparatus for explosives. October 1.

13,085. M. Meisgen and M. Hett. Fuse or priming machine. October 15.

11,625. W. Schüchler. See Class XVI.

## XXIII.—ANALYTICAL CHEMISTRY.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

19,669. R. M. Douglas. Improvements in Sykes' hydrometer. October 8.

20,755. M. Gehre. Process and apparatus for determining the amount of water in steam. October 15.

1890.

1840. E. Chameroy. Apparatus for weighing and measuring the density of bodies. October 8.

### NOTICES.

Foreign and Colonial Members are hereby advised that the subscription of 25s. for 1891, payable on January 1st next, should be sent in good time to the Treasurer in order to ensure continuity in the receipt of the Society's Journal. Any changes of address which it is desired should appear in the new List of Members should reach the General Secretary not later than January 15th, 1891.

Post Office Orders should be made payable at the General Post Office, London, to the Honorary Treasurer, E. Rider Cook, and should be forwarded to him at Bow, unless it be desired to notify a change of address.

Members who require extra sets or back numbers of the Journal are requested to make application to the General Secretary only, to whom also changes of address should be communicated.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 41 of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. **EXRE and SPORTSWOOD**, the Society's printers and publishers, to whom all communications respecting them should be addressed.

The Secretary is instructed to negotiate for the purchase of copies of the Society's Journal for January 1883, and January, February, and April 1886. Members possessing odd copies of these numbers are particularly requested to communicate at once, stating price required, with Mr. Cresswell. The stock of all other numbers is at present sufficient for the Council's requirements.

#### LIST OF MEMBERS ELECTED, 21st NOVEMBER, 1890.

Bate, Wm., c/o National Explosives Co., Lim., Hayle, Cornwall, analytical chemist.

Boulton, Jas., Crayford Mills, Stratford, E., manufacturing chemist.

Bourcart, Dr. R., Swaisland's Print Works, Crayford, Kent, chemist.

Collinson, L. Hearn, Hearn Street, Curtain Road, E.C., soap manufacturer.

Coreoran, Bryan, 31, Mark Lane, E.C., machine maker.

Merriek, Geo. E., Merriek Thread Co., Holyoke, Mass., U.S.A., chemist.

Morrison, Geo. R., Richmond House, Plaistow, Essex, analytical chemist.

Neill, Geo. D., 26, Forsyth Street, Greenock, N.B., sugar refiner.

Robbins, Herbert, Chemical Works, Gibraltar Walk, Bethnal Green Road, E., manufacturing chemist.

Roberts, J. H. M., 50, Huskisson Street, Liverpool, brewer.

Royston, Ernest R., 15, Water Street, Liverpool, patent agent and civil engineer.

Simpson, James, 8A, Rumbold Place, Liverpool, manufacturing chemist.

Summer, Harold, Lea Hurst, Broughton Park, Manchester, technical chemist.

Warren, Jno. D., 137, High Holborn, W.C., chemical manager.

Wülffing, Dr. Chas., Abbey Mills Chemical Works, Stratford, E., analyst.

#### CHANGES OF ADDRESS.

Bowler, G. S., Journals to Crystal Palace District Gas-works, Sydenham, S.E.

Byard, A. G., Journals to Apartado 8, Bilbao, Spain.

MR. THOS. TYRER IN THE CHAIR.

### ON THE DIAZOTYPE PROCESS OF PHOTOGRAPHIC DYEING AND PRINTING.

BY A. G. GREEN, C. F. CROSS, AND E. J. BEVAN.

THE subject of this paper is a new application of a group of colour compounds discovered by one of us now more than three years ago. This group, of which the dyestuff known as "primuline" is the typical representative (A. G. Green, this Journal, 1888, 179), is characterised by the special property of dyeing cotton and other textile fabrics from an alkaline or neutral bath in such a way that the colour compound, which is a bio-amido derivative, may be diazotised upon the fibre without in any way affecting the union with the fibre substance; and the diazo derivative may then be combined, also *in situ* with various phenols and amines, to produce colouring matters exhibiting a wide range of tone and shade. These colouring matters being thus synthesised within the fibre are distinguished by considerable resistance to alkaline detergents, and when thus produced are known as "Ingrain Colours."

Primuline itself is the sodium sulphionate of a complex amido base, which is obtained by heating para-toluidine with sulphur. Its formation is preceded by that of dehydrothiotoluidine, a body which appears to be an amidobenzenyl-amidothiocresol—

and primuline-base appears to result from a further condensation of this compound and to differ from it in the same way that dehydrothiotoluidine itself differs from para-toluidine: this view is expressed in the formula for primuline proposed by Gattermann:—

(A. G. Green, J. Chem. Soc., 1889, 227; Ber. 22, 968; P. Jacobsen, Ber. 22, 330; L. Gattermann, Ber. 22, 422; W. Pfitzinger and L. Gattermann, Ber. 22, 1063). Homologues of primuline closely similar to it in properties are similarly obtained from meta-xyldine and pseudo-cumidine.

The special photographic application of this group of colouring matters, which we are about to describe, depends in the first instance upon the sensitiveness to light of their diazo derivatives, this sensitiveness being increased in a very remarkable degree by combination with the complex colloids which constitute the textile fibres. Under these circumstances the diazo derivatives are completely decomposed by light, the product of decomposition being inert substances incapable of combining with amines or phenols. This fact, taken in conjunction with the special affinity of these bodies for textile fibres, give all the conditions necessary for the production of photographic pictures; the actual photographic agent being the diazo-primuline, in which form the image is produced, and the development of the image consisting in its conversion into any of the colouring matters obtainable by combination with phenols and amines. It is obvious that the pictures so produced are positives. As an illustration of the process we may take the production of coloured photographic designs upon cotton cloth.

The material is first dyed with primuline from a hot bath, to which some common salt may be added, by which it acquires a primrose-yellow colour. It is then washed and diazotised by being immersed for half a minute in a cold solution of sodium nitrite ( $\frac{1}{4}$  per cent.) which has been sharply acidified with hydrochloric, sulphuric, or other acid. The material is now washed in cold water and stretched out on a level white surface, and exposed to light beneath the object of which it is required to produce a positive reproduction. We may, of course, print from ordinary photographic positives, or from natural objects, or from any painted, printed, or photographed design or picture upon any sufficiently transparent material. Either sunlight or an artificial light of sufficient intensity may be employed, the time of exposure, of course, varying with the intensity of the light: in printing by daylight, the exposure varies from half a minute in bright sunshine to nearly half an hour in very dull weather.

When the decomposition of the diazo compound in the "high lights" of the picture is complete, which can easily be ascertained by means of a test slip exposed simultaneously, and touched with a solution of  $\beta$ -naphthol at intervals, these portions will be found to have changed from an orange to a pale yellow. The material is now either passed into the developing bath at once, or is kept in the dark until it is convenient to develop the image. The developing bath consists of a weak solution (about  $\frac{1}{4}$  per cent.) of a suitable phenol or amine, depending upon the colour in which it is required to produce the design. The following phenols and amines amongst others have been found to give good results:—

*For red.*—An alkaline solution of  $\beta$ -naphthol.

*For maroon.*—An alkaline solution of  $\beta$ -naphthol-disulphonic acid.

*For yellow.*—An alkaline solution of phenol.

*For orange.*—An alkaline solution of resorcin.

*For brown.*—A slightly alkaline solution of pyrogallol or a solution of phenylenediamine hydrochloride.

*For purple.*—A solution of  $\alpha$ -naphthylamine hydrochloride.

*For blue.*—A slightly acid solution of amido- $\beta$ -naphthol- $\beta$ -sulphonate of sodium (eikonogen or anglol).

If it is required to produce the design in two or more colours, the respective developers, suitably thickened with starch if necessary, may be applied locally by means of a brush or pad. After development, which with cotton is complete in less than a minute, the material is washed, and the picture requires no further fixing. In the case of the purple and blue developers it is necessary to wash the material finally in a very weak solution of tartaric acid.

Velveteen, linen, silk, wool, and other fabrics are treated in the same way, except that in the case of wool and silk a longer exposure to light is necessary, and the immersion in the nitrite and developing baths must also be more prolonged. The maroon and blue developers are not suitable for silk and wool.

Architectural and engineering drawings can be copied with clearness and accuracy upon paper or calico which has been dyed with primuline, diazotised, and dried. The diazo paper for this purpose can be kept in the dark for some time without undergoing decomposition. The copy is developed by brushing over the surface a solution of  $\beta$ -naphthol or  $\alpha$ -naphthylamine.

Transparent photographic pictures can be produced upon glass by coating it with a film of gelatin containing primuline, then diazotising with nitrous acid, printing, say from a carbon or silver positive, and developing as before. In all the above applications the primuline may be replaced by its higher homologues already mentioned; and for producing designs upon silk, dehydrothiotoluidine sulphonic acid and its homologues may be employed, which are equally sensitive to light.

Such is the process which we have devised and tested for a very considerable range of applications.

In point of simplicity, it certainly leaves nothing to be desired; and in regard to cost, for both material and time, offers considerable advantages over any known process of photographic printing.

It is hardly, perhaps, the place or time to enlarge upon the technical or aesthetic merits of the process. These it will have to vindicate by results, and in competition in a field where a very high order of perfection obtains.

We confine ourselves rather to that aspect of our subject from which it is to be regarded as a contribution to the progress of chemical science.

So far as we are aware, it is the first process which has been devised in which derivatives of the aromatic hydrocarbons are employed for the production of a *positive* image capable of development in colour. In this respect it differs altogether from that recently published by A. Feer. This process depends upon the sensitiveness to light of the diazo-sulphonates, produced by the action of the inorganic sulphites upon diazo compounds.

The action of the light consists in a dissociation of the diazo-sulphonate, the diazo group being set free. If, therefore, a mixture of such a compound with a phenol capable of reacting with the diazo derivative (to form a colouring matter) be exposed to light, synthetic union takes place between the diazo group and the phenol in proportion as the former is set free, and if, therefore, the exposure takes place as in the ordinary process of photographic printing, a coloured image or picture results. The product of the union being a colouring matter sufficiently insoluble to resist washing, the unaltered mixture of diazo-sulphonate and phenol being, on the other hand, freely soluble, the print is finally fixed by copious washing. By this method it is obvious that a *negative* is produced, and is fully *developed* in and by the printing process, whereas in the primuline process, the light acting as a destructive, not constructive agent, the exactly opposite result is produced, and the development of the image is a subsequent operation.

It is, perhaps, scarcely necessary to point out that *development* has not the same significance when used in relation to this process as in the ordinary methods of printing, e.g., with silver compounds. In the latter case, the picture may, in a sense, be said to be *evolved* by the developer, the intensity of the image being, to a certain extent, under the control of the operator; in the primuline process, on the other hand, the development is a strictly quantitative effect, determined by the amount of the diazo primuline on each portion of the printed surface. The intensity of a print is in this case simply determined by the weight of primuline per unit of surface. It is to be noted, however, that the diazotype process does also afford a means of intensifying the print. In cases when a developer is used, e.g.,  $\alpha$ -naphthylamine or phenylenediamine, which yields a colouring matter with a free amino group, the

product may be re-diazotised, and the diazo derivative again combined with an amine or phenol, thus obtaining a diazo compound of darker shade.

In comparing the diazotype process with the ordinary methods of photographic printing, the next question which arises is as to the mode of action of the light, considered (a) physically and (b) chemically.

(a) The rays which decompose the diazotised primuline are different in order and distribution from those which attack silver bromide. Photographs of the spectrum by the two processes taken side by side show, in the case of the diazo print, a sensible shifting of the area of maximum effect towards the red, and the diminution of activity is a very gradual one, probably extending beyond the visual limit of the red. We have, as might be expected, experienced some difficulty in carrying out this part of our researches, and we must content ourselves, pending their completion, with this very general indication of their results.

(b.) In regard to the chemical changes which accompany the "discharge" of the diazo primuline on exposure, the main point which we have established is that the diazo group ( $-N=N-$ ) is completely eliminated as free nitrogen. The evolution of gas is easily observed by allowing the light to act upon the sensitive surface submerged in water; and quantitative observations showed that the volume of gas evolved was in accordance with the requirements of the formula, on the hypothesis that the diazo nitrogen was split off. This result is confirmed by the observation that the product of decomposition is not reconverted into primuline nor into the corresponding hydrazine by treatment with sodium hyposulphite ("hyposulphite") or with stannous chloride. As to the constitution of the product, it remains undecided whether it is the phenol corresponding to the diazo primuline, the decomposition being analogous to that of diazobenzene by heat, or whether the primuline residue enters the molecule of the cellulose or other medium which carries it. The latter hypothesis is supported by the fact already mentioned that the molecular union of the diazo-primuline with the colloid medium is a necessary condition of the reaction, for the free diazo primuline when exposed to light in a thin film is either not decomposed at all or only after very prolonged exposure. The investigation of these problems is rendered very difficult by the complex character of the products, and again we must content ourselves, pending its completion, with a general indication of the results.

We hope shortly to be able to publish results which will more completely elucidate the mechanism of the reactions upon which the process depends.

In conclusion, we wish to express our indebtedness to Professor Norman Lockyer, F.R.S., for affording us valuable aid in the work of photographing the spectrum, and to the Autotype Company, through their manager, Mr. W. S. Bird, for the loan of some of their beautiful positives for printing specimens in illustration of the process.

#### DISCUSSION.

The CHAIRMAN said that one of the difficulties under which authors laboured who had many experiments to show, and who were thoughtful about them, was that they could scarcely think about their manuscript, it was a great advantage therefore that the members of the Society could rely on being able to read the paper for themselves in the Journal. In the present instance, however, it would be impossible for them to forget when doing so the more than eloquent appeals to their imagination and conviction which had been carried to their minds by the experiments which they had seen. The fabrics which had been dyed and finished were sufficient evidence that the new process of photography was one which would have very important effects on the future, at least of the textile industry. In decorative arts the process would have a very wide field of application, and he could not but congratulate the authors upon having applied their invention so successfully to the specimens before them. One could not but be reminded by this paper of the classical researches of Greville Williams on the cyanines, and it was a matter of scientific interest—which perhaps Mr. Green might see fit to refer to in his

reply upon the discussion—to determine the position which the diazotype process occupied in relation to those researches and to the ordinary processes of photography. Of course the two things were not on the same level; but there was a possible practical development of the process which they would do well not to overlook. Those who were interested in the duplication of machine drawing would have recognised in the admirable specimen shown, ample proof that the new process was applicable to that purpose in an equal degree to the well known ferrotype process.

Dr. R. BOURCAST said that he admired the process described by the authors exceedingly; it was very interesting, quite novel, and would, he thought, prove to be very useful. While in Mulhouse last autumn, his attention had been drawn to a process which appeared to him to be the reverse of that described by Mr. Green, the printed fabrics being quite devoid of colour when printed by night, and the colours being developed in a few seconds on exposing them to daylight. He had looked into the Journal of the Society of Mulhouse hoping to find a full description of that process, but without success. In September 1889, however, a note appeared in which the materials employed were described as diazosulphonic bases upon which phenols acted. It seemed that the fabric was prepared with phenols, and was then printed with a mixture of the base with nitrite of soda, hydrochloric acid and ice. But the fabric was colourless until exposed to the light. Paper printed in this way, when placed in the camera of a photographic apparatus, gave very sharp photos. The process now before them was entirely different. In that case they had a colouring matter, primuline, which when combined with phenols was capable of giving an immense variety of colours. The base, primuline, before combination with the phenols, was yellow, and its colour would fade very quickly in light; but it appeared to be protected from the destroying action of the light by the phenols. There were some other colouring matters which also faded very quickly on exposure to light. Some eosine exposed by him to sun rays was completely destroyed in 110 minutes, and in 3½ minutes a distinct decolourising effect was produced by the sun. He had heard of other colouring matters which were still more fugitive, quinoline blue, for instance. In the case of primuline, however, although it was a colour which faded in the light, it could, as he had said, be protected from fading quickly away through the light, by combination with phenols into diazo compounds, and it then became quite as fast as most aniline colours of the best kind; he even had noticed that azo colours were much less sensitive to the action of light than aniline or phenol colours. He had had experience of another substance which had the same properties. It was a compound used for obtaining positive copies of designs for engineering purposes. A sheet of white paper was painted with a mixture of perchloride of iron and tartaric acid. It was allowed to dry in darkness, and on then being exposed to the light with the Chinese ink drawing upon it, the colour faded except where it was protected by the ink. The design thus produced was then fixed by immersing the paper in a solution of gallic acid. He had used the process for producing drawings of such delicate objects as the wings of insects, and had found it to answer admirably. In conclusion, it appeared to him that primuline might be very usefully employed as a standard for measuring the amount of light obtainable in a room. For example, if an architect had to build a workshop in which a certain amount of light was required, by means of this primuline he might obtain a photograph which would prove whether or not he had satisfied the conditions required of him. In fact he had seldom listened to a paper of so novel and interesting a character, and so well given.

Dr. C. R. ALDER WRIGHT had listened with the greatest interest to about two-thirds of the valuable paper just read, and deeply regretted that he had missed the first portion of it. Perhaps, in consequence of that omission, there were one or two points which led him to inquire whether the last speaker was right in supposing that it was the primuline itself which was acted upon by light, or whether it was not the diazo compound thereof. He had gathered that it was

the diazotised primuline which was affected by light, and one proof of that would, he thought, have been afforded by the experiment, which the lantern did not allow them to see, in which the nitrogen was to be eliminated under the influence of light. As regarded the technical uses of the process, there could be no doubt that there existed a large number of ways in which such matters could be successfully employed. Notwithstanding which, the question occurred to him whether in this country the amount of actinic rays available during the year was sufficiently large to enable the process to compete with more sunny climates in an industry which required that particular sort of mechanism to bring about the necessary reactions. If some cheap form of chemical could be found which would produce the necessary alteration of the diazo compound, that might enable us to compete with other nations more favoured in the matter of sunlight. The process would then become more or less analogous to the old style of discharge process, the operations of which were effected by chemical reagents rather than by light. With regard to the use of inorganic substances for bringing about such reactions, he would point out that iron was not the only metal available. Several other metals were known—more expensive, perhaps—which, from experiments made with them, appeared to present at least the possibility of useful application in that direction. Some of the compounds of the rarer metals—for instance, tungsten, molybdenum, perhaps even vanadium—were capable of being acted upon by light, and when subjected to the action of developers of an organic character, were capable of giving prints somewhat similar to those given by the ferrotype process. Some experiments in that direction were at present being made in his own laboratory by Dr. Leon, who was unfortunately prevented by illness from attending that meeting and giving the Society some information on the subject so far as he had gone into it. The peculiarity that struck him most in this peculiar method of dyeing, from the chemical point of view, consisted in the complexity of the fundamental substance, primuline, if the gigantic formula written on the blackboard was to be regarded as representing its constitution. When the body became diazotised, it was the  $\text{NH}_2$  group which was affected, and not the other nitrogen atoms. He would like to ask, therefore, whether the authors possessed any information as to the nature of the chemical change which light produced on the diazotised body. He understood that nitrogen was evolved, and that suggested that the compound was analogous to the earlier-discovered diazotised bodies, which had not infrequently been the source of very uncomfortable explosions. The late Dr. Peter Griess had, he believed, been the victim of several accidents whilst investigating the properties of that class of compounds. He would like to ask, therefore, whether, if a large quantity of the material was being acted on, the evolution of nitrogen was likely to be so considerable and so sudden as to generate such a pressure as would lead to that violent expansion which in popular language was called an explosion.

Mr. JOHN SPILLER said that when, about two years ago, Mr. Green gave an account of his then newly-discovered base, primuline, he had but an imperfect idea of the alterable nature of that substance when exposed to light in a diazotised condition. That property had hitherto been regarded as an obstacle to the use of the substance as a colouring matter. But in the hands of Mr. Green it had become one of its prime qualifications, constituting it a photographic agent by the use of which they could obtain the effects of light exposure which had been exhibited to them that evening. He was especially interested in the production of the blue print which was before them, as it seemed to him that the capability of producing such prints would enable the process to compete directly with the ferro-prussiate process which was so much in vogue as a means of reproducing engineers' mechanical drawings. The use of Mr. Green's new material would certainly run that process very closely; and if the results obtained by it were as permanent as Mr. Green's experiments (and in a smaller measure his own) gave them every reason to expect, they would have not only a radically new process, but one possessing advantages which could not be overlooked in comparing it with other methods now in use.

Mr. T. BOLAS wished to point out that from a photographer's point of view one of the first questions that would arise with regard to the new process would be its permanency. He was formerly employed in a carbon printing works, and had had a great deal to do with the testing of pigments for use in the so-called carbon printing process. No doubt the members were aware that ordinary carbon prints were produced from a mixture of carbon as a base, toned down by certain pigments (generally indigo and alizarine lake containing an excess of iron or alumina). The ordinary method of testing a pigment for carbon printing consisted in exposing a print prepared from it in a high place and inclined a little to the south, so as to get the full benefit of the light. If at the end of so short a time as six months of summer light the lighter tones showed any signs of fading, the mixture was at once rejected. Mr. Spiller seemed to him to speak somewhat doubtfully of these prints in saying, if the results were as permanent as Mr. Green's experiments, and in a smaller measure his own, gave them reason to expect. With a view of testing their permanency, he had prepared a few prints by means of the primuline methods (including Feer's) some weeks ago, and had exposed them in a high place, intending to leave them there till the summer end of the season. But he happened to look at them two days after placing them out to the light, and was surprised to find indications of fading in the lighter tones. It would be interesting to know how far the prints before the meeting had been fairly tested for light, because from the photographer's point of view, a print which would fade by six months' exposure to summer light would be out of the question for practical use. When the matter was under discussion at a meeting of the Photographic Society, Mr. Spiller mentioned some tests which he had made, but he did not understand him to state what length of exposure he had given. It would be interesting to have some information on that point from him; and Mr. Green might possibly be able to add something also, though he feared that the process had not been known sufficiently long for thorough tests to be made. In the declining light of autumn, a few months' exposure was hardly equivalent to a few weeks in the early part of the summer. He had with him two prints that had been exposed for a week, one developed with  $\alpha$ -naphthylamine, and the other with orcin, which gives a colour very like that of resorcin. It would be seen that where the prints were not covered with paper the intensity had been very much reduced—so much that in the case of half-tone the lighter tints would be entirely gone.

Mr. A. H. ALLEN wished to know whether the diazotised primuline was insoluble in water, and the product of its decomposition by light soluble. If it were soluble in water, Mr. Green ought to be able to dissolve it out in a pure form, sufficiently pure, at any rate, to enable him to ascertain its nature. He would suggest that that should be done, if he was right in his supposition.

Mr. D. HOWARD wished to call the attention of the authors to a point which might be worth their consideration. He would suggest that they should ascertain how far the photographic power of their substance was isochromatic. If it were a true isochromatic agent, provided one could get a negative which would give even one print, it would be valuable, because it would be possible to reproduce further copies from that with other more permanent agents which did not themselves possess the advantage of being isochromatic. The progress already made in isochromatic photography encouraged one to follow up any possible lead in that direction.

Mr. JOHN SPILLER remarked that in his previous comments on the process before the meeting he had spoken only of the researches of Mr. Green, accidentally overlooking for the moment that Messrs. Cross and Bevan were associated with him in the matter. He should of course have spoken of the new method as the work of Messrs. Cross, Bevan, and Green.

Mr. W. E. FRIESE-GREEN said that since the authors had brought their discovery before the Photographic Society,

he had made some experiments on it, one of the results of which was to prove that the process was more sensitive if nitrite of silver were used instead of nitrite of sodium. With regard to spectrum work, he had found that the green band was acted on more than any other. He regarded the process as extremely valuable, but would like to see an improvement made in it in the direction of substituting a white background for the present yellow one. If that could be done the application of the process might be extended to the illustration of books and papers.

Mr. A. G. GREEN, in reply to the Chairman's inquiry as to whether there was any similarity in the constitution of the two bodies cyanine and primuline, said that there was very little resemblance. In a sense, of course, there was a connexion, cyanine being a quinoline derivative and primuline being distantly related to the quinoline series. He did not think that the sensitiveness to light was due to the primuline radicle itself, but rather that the primuline provided the means of fixing an amido compound on animal or vegetable fibres, and in that way enabled the diazo compound to become sensitive. His experience was that when so applied, or when in conjunction with gelatin, nearly all the diazo compounds were sensitive to light, however little they might possess that property when separate from the fibre or the gelatin. If one took some primuline, and smeared it over paper it would take hours to decompose completely; whereas if the same paper were dyed with it it could be decomposed by sunshine in one or two minutes. He was well acquainted with the process referred to by Dr. Bourcart. It was known as Feer's process, and was applicable to any diazo compound. But it gave a totally different reaction to that which he had described, because it was a constructive process, the azo colour being formed by the light, and not decomposed by the light as in the case of primuline. Dr. Wright had inquired whether it was the diazo compound of primuline or the primuline itself which was decomposed by light. He was quite right in supposing that it was the diazo compound which was affected. Primuline itself would stand exposure to sunlight, certainly for several days. It did change slightly by exposure to light, but so did most colouring matters. He had omitted to say that for practical purposes the electric light would have to be used, since they could not depend on daylight for continuous working. They had tried printing by it with considerable success, and with proper arrangements it would be much more convenient to use it, as the time required for exposure varied considerably. With regard to instability of diazo primuline to heat, the diazo compounds of high molecular weight were not very unstable, even when existing separately, and certainly not when in a very diffused condition on the fibre. The diazo compound of primuline could be boiled in water for an hour with scarcely any decomposition, whereas diazobenzene would decompose in water which was scarcely warm. Mr. Bolas had inquired about the stability of the compound to light. That was a point upon which they could not say much at present, for the simple reason that they had not had time to thoroughly test it. He hardly expected that diazo prints would be equal to carbon prints in that respect. At the same time he thought that the degree of stability would vary under different conditions, and that prints would be much faster to light on gelatin films than on cotton. The material printed upon was concerned in the reaction and greatly affected the results. It also made a difference to the stability whether the compound was or was not completely diazotised and developed. If the development were weak the colour would be unstable. In reply to Mr. Allen's inquiry about solubility, he would say that the ground substance was perfectly insoluble and could not be removed. They had tried to remove it so as to get a white ground, but had been unsuccessful so far. Though the yellow back was in many respects artistic, it would be useful to be able to have a white ground; and on silk they could nearly obtain it by using the sulphonic acid of dehydrothiotoindine, the diazo compound then leaving a nearly colourless background when decomposed by light. They had not tried any experiments in using primuline for obtaining isochromatic plates; but he believed that such experiments were being

made by one or two gentlemen. He was much interested by Mr. Friese-Green's statement that silver nitrite gave a more stable product than sodium nitrite. He would not have expected that the nitrite would make any difference, as an acid was present. But the reaction had been so little studied as yet that it was quite possible that many things would turn up with respect to it of which they were ignorant at present.

## THE PERMANENCY OF CREOSOTING AGENTS.

BY FRANKLIN S. CLARK, PH.D.

IN America, the processes of preserving wood have, up to the present time, been confined more especially to the treatment of timber exposed to the ravages of sea-worms.

The impregnation of railroad ties, such an important part of the work in European countries, is here a matter of secondary importance, since the easy access which American railroad companies have hitherto had to inexpensive wood has led to the replacement of ties in preference to the expensive methods incurred by an artificial treatment.

The present indications are, however, that many of the roads over whose lines the price of the timber has been enhanced by cutting, will gradually resort to some method of preservation.

The selection of process and principle in the American treatment is therefore primarily directed to the conditions necessary to protect timber from the attacks of sea-worms, so destructive to all wooden structures exposed in the waters of the South Atlantic, Gulf and Pacific coasts of the United States, as well as the sea-coasts farther south.

Experience has shown that wood that has been rendered invulnerable against the ordinary processes of decay will, in these exposures, fail, and that only by combining the most efficient process and preserving agent may the wood be expected to remain uninjured.

Notwithstanding the low price of timber and the comparatively high cost of the prepared material, American engineers have been compelled to resort to some methods of preserving sea structures exposed to the attacks of the teredo and limnoria.

Examinations made upon the various agents which had found favour in Europe for preserving wood has shown that the greater number of these are not adapted for the treatment of wood to be exposed in sea-waters.

Thus of the four more prominent agents of wood treatment literature, copper sulphate, zinc chloride, mercuric chloride, and dead oil, the latter alone has been extensively adopted in American practice.

Of the objections which have been offered against the metallic salts, none is so vital as that founded upon their ready solubility in water, the insolubility of the agent now being recognised as, perhaps, of more importance than the antiseptic power of the body itself. Consistent with this view the metallic salts are no longer used for the preservation of wood used in salt water, but in their place we find the oily products resulting from the destructive distillation of bodies capable of yielding creosote.

A reference may here be made to the ill-appropriated name creosote, as applied to the heavy fraction of coal tar. It has been stated that true creosote has never been used for the treatment of wood antiseptically. As will be seen from this communication, the oily products resulting from the destructive distillation of wood are extensively used in America for creosoting work, and as the oil is used and sold under the name wood creosote oil, or creosote oil, there is a possibility of rendering the name ambiguous in trade as well as in technical literature.

Fortunately, the heavy oil or creosote oil of the English works is in America more commonly called dead oil. Since chemistry has conferred the name creosote upon certain constituents of wood tar, it is but rational that this name should be applied to the oil containing the true creosote.

Wood creosote oil is the principal competitor of the dead oil of coal tar in the United States.

In Dr. Lunge's "Distillation of Coal Tar," we read, "For preserving wood, coal tar was recommended as early as 1799 by Le Bon, but for this purpose it is inferior to wood tar, which even now is exclusively used in shipbuilding. Wood tar penetrates more deeply into the pores of the wood, covers it with a coherent coat, and the preservative action of its phenols is assisted by its paraffin."

Dr. Ch. Heinzerling, while admitting the high price of the tar from wood, declares it to be uniformly the best tar for impregnating wood. (Die Conservirung des Holzes.)

The mechanical difficulties attending the use of wood tar in the creosoting cylinder have precluded its use on a large scale, but these difficulties are not encountered when, instead of the crude tar, we used the wood creosote oil resulting from the dry distillation of the long-leaved pine, *Pinus palustris*, of the South Atlantic and Gulf States.

A detailed description of the manufacture of this oil appeared in the School of Mines Quarterly for January 1888 (this Journal, 1888, 197), and only a general description will be necessary here.

The basis of the operations is the long-leaved pine now much used for constructive purposes in engineering, but more familiarly known as the source of the turpentine of commerce.

The tree as it stands in the forest is first tapped for turpentine; this operation extending over several years, or until no considerable quantity of the volatile oil is obtained, and the blazed surface is covered with rosin. Such trees are then abandoned by the turpentine producer, and as they stand in the forest become year by year more resinous. These trees are now in a condition suitable for the retorting process, and after felling and cording the wood is drawn to the river bank and by flats taken to the cities where the creosoting works are located.

At the present time there are in the United States three works at which timber is impregnated with wood creosote oil, but otherwise by the ordinary process of heat, vacuum, and pressure. These works, situated at Wilmington, N.C., Charleston, S.C., and Ferdinand, Flo., carry on the process of oil manufacture as well as treating timber. Work is done with dead oil if the contract calls for it.

The practice at the Wilmington works is representative of the industry as carried on in the United States and will be given here in brief.

The oil plant consists of 20 retorts having a charging capacity of four cords each. A cord is a pile of wood 4 ft. broad, 4 ft. high, and 8 ft. long. A bushel fills 1.2836 cub. ft. The apparatus may be of any of the ordinary types used by the wood distiller.

The products are collected in two portions, a light oil (and water) having a sp. gr. 0.875—0.975, and a heavier oil (with pyroligneous acid) or second running having a sp. gr. of 0.975—1.045. The latter is separated (by gravity) from the wood acid and held for further treatment. The light oil, after the separation of the water, is subjected to successive distillations with caustic soda solution, there resulting thereby a colourless hydrocarbon, which (under the name "palustrine") is used as a substitute for spirits of turpentine, and a residue of soda creosote which is added to the second running mentioned above.

The addition of the soda creosote to the heavier product of the retorts effects the neutralisation of the acetic acid contained in the latter to an important extent, and enriches the oil by the addition of creosote and other heavy bodies. Much objection has been urged against dead oil on account of the corrosive action of its phenols upon the lead sheathing of electric cables in cases where the conduits have been creosoted.

The wood creosote oil has the same effect if the acetic acid is not neutralised.

After the soda creosote treatment the oil is allowed to settle and the acetate of soda drawn off. The oil is now washed with water to remove any soluble matter, and after settling forms the wood creosote oil, which is the subject of this communication.

The acid resulting from the distillation is utilised in the manufacture of methylic alcohol and pyrolignite of iron.

The charcoal is used for fuel under the retorts, and the wood gas has found application in heating the steam boilers of the refining works. The charcoal is of too inferior quality to be used in smelting.

By utilising the by-products as described, the wood creosote oil may be made at a lower price than the dead oil is sold in the United States.

Analyses of the soda creosote, second running, and wood creosote oil gave the following percentages, by weight, of the different constituents at 50° F.:—

	Soda Creosote.	Second Running.	Wood Creosote Oil.
Water .....	4.05	3.57	2.79
Indifferent oil (distilling under 534° F.) .....	1.17	14.96	13.46
Crude creosote .....	19.38	14.42	17.00
Heavy oil (distilling above 534° F.) .....	42.42	22.35	26.55
Wax (paraffin resin) .....	14.88	27.61	26.55
Coke .....	9.24	6.87	5.78
Loss .....	8.56	10.23	8.75
	100.00	100.00	100.00

The second running examined was an average sample taken from 16 cords of wood in ordinary operation; the soda creosote and wood creosote oil were taken from the working tanks of the creosoting works. The analysis was made by distilling the oils to dryness in a cylindrical wrought-iron still (substantially the same as that represented in Dr. Lunge's "Distillation of Coal Tar") having a charging capacity of 9 gallons (231 cubic inches).

Temperatures were taken at every per cent. by volume of the distillate.

The indifferent oil is the light oil which remains after treating the fraction distilling under 534° F. with a 1.21 solution of caustic soda. It is unaffected by the latter. The crude creosote was separated by practically the same process as followed by Sir Frederick Abel with dead oil, the fractions below and above 534° F. both being treated with the caustic soda solution.

The loss is mostly due to a non-condensable gas, and in this respect the distillation differs markedly from that of dead oil of coal tar, the loss in the latter case being comparatively small. The loss in the wood creosote oil is due to the high temperature necessary to bring the heavy fractions over from the still, some of the oils being decomposed at the temperature of distillation.

Some idea of the uniformity of wood creosote oil may be obtained from oil produced under different conditions from that given above. The oil in question was obtained from South Carolina wood as distilled in a one-cord retort at the Charleston works and, not having received any addition of soda creosote, compared to the second running of the North Carolina oil. Determinations were made in a 50-gallon still, and the following results were obtained from an average of many analyses:—

	Per Cent. by Weight.
Water .....	3.97
Indifferent oil .....	15.53
Crude creosote .....	14.32
Heavy oil and wax .....	42.76
Coke .....	6.99
Loss .....	16.43
	100.00

The distillates at 600° F. were 45.48 and 37.40 per cent. by volume respectively. The above results show a considerable loss of heavy oil and wax (due probably to the still treatment), but otherwise the results are close when we

consider the different conditions under which the tests were made and the usual inaccuracies connected with this kind of analysis.

The creosoting plant proper, wherein the wood creosote oil described is used, does not differ essentially from the works where dead oil is exclusively used.

There are four creosoting cylinders, 66, 75, 88, and 100 feet long, the diameter of each being six feet. The process consists in submitting the wood to heat, vacuum, and oil pressure, each one of these steps requiring the most thorough execution, especially when green wood is under treatment. The first operation is but an artificial seasoning effected by passing superheated steam through closed pipes in the cylinder and thus drying the wood by a gradually applied radiant heat.

Simultaneous with the drying operation the vacuum pump is put on and kept at 26 inches of mercury until the wood is considered to be in a condition favourable to a thorough impregnation with oil.

The heat and vacuum process varies with the kind and condition of the wood to be treated, but is seldom kept up for a greater period than 24 hours. In this operation the albuminous constituents of the wood are coagulated and the moisture removed, partly in the vaporous and partly in the liquid condition. When the drying process is complete, the oil, heated to 120° F., is pumped into the cylinder, the vacuum pump running until the cylinder is charged to the finish. The pressure pump is now used to fill the remaining space and exert the pressure necessary for a complete impregnation.

One of the most important advantages of the creosoting process is in rendering the less durable sap woods more permanent, when exposed to deteriorating influences, than the best heart wood. The harder grades of wood need the treatment less and, in fact, are less perfectly treated. Practically the oil cannot be injected into heart wood.

The more sap wood in a piece of timber the better suited is the latter for creosoting purposes and the more likely to resist the sea-worms. The pecuniary saving resulting from the treatment of sap wood is well presented in Dr. Heinzerling's "Die Conservirung des Holzes." The wood more generally treated in the Southern States for piles to be used in salt water is the *Pinus taeda* or *loblolly* of the mills. A loblolly pile, 9 in. x 16 in. x 33 in. recently creosoted with dead oil, showed oil  $5\frac{1}{2}$  in. deep at the mid-section of the stick. A piece of good heart wood similar to the above would probably show oil not more than one-eighth of an inch. In considering the properties of the oils used in creosoting work it is well to examine the views now held regarding creosote oils. As already mentioned, antiseptic salts first tried, failed with timber exposed to sea-water. The cause of the failure is attributed to the solubility of the salts or their albuminoid compounds.

Dead oil soon replaced them and on account of its comparative insolubility has found extended application in marine work.

The use of dead oil, and especially the heavier grades of this oil, has been an acknowledgment, on the part of engineers, of the efficacy of the mechanical as distinguished from the chemical or physiological properties of wood-preserving agents.

The insoluble and non-volatile constituents of the oils exert a physical action in excluding air and water, and in retaining mechanically the bodies which would otherwise be dissolved. The principle here involved is exerting a strong influence upon the selection of dead oils at the present time, the heavy (non-volatile) insoluble oils meeting with the most favour.

The quantity of oil lost by volatility from creosoted timber is much greater than is commonly supposed, and since the oil which has been lost can be of no service to the timber when used, the question of evaporation of oil from treated timber becomes a matter of commercial importance.

The cost of creosoted timber depends, primarily, upon the quantity of oil put into the wood, and the value of the treated material depends upon the quantity of the valuable constituents which remain after the timber has been subjected to the usual conditions of volatility and solubility.

The element of volatility affects not only all treated timber used on land but also that which is destined for immersion in salt water.

Timber after coming from the cylinders is left exposed at the works, on the vessel or at the place where it is to be used. After it has been put down, the portion between high and low water is exposed to conditions favourable to the evaporation of the more volatile constituents.

The tests made on the volatility of the wood creosote oil and dead oil were carried on throughout by treating samples of *Pinus terda* which had been deprived of their moisture by heating in a (steam) dry kiln at a temperature of 180° F. for five days.

The first determination of loss by evaporation was made by a heated immersion of the wood samples in the respective oils, two samples of wood being used for each oil and all of them having been cut from the same stick so as to insure uniformity.

The four oils used were as follows:—

(1.) Wood creosote oil from working tank and a good average of the oil used in practice.

(2.) Dead oil from one of the New York dead oil companies. Represented as a heavy dead oil with a large percentage of naphthalene, and an average representing 500 barrel quantities.

(3.) Dead oil from the same company as (2.). Represented as a light oil with a small percentage of naphthalene. An average like (2.).

(4.) Dead oil from another New York company. Represented as an average as sold for creosoting work.

The above samples of dead oil, containing about 50 galls. each, were heated by means of a tight steam coil, and after melting and mixing to secure uniformity they were analysed under identically the same conditions as the wood creosote oil.

The percentages by weight at 50° F. were as follows:—

Number of sample.....	1.	2.	3.	4.
Water mechanically contained..	2.08	0.59	0.24	0.42
Water of decomposition.....	0.71	..	..	..
Indifferent oil .....	13.16	21.62	42.47	48.59
Crude creosote.....	17.00	..	..	..
Tar acids .....	..	9.72	15.34	16.63
Heavy oil.....	26.55	..	..	..
Wax (paraffin resin) .....	25.97	..	..	..
Solid bodies (naphthalene, &c.) .	..	67.50	40.23	27.77
Coke.....	5.78	0.28	1.49	6.42
Loss.....	8.75	0.29	0.23	0.26
	100.00	100.00	100.00	100.00

And by volume:

Distillate under 534° F. ....	26.00	77.00	61.00	78.00
Distillate under 600° F. ....	35.75	86.00	78.50	90.00
Residue at 600° F. ....	64.25	14.00	21.50	10.00

The high percentage of coke in (4) was due to an insufficient heat at the end of the distillation and decreases the percentage of solids for this sample.

The operation of treatment was carried out by immersing two prismatic blocks (as described) 4 in. × 4 in. × 13½ in. in an average sample of each oil. The data involved may be condensed as follows:—

Number of sample	1.	2.	3.	4.
Colour of oil .....	Black	Green	Green	Green.
Temperature of oil	135° F.	131° F.	134° F.	145° F.
Oil absorbed per cubic foot.....	11.87 lb.	11.93 lb.	11.96 lb.	11.62 lb.

Time of absorption, minutes .....	270	50	97	126
Superfices of two blocks, sq. in. ....	192	187	485	490
Volume of two blocks, cubic in.	422.9	18.6	115.3	422.9
Specific gravity of wood .....	0.619	0.618	0.581	0.656
Colour of treated wood .....	Black	Olive green	Light brown	Light brown

After removing the samples from the bath, and wiping off the excess of oil, they were exposed to evaporation in a sheltered room, but with free access of air. The samples were suspended side by side, and the weights taken daily during the first 10 weeks, and weekly thereafter. During the first 19 days each set lost weight, in consequence of the natural volatility of the oil, but after this date losses or gains were found to occur according as the temperature and humidity of the atmosphere varied.

The weekly course of evaporation at the end of 30 weeks showing:—

Number of sample.....	1.	2.	3.	4.
Percentage of loss of the oil absorbed	15.32	32.57	30.71	43.82
Ratio of loss by weight .....	1.00	2.12	2.00	2.88
Ratio of loss per unit of surface .....	1.00	2.13	2.01	2.81

respectively. Commercially speaking, these figures are very significant. From them it is seen that in order to have 12 lb. of oil per cubic foot remaining in the timber after 30 weeks of similar exposure, the quantity of oil which must be injected will be, in the place of 12 lb., the following quantities:—

Number of oil.....	1.	2.	3.	4.
Lb. per cubic foot.....	14.17	17.80	17.32	21.35

Not an inconsiderable quantity when it is considered that the quantity of oil injected practically determines the cost of the treated timber.

The preceding determinations were supplemented by others carried out under the conditions involved in the usual creosoting process—heat, vacuum, and oil pressure.

The vacuum was carried to 27 inches of mercury and the pressure to 200 lb. per square inch or less as the oil treated with required.

The samples, as before, were obtained from several of the New York dead oil companies, and were prepared in the manner already described. The wood creosote oil was the same as that already used. The three dead oil samples, numbered here 6, 7, and 8, showed the following percentages, by weight, at 50° F. when analysed in the same manner as the preceding samples:—

Number .....	6.	7.	8.
Water.....	0.43	1.31	1.90
Indifferent oil .....	47.51	18.60	31.68
Tar acids .....	16.39	9.30	6.03
Solid bodies (naphthalene) .	32.83	69.03	58.80
Coke .....	1.16	1.57	1.44
Loss .....	1.08	3.19	0.47
	100.00	100.00	100.00

And by volume:

Distillate under 534° F. ....	68.00	85.00	39.00
Distillate under 600° F. ....	91.66	92.00	52.00
Residue at 600° F. ....	9.00	8.00	48.00

The data in this case was :

Number of sample .....	5.	6.	7.	8.
Oil injected per cubic foot .....	11'3	10'8	10'0	10'6
Superfices of each two blocks ...	496	496	496	496
Volume of each two blocks.....	432	432	432	432
Specific gravity of the wood ....	0'619	0'605	0'567	0'588

These samples were exposed to a somewhat higher (summer) temperature than the preceding, but otherwise in the same manner. After an exposure of eleven weeks the ratio of loss calculated to the unit of surface was found to be as follows :—

Number of sample .....	5.	6.	7.	8.
Ratio of loss .....	1'00	2'38	2'64	1'62

the wood creosote oil again being taken as unity on account of showing the least loss.

The relative volatility of the corresponding constituents of the wood creosote oil and dead oil was obtained by injecting samples of wood with each constituent and determining the loss in weight from week to week. The samples of wood taken were the same in size, and the exposure was simultaneous with that of the crude oils themselves.

The actual losses in ounces after 11 weeks of exposure are as follows :—

No. of Oil.	Constituent used.	Specific Gravity of Wood.	Oil Injected.	Ratio of Loss Per Unit Surface.
9.	Indifferent oil, dead oil	0'560	8'2	6'30
10.	Indifferent oil, wood oil	0'626	7'6	7'44
11.	Refined phenols.....	0'647	10'6	8'36
12.	Refined creosote .....	0'611	10'9	6'41
13.	Crude phenols .....	0'592	11'2	7'41
14.	Crude creosote .....	0'620	11'3	3'35
15.	Naphthalene.....	0'642	9'7	6'44
16.	Paraffin resin .....	0'544	11'6	1'00
17.	Heavy oil .....	0'600	9'5	1'62

Further comparison on the volatility of the crude oils and their constituents were made by exposing equal weights of each simultaneously in open vessels, the surface of exposure being the same in all cases. Such an exposure, depending as it does upon the viscosity of the oil and other considerations, does not represent the conditions at play in practice, but confirms the general results which would be indicated by the analysis of the oils and which were found to be true on exposing the treated blocks.

In comparing the crude oils the wood creosote oil is taken as unity, and for the constituents the wax or paraffin resin is similarly taken. The ratio of loss was found to be :—

No. of oil .....	5.	6.	7.	8.	9.
Ratio.....	1'00	1'84	2'01	1'09	8'80

No. of oil .....	10.	13.	14.	15.	16.	17.
Ratio.....	47'53	15'73	9'26	15'66	1'00	6'00

The absolute percentage of loss by such an exposure of 12 weeks was found to be 12'1 and 1'5 for the wood creosote oil and paraffin resin respectively.

By an examination of the daily variation in weight of the four wood samples, 1, 2, 3, and 4, treated by simple immersion, it was found that the dead oils not only showed

the losses referred to, but also were found to have sustained the greatest gains during days of great humidity. These results, found by comparing the variation for each day with the temperature and relative humidity for that day, were found to be quite uniform. This was further confirmed by exposing the four samples in the open air to the action of rain, dew, and sun-heat. This greater susceptibility to moisture, on account of evaporation, offers greater opportunities for the entrance of the germs of destruction, and thus in part destroys one of the main purposes of the creosoting process—the rendering of wood impervious to air and water. In considering the data here presented it is obviously necessary to compare the losses by evaporation in each constituent with the quantity of that constituent in the crude oil as shown by the analysis.

No absolutely uniform relationship of the evaporative tendency in the different samples could be looked for, since there are probably modifying circumstances at work in the case of the volatility of semi-solid bodies in wood which would not come into play in ordinary cases of evaporation.

In the case of the comparative solubilities of these oils, which the writer is at present investigating, these disturbing conditions again come into play and considerable light has yet to be thrown upon the subject.

Comparative tests as to the immunity of these oils and their constituents from the sea-worms are now being made by exposing the samples here described at places on the North Carolina coast, where ordinary timber is destroyed very quickly. The samples exposed were those treated by immersion (1 to 4), those treated by pressure (5 to 17), and another complete series of crude oils and constituents which have not been exposed to evaporation.

Works, in which timber treated with wood creosote oil is exposed, are to be found on the Atlantic, Gulf and Pacific coasts of the United States, and at the eastern terminus of the Panama, and of the Nicaragua canal.

The oldest authentic record of timber treated with this oil and exposed where the teredo and limoria rapidly destroy untreated timber, is six years. The writer has recently examined a locality at the mouth of the Cape Fear river, where piles treated with wood creosote oil have withstood the attacks of the worms for five years. The latter is three miles from sea, and so infested with the worm that common one-inch plank is destroyed in three months and unbarked piles in two years. It is considered here that the wharves, though not sustaining any great weight, need to have the piles removed every two years. In one case, two piles treated with wood creosote, and standing close together, after having been driven five years are still perfectly sound. The uncreosoted tide gauge nailed to the piles has long since been cut off to high-water mark.

The wharf used for the United States Custom house was built of both creosoted (about 50 in number) and uncreosoted piles. All of the former examined by the writer were sound, while the untreated piles, in every case, showed the presence of the worm.

That timber treated with the wood product has been entered by the worm is an unfortunate fact, though the writer has never found either the teredo or limoria in any of the timber he has examined. Samples sent to the laboratory and showing evidence of the worm have, as in similar cases with dead oil, been evidence of the efficacy of the oil, for in all such cases the injured wood was nearly white and showed the absence of oil, while pieces taken at the same time from adjacent piles were uninjured.

The failures of creosoted timber in America (whichever oil may have been used) is for the most part traceable to the use of heart wood or wood directly from the river.

An insufficient quantity of oil is also a great source of failure.

Time has not yet allowed of a comparison of the relative values of the two oils considered here, but from the writer's observations the advantages of each may here be condensed.

The dead oil shows a smaller percentage of water, a larger percentage of solidifiable constituents, and is handled more easily in the creosoting cylinder.

The wood creosote oil is free from ammonia (which is considered to hasten decay), is more uniform in its

constitution and less volatile and soluble when exposed to air and water.

The efficacy of the latter oil has been well established where used, but the comparative values of the two oils can be determined only by time.

#### DISCUSSION.

The CHAIRMAN said that it was always gratifying to receive communications from members not in direct and immediate contact with the home sections of the Society. It afforded an additional proof of the interest which the British Society of Chemical Industry created among technologists elsewhere, and especially across the Atlantic. A considerable proportion of the members of the Society were in America, and it was a great compliment to the Society that so enterprising a people should value the Society's Journal so highly. With regard to the communication itself, it was to be regretted that they had not before them the tables referred to. He was personally sorry for that, because he wanted to ask some questions relating to them. He assumed that the conclusion drawn by the author from his comparison of wood creosote with coal-tar creosote was in favour of the former; but whether he had substantiated that conclusion was another question. The scientific interest of the comparison was very considerable, but it had not the same practical interest in this country, because we had not here the facilities for getting the wood creosote so cheaply. In that connexion he hoped that Mr. Clark had made comparisons between the life of wood preserved by creosote and by other methods now in vogue. In a book published as long ago as 1875 by Messrs. Spon, Mr. Britton, a gentleman in the Surveyor's Department of the Metropolitan Board of Works, had attempted to cover the whole field of the preservation of timber, especially from dry rot. If his memory served him, preference was given to certain metallic salts, and chiefly to perchloride of mercury. A process for such treatment of timber, patented by Kyan, was at one time very successful, but was ultimately dropped on account of expense. But it was remarkable that in connexion with the very purpose referred to by the author of the communication, namely, the preservation of timber exposed to the action of water, there had been a very noticeable revival of the employment of metallic salts of various kinds. The subject was therefore again occupying the attention of constructive engineers; and if Mr. Clark's comparisons included not only wood creosote and coal-tar creosote but metallic salts also, they would be especially interesting and valuable, if only by reason of their being brought down to a much more recent date than any hitherto existing.

Mr. A. H. ALLEN said that an exceedingly able—indeed classical—paper on the subject of creosoting timber had been read before the Institute of Civil Engineers a few years ago by Mr. S. B. Boulton, and that paper exhausted the subject up to its date. He agreed with Mr. Boulton that the use of phenoloid bodies, such as existed in wood-tar or creosote from other sources, was not all that was required, because they were not insoluble, and were, therefore, apt to be washed out in the course of time. He thought that much better results were to be obtained by absolutely filling the pores of timber with insoluble substances. That was the reason for using the thick coal-tar oils rich in naphthalene which were so extensively employed at present. He himself was the co-inventor of a process for creosoting timber, which never came to maturity, because on inquiry he found that there was no real demand for such processes. Engineers were quite willing to use the process, even on a large scale, but only at the inventor's expense; and they required from 7 to 10 years to form an opinion of its merits. Timber exposed between wind and water deteriorated very rapidly, and in that case they had to deal with worms, not dry rot. The *Teredo navalis* was a worm with a saw-like arrangement at one end, by means of which he tore the timber into sawdust and passed it through his body. No doubt he possessed digestive organs of some sort, but he (Mr. Allen) was informed on high authority that the main cavity in the *Teredo* was not a digestive canal of the ordinary kind, being apparently used chiefly as a convenient means of passing the sawdust out at the other end. They were thus dealing with conditions very different from those which

ordinarily existed. If one could find a substance which would give the *Teredo* chronic indigestion, that would be the most valuable agent to employ. If the agent used were soluble, it was washed out by the water; if completely insoluble, it had no effect on the *Teredo*. So at present they were on the horns of a dilemma. It was very difficult to improve on the processes at present in use, because engineers were unwilling to go to any expense in testing new methods. In fact, they would very much rather replace timber as occasion required than treat it by any process which had to be paid for.

Dr. C. R. ALDER WRIGHT had begun to hope, from some remarks made by the editor in reading the communication that the products of the distillation of the *Pinus sylvestris* were going to be instrumental in abolishing some of the evils that arose from the consumption of alcohol. They were told by Dr. Ward Richardson that methylic alcohol might be taken with impunity as compared with the ethylic fluid; and from the glowing description of the wood alcohol on the table he was in hopes that if it were obtainable in sufficient quantity and of uniformly good quality, it might become a most important social agent. But a taste of the sample had dissipated the anticipations he had formed. It had a most diabolical flavour, and he did not envy the man who should acquire a taste for it. With regard to the variety of products obtainable from the *Pinus sylvestris*, he thought that they merited very considerable attention from British wood distillers, as showing them that woods other than those they usually dealt with yielded products of very great commercial importance. From that point of view, if from no other, the paper would be very valuable to the Society.

Mr. WATSON SMITH said, with regard to the evaporating powers of dead oil and wood creosote respectively, Mr. Clark had given some data which showed that the former evaporated more per unit of surface than did the latter. That was quite natural, and was due to the fact that naphthalene, which was largely contained in coal-tar dead oil, was a body which, though possessing a high boiling point, evaporated or volatilised at very low temperatures. On the other hand, wood creosote would contain such bodies as guaiacol and creosol, and those bodies, while having high boiling points, were not so peculiarly volatile at comparatively low temperatures. On the other hand, naphthalene was thus volatile. To enforce the argument as to volatility, he had only to remind them that naphthalene had been used to adulterate camphor, a substance of eminent volatility. Then again, the guaiacol and creosol in wood creosote were associated with paraffin, a substance which had a still higher boiling point than naphthalene, but which was practically non-volatile at ordinary temperatures. All these circumstances would tend to account for the superior action of wood creosote as regarded evaporation. The author appeared to have tried many experiments with antiseptic salts, but found that they did not answer, as they were too easily washed out of the wood. Dr. C. R. Alder Wright had referred to the unpalatable flavour of the wood naphtha; that might be due to a small quantity of terpenes, which whilst efficiently denaturing the alcohol, could not affect it injuriously for the varnish-maker, to refer to one industry only.

Dr. FRANKLIN S. CLARK sent the following reply:—

The views expressed by the Chairman, Mr. Thomas Tyrer, in reference to the metallic salts, so far as their antiseptic properties are concerned, agree, I believe, with the experience of preserving wood not exposed to water. The trial of zinc chloride for preserving railroad ties on the German railroads is favourably reported upon, and may be cited as an instance corroborating the above-mentioned views. Where wood is much exposed to the solvent action of water, as in the case of marine works, the salts are quickly washed out and their antiseptic power has but a short time to exert itself. No instance has come under my notice where these salts have preserved wood against the sea-worms in American waters.

The views presented by Mr. Allen bring up the question of the value of the antiseptic action of different agents compared to their mechanical effect. This is a very important phase of the subject, but was not taken up in the paper, the latter aiming to present the mechanical action of the two

oils when injected into wood. The antiseptic action of the constituents of these oils is certainly an important consideration in creosoting, but it is still an open question among the coal tar authorities how much the preservation of wood is due to the germicidal and how much to the physical action of the agents used. The comparative values of the two oils can only be determined by actual trial under similar conditions.

The high boiling point of naphthalene does not indicate its permanency under atmospheric temperatures, as will be shown by the comparative determinations of the paper. The relative degrees of evaporation of water and oil of turpentine at ordinary temperatures shows that the boiling point alone is not a criterion of permanency.

As to the solubility of the comparative constituents of the two oils, it is found that the heavy oil and paraffin resin, the constituents of the wood oil corresponding to the naphthalene of dead oil, are, like naphthalene, practically insoluble in water.

The comparative solubility of the phenoloid constituents of each is somewhat indicated by examining the solubilities of carbolic acid, cresylic acid, &c., compared to guaiacol, cresol, &c., the constituents of wood creosote. This comparison would lead to the belief that the latter were less liable to wash out from treated wood.

The germicidal properties of these several constituents would throw much light upon their values for preserving wood, but these investigations have never yet been made.

The caustic taste of the wood alcohol, referred to by Dr. Alder Wright, is traced to the crude wood acid which forms the basis of the manufacture of wood alcohol.

In the distillation of hard wood, the oily products are very viscous and heavy, which fact explains the ready separation of acid and tar and the slight tendency of the acid to take the oily bodies in solution. In the case of the distillation of pine wood, however, the presence of turpentine-like bodies causes the specific gravity of the acid and oil to nearly approach each other, causing thereby, to a greater or less extent, a solution of some of the oily components of the tar. These constituents are difficult to remove from the acid by any commercial treatment, and give a biting taste to the resulting methyl alcohol.

MR. A. NORMAN TATE IN THE CHAIR.

OPENING ADDRESS BY THE CHAIRMAN, MR. A. NORMAN TATE, ON SOME AIDS TO THE FURTHER DEVELOPMENT OF CHEMICAL INDUSTRY.

(ABSTRACT.)

AMONGST other aids to which we may now look to assist in the development of chemical industry are those that may be termed educational, and the present movement towards technical education, which has been largely promoted by the passing of the Technical Instruction Act, ushers in a new

era of national educational effort that must greatly aid all our industries. Whether the Society as a society should take any definite action in this matter is a subject for consideration, but there are many ways in which individual members can assist.

There are two modes of teaching in connexion with technical instruction, viz., hand work (of course including all such manipulations as chemical laboratory work), and oral teaching, and we have to be careful that there shall not be an excess of oral teaching, lest we perpetuate under the name of technical education some of the worst evils of ordinary instruction as now too often given.

We must once for all clearly understand that there is no possibility of teaching trades or manufactures except in the actual workshop or manufactory, and that any attempt to teach them in schools, colleges, or other teaching institutions must end in failure. And I would go further to say that no profession can be thoroughly well learnt without training amongst those who practice it.

It has often been said lately that what is really wanted is that all-round training of eye, hand, and general faculties that shall give facility in observation and manipulation in various directions, and the introduction of manual work into our board and other elementary schools must help greatly in this direction. And the introduction into such schools of the teaching of the elements of science should give that knowledge of general facts that underlies all industrial occupations, provided that it does not run in the direction of much of our present school teaching—mere statements of scientific facts, without ample accompaniment of practical illustration of their applications. It is desirable that similar teaching should be given in what are considered our higher class elementary schools, many of which are woefully deficient in scientific and practical training.

But, of course, all this early training is of a general character, affecting all occupations alike. It is when the pupil leaves ordinary school studies that more specific instruction should commence. Any instruction of this kind must be given to our working classes either when continuing partly at school or in evening classes. Now we have a large number of science and art schools and classes, and in many places good classes under the City and Guilds of London Institution, and these have already done immense service, but there is required more definite organisation—something on the lines of "organised science schools" mentioned in the Science and Art Directory for this year, at page 34, but with that curriculum modified to suit special places and circumstances.

There must follow a distinct advantage in working such schools somewhat on the lines of the Science and Art Department, inasmuch as it has shown itself so thoroughly in earnest in insisting upon practical teaching as against "cramming," and although it has had largely to rely upon written answers to questions to assess results, yet its system of examination has gradually become a really good test of sound practical teaching, and in many subjects its questions are models of searching investigation into the *practical* knowledge of the pupil as against ordinary examination "cram." And in organising modes of instruction it has insisted upon really efficient laboratory instruction, not only in chemistry but in physics, biology, and other branches of science, and has, by its careful inspections, largely prevented "slipshod" work.

It is desirable that the attention of workpeople should be more directed to such schools. The majority of students now enter them with the object of gaining some intellectual, pleasant occupation for their leisure time, and not because they think they will gain knowledge that will assist them in their ordinary avocations; and we may all do more than we are doing in calling attention to these schools and helping them by all means in our power.

In these evening schools the ordinary school course must be followed up by more advanced teaching, which, as regards chemical industries, does not mean teaching in chemistry and physics only, with sufficient mathematics to work out problems set by an examiner. The lecture courses must be supplemented by laboratory work, or I believe it would be far better if these ran concurrently, for in evening classes there is not too much time to spare, and thoroughly

good practical experiments with the theory of their action explained at the time would be of far more value than many of the separate lecture and practical courses now in vogue.

An enlargement of such a course as the alternative elementary chemistry course of the Science and Art Department is in the direction I mean, for this is infinitely superior in imparting sound chemical instruction to the usual lecture courses. Then other subjects should be taken, such as will give some good knowledge of the nature of materials used in the construction of buildings and plant, and there should be instruction in the elements of mechanics, in building construction, machine construction, and drawing; all these, however, dependent upon the special occupation of the student and the time at his disposal. A study of these extra subjects is, I consider, most essential, especially for those who have any responsible charge in connexion with our chemical industries, for it has been far too frequently shown that a chemist who is a chemist only, however thorough his chemistry, is not the proper person to conduct chemical manufacturing work, for numerous are the chemical processes that have failed, although sound as regards their chemistry, because attempts have been made to work them with totally unsuitable plant, and with ignorance or disregard of circumstances that could not fail to materially modify the chemical reactions and prevent success.

This is why I recommend attention to the organising of subjects in science schools, so that the proper subsidiary subjects may be taken in connexion with the main subject. The City and Guilds of London Institute has done something in this direction.

Progressing from that teaching which forms the scientific groundwork, and coming to the more purely technological instruction, what is the training that can be given? Each locality of chemical industry should organise special courses bearing upon its own special industries, but such courses should not be mere lecture courses simply described by the aid of a few diagrams, models, or specimens. The processes described must be, as it were, turned inside out, and every possible detail that affects success or failure carefully explained.

But the sort of courses that I think would be of most service would be good practical expositions of general operations, such as would deal with the operations of fuel-burning, ebullition and evaporation, solution, crystallisation, fusion, &c. These could be made useful in connexion with the work of almost any manufactory, and would be very serviceable to those who cannot give time to follow out special courses, or who are not engaged in any special work.

Having organised such instruction for our workpeople, we may next endeavour to stimulate them to study by giving preference in their employment to those who show themselves specially apt, and by offering scholarships and such like rewards for those really hard working intelligent students who wish to go further in their studies in higher schools or colleges, and thus help them forward in the world. I think the Society of Chemical Industry might well consider present and new methods of instruction in chemical technology, and help good work by offering scholarships and by other practical aid and suggestions.

But now, leaving the consideration of the education of our workpeople, and coming to the education of those who are to take higher grades in our chemical industries. First of all, it is necessary to give attention to our ordinary middle-class schools, which frequently are very deficient in scientific and practical training, and then we have to consider how far we can organise schools for some such scientific and preliminary technological teaching as I suggest we should provide for our workpeople. And next we have to look to our higher colleges and universities, which should give the highest training possible, and more especially confine themselves to such work instead of overlapping the work of more elementary schools. That the more elementary teaching should be given in these higher colleges is probably now necessary, because where many of them exist, being of late establishment, the ground has not been well prepared for them, and students do not enter them sufficiently advanced for the higher branches of study.

For the more technological work something in every way more complete is necessary than what I have described. In

workmen's evening schools and others giving similar instruction, again there should not be too much of the lecture course without ample opportunity for full demonstration of all the principles involved in the processes; and I cannot help but think that even in these higher schools and colleges, instead of some of the courses on special processes, courses on general operations would often prove more useful.

But who is to give this advanced technological instruction? Unfortunately, teaching of technology is not usually considered advanced, as it is usually put down for study under quite subsidiary circumstances, although I consider it should be just the reverse. Mr. Levenstein, in a late address at the Technical School, Manchester, stated that we were short of teachers, and I quite agree with him. One of the greatest difficulties in teaching technology in this country is to get suitable teachers. There has been hitherto no inducement to really capable men to teach. The merest pittance has been awarded for such teaching, and in one or two of our largest colleges it is a scandal that the teaching which bears most upon useful practical work in connexion with our industries should be so poorly paid as compared with that of the men who do the more elementary work. Consequently, men capable of teaching, but with a bent for technology, have occupied themselves in the more practical manufacturing pursuits, in which remuneration has been more in proportion to their labours, and technological teaching has been left more especially to those whose training has been chiefly that of the school or college, with a smattering gained by an occasional walk through a manufactory or a more or less diligent study of technological works. If we are to alter this and get good men to teach we must see that such teaching is given a more honourable position than it has hitherto held, and one which its importance deserves. If we follow upon some such lines as those I have endeavoured to mark out, I cannot but think that this new era in technical instruction will prove of the greatest advantage to our industries.

#### INDUSTRIAL MUSEUMS.

But now I wish to speak of technical, trade, and commercial museums as aids to industries. Our ordinary museums are, I fear, too much neglected to be of much educational aid, and we are miserably deficient in industrial museums. Yet a well-arranged series of raw products, descriptions of their characters and of the processes by which they are converted into new materials, with specimens of these new materials, can prove of great help in the study of an industry, and an incitement to further work in designing new processes, looking for new material and making serviceable that which has hitherto lain idle. Such collections should be supplemented by carefully prepared descriptive handbooks and by frequent lectures illustrative of the nature and uses of the several specimens. There are numerous such museums on the Continent and in America. I have seen lately the Commercial Museum of Brussels and one in the neighbouring city of Antwerp, which latter is an outcome of the Antwerp Exhibition of 1885, and to this annual subsidies have been voted both by the municipal and provincial authorities; but one of the most interesting and instructive that I have seen, and one that may well be taken as a model, although of comparatively small size, is at Haarlem in Holland, and in this is an excellent exhibition of the products of the Dutch colonies, with illustrations of the mode of their collection or production, and the uses to which they are applied. A collection of similar character should exist in this city of Liverpool, the largest port in the world. It would materially help on commerce and industries, and should contain raw and manufactured products imported and exported, with their technical histories and illustrations of the uses to which they are applied, and new materials with suggestions as to their possible uses. A large number of substances come to Liverpool year after year that are never made use of because they are never heard of beyond one or two brokers or merchants, who, not being able to examine properly into their characters and capabilities, relegate them to the category of useless articles, for, owing to want of training in scientific and technical knowledge that would be of service to them in their everyday business

many of our merchants and brokers are unable to deal, even in an elementary way, with substances a little different to those they are accustomed to.

And a museum that would be serviceable in a port like Liverpool would be, I believe, of even more value in centres of industrial activity.

Such museums would be fitting adjuncts to technical schools; and following on these there should be—

#### LABORATORIES OF RESEARCH

Specially arranged for the examination of raw products and manufacturing substances. In these new imports or native products might be subjected to tests to ascertain the purposes for which they are suited; and substances already known, but not in use, might be systematically examined to endeavour to find uses for them. A large number of new substances are brought into the different ports of this and other countries every year, that, properly used, could be made of commercial value, but now, for want of careful examination, remain noticed only for a short time as curiosities, and are then forgotten. Laboratories of research could also be made available for finding new uses for substances already employed, and probably frequently outlets would be found for commodities with which the market is overstocked. Supplementary to such institutions should come—

#### TECHNOLOGICAL LIBRARIES.

With ample supply of scientific and technological literature, although to give them a completeness much improvement is desirable in our technological literature, for many of our technological handbooks are but "hashes" of a few larger works, and these are often but of indifferent character. Probably the best example of technological literature that has been produced is our own Journal.

#### INVESTIGATION OF ANALYTICAL PROCESSES.

All the topics I have yet dealt with are more especially educational, but now I turn to something different to point out how greatly chemical industrial, and commercial transactions would be benefited by a thorough investigation of processes employed in the examination of raw and manufactured substances and material in process of conversion. Many processes, excellent in themselves, give, in the hands of different operators, results so far different as to lead to annoyance and inconvenience, and this frequently arises from some very slight difference in details of manipulation.

Other processes again vary in results according to variations in the substances examined, such as where the determination of the main constituent is modified by presence of impurities or small quantities of other substances, the action of these extraneous matters being often overlooked.

It would, I think, be very useful to bring before this Society papers comparing results on the examination of certain products and determination of certain constituents when treated by different analytical processes or by essentially the same process under somewhat different conditions.

It is most important for chemical transactions that differences in commercial analyses should not occur, as oftentimes they mean not only delay in settling transactions but considerable difference in money values, &c.

But whilst speaking of differences in analyses I cannot help referring to sampling operations, which are a more fruitful source of discrepancies and require most careful attention; indeed, to ensure accuracy in assessing the true value of a commercial article sold on test, the sampling operation is almost, if not quite, as important as the analytical.

I wished to have alluded to the use of the microscope in chemistry, as its employment is every day becoming more important, but must now close, and trust I may have an opportunity of dealing with that subject and other aids to chemical industries on a future occasion.

Dr. HURTER proposed and Mr. E. K. Muspratt seconded a vote of thanks to Mr. Norman Tate for his address, which was supported by Dr. Campbell Brown, and to which Mr. Tate replied.

## Newcastle Section.

Hon. Local Secretary and Treasurer:

Dr. J. T. Dunn, The School, Gateshead.

Notices of Papers and Communications for the Meetings to be sent to the Local Secretary.

Meeting held in the College of Science, Thursday,  
November 6th, 1890.

MR. JOHN PATTINSON IN THE CHAIR.

#### CHAIRMAN'S OPENING REMARKS.

ALLOW me to thank you for the honour you have conferred upon me in electing me Chairman of the Newcastle Section of the Society of Chemical Industry. Fifteen years ago I occupied a similar office in the Newcastle Chemical Society, which became amalgamated, very wisely, as I think, with this Society in 1882, and although you have on more than one occasion since then asked me to become your Chairman, I have always felt it my duty to endeavour instead to induce others closely identified with the chemical industries of the district to occupy this post, and thus to interest themselves in the welfare of the Society. The time has now arrived, however, when you again wish me to take this office, and you have done me the honour of electing me. I shall try to fulfil its duties to the best of my ability.

I do not intend troubling you with a formal inaugural address, but rather to imitate the example of the London Section and that of some other Sections in this respect. They have no inaugural addresses. I believe that it is desirable to get rid of the notion that Chairmen of Sections are expected to prepare an elaborate inaugural address. Such a notion is calculated, I think, to deter many gentlemen from accepting office who are in every way well fitted to act as Chairmen, but who may not have the time to prepare, or who think they have not matter of sufficient interest for, an elaborate address on chemical subjects.

There are, however, one or two subjects of special interest to most of our members of which I think mention should be made on this occasion. The first is the much-talked-of union of Leblanc soda manufacturers. The prospectus of a company to be called "The United Alkali Company, Limited," is just now being issued. Should this company be floated, nearly the whole of the Leblanc soda works in the United Kingdom, numbering about 50, will become the property of one large concern, and be managed by one and the same board of directors. Much has been written in the newspapers in condemnation of this project by some of the consumers of the produce of these chemical works and by other interested persons. There is, however, much that is exceptional and peculiar in the present position of the Leblanc soda makers which leads to the conclusion that, from their point of view at any rate, this union is a very wise and prudent step. We all know the circumstances. Carbonate of soda can be much more cheaply made by the ammonia-soda process than by the Leblanc process, and the ammonia-soda makers consequently command the market for this article. The price of alkali has thus been brought down so low that its manufacture by the Leblanc process has, to say the least, ceased to be remunerative, and the costly plant used in the Leblanc works would probably ere

now have been entirely disused were it not that the hydrochloric acid resulting from the Leblanc process (which acid at one time was regarded as a waste by-product) has always been and still is the cheapest source of chlorine for the making of bleaching powder and chlorate of potash. The by-product has thus become the chief manufacture and source of profit of the Leblanc soda makers, and the soda may now be considered the by-product. There have been during the past six or eight years various announcements that new and cheaper sources of chlorine had been discovered which would supersede the hydrochloric acid of the Leblanc process, and thus give the deathblow to the Leblanc soda makers, but in spite of all these prognostications, as a matter of fact the whole of the 150,000 tons per annum of bleaching powder made at the present day is made from the hydrochloric acid of the Leblanc process. Electrolytic bleaching in paper works, too, has not yet proved the success that it promised to be, so that the demand for bleaching powder is still undiminished. Unfortunately for the Leblanc manufacturers the Leblanc works in existence could make more bleaching powder than there was a demand for, and hence we have had the makers competing with each other until bleaching powder as well as soda was sold at an unremunerative price. Under these circumstances, towards the end of 1883 the bleaching powder makers formed a combination to restrict the make, and thus to secure a price which would enable them to carry on their works. This combination was for some time successful in its object, and it lasted until the end of 1889, when, owing to some of the makers proving disloyal to the arrangement, it ceased to exist. Should the proposed union be carried out, the United Alkali Company will then have complete control over the quantity produced and the prices at which sales are effected. In this respect the proposed united company will have an advantage over the recent bleaching powder combination. In other respects I do not see that the effect upon the trade of the country and upon the users of bleaching powder is likely to be very different from the effect of the bleaching powder combination existing from 1884 to 1889. Practically the present union of Leblanc soda makers is a bleaching powder combination without the possibility of disloyalty. We did not find then that the price of bleaching powder was raised to a price which seriously affected the paper makers and others, nor need we fear that the prices will now be raised exorbitantly high. The directors of the united company know as well as any other business men that very high prices can only result in bringing a host of competitors into the field, and the consumers of caustic soda and bleaching powder are thus safeguarded against any serious rise in prices over and above those necessary to carry on the manufacture so as to yield a reasonable amount of profit.

How will the proposed union affect the Society of Chemical Industry? Will it reduce the number of its members, or lessen the number of papers contributed to its meetings? I am inclined to think that it will not seriously affect us. Managers and chemists will still be wanted in each of the works, and there will still be the same opportunities as at present of their suggesting improvements in processes in the works and in the laboratories.

The other subject to which I wish to call your attention this evening is the question of black coal smoke. In spite of all the numerous contrivances for the prevention of smoke there is no doubt I think that on the banks of the Tyne the nuisance from black smoke has considerably increased in recent years. In most cases the stoking of furnaces, used only for the raising of steam, seems to be carried on utterly regardless of the quantity of smoke emitted or of the dirt and discomfort caused to those who have to live in the smoke-polluted neighbourhood. We sometimes pride ourselves upon the striking architectural and natural features of our city as seen in approaching it from the south, but in my intercourse with travellers through Newcastle-on-Tyne, I have found that the only feature noticed in most cases is the extreme smokiness of the place. This state of things should not exist. It is quite time that the attention of manufacturers and the general public should be called to the matter, and that an attempt should be made to lessen the evil. I am not one of those who think that, under all circumstances, it is an easy thing to entirely

prevent even the occasional formation of some smoke when burning Newcastle coal; but I am quite sure that with suitable appliances and with a little care very much of the black smoke now sent out from boiler fires can be prevented. I am glad to be able to announce that this question of smoke prevention has just recently been taken up by a number of gentlemen in various parts of the country who have formed themselves into a "Committee for Testing Smoke Preventing Appliances." Mr. A. E. Fletcher, the respected Chief Inspector of Alkali Works has taken great interest in the formation of this association, and he is the chairman of the executive committee. It is not the intention of the association to harass the manufacturer by legal proceedings. On the contrary the aim is to aid manufacturers by collecting information respecting the efficiency and general value to the coal consumer of smoke-preventing appliances and methods, and to employ disinterested experts to thoroughly test these appliances and methods when using various qualities of coal. The manufacturer will thus learn, on trustworthy authority, what smoke-preventing appliances suitable for his purposes exist, and he will be saved from the fate of many manufacturers who, on the representations of the inventors, have fitted up costly forms of apparatus which on trial have proved to be neither economical or efficacious. I have no doubt that the labours of the committee will assist very materially in obtaining an abatement of the smoke nuisance. The work they are undertaking will however take some time to complete, and much expense will necessarily be incurred. I trust the members of this Section and all manufacturers in this district will as far as possible give this project their sympathy and support.

We look to the members of this Section to interest themselves in providing papers and notes for our monthly meetings during the present session and thus to add to the progress and success of our Section of the Society.

## SOME NEW AND IMPROVED ANALYTICAL METHODS FOR ALKALI WORKS.

BY PROFESSOR G. LUNGE.

THE first edition of the "Alkali Makers' Pocket Book," edited by Dr. Hurter and the writer, has found so much favour with the chemical public that a second edition has been called for, which will be issued shortly. Although the great majority of the analytical methods prescribed in the first edition of our book have stood the test of five or six years' practical application in a large number of laboratories, it stands to reason that this space of time has not passed by without bringing under our notice the desirability of improving some of the methods and tables then given, and adding new ones for wants which have made themselves felt in the meantime. Since, according to the plan of the "Pocket Book," we can give there merely the practical prescriptions for carrying out the tests, and these in the fewest possible words, it seems appropriate to choose another channel for laying before our fellow workers the reasons why we have made a number of alterations and additions to the "Pocket Book," and giving sufficient details for proving the accuracy of the new methods proposed; and these notes will, I hope, possess some interest also for those chemists who do not consult the "Pocket Book."

The bulk of the work to be described has been done by myself, with the help of some of my assistants; where suggestions have come to me from outsiders I shall duly mention them.

### 1.—ESTIMATION OF SULPHUR IN PYRITES.

This is merely mentioned to state the fact that the method described by me previously, and adopted in the "Pocket Book," has been over and over again proved to be equal in accuracy to the best otherwise known, and far superior to them in point of convenience, speed, and facility of execution. A somewhat serious attack was made upon it by Jannasch and Richards, but Professor Jannasch has

himself acknowledged (J. prakt. Chem. 40, 236) that their criticism was caused by a confusion of my older with my more recent method, which they had entirely overlooked, and that my new method gave, in his hands as well as in my own, the most accurate results. This has been conclusively proved by the comparison of methods made by two of my students, Messrs. Barbezat and Obregia (Zeits. f. angew. Chem. 1889, 473), and this matter may now be considered as settled.

For the testing of *burnt ore* (pyrites cinders) we now prefer the method of Watson (this Journal, 1888, 305) which was found to be preferable to all others tried in my laboratory.

## 2.—TESTING THE PYRITES BURNER GASES.

Wherever the burner gases are tested, it is probably always done by Reich's method, as described in the "Pocket Book," that is, aspirating the gas through a measured quantity of iodine solution, and ascertaining the volume of gas required for decolorising the iodine. This shows the quantity of sulphur dioxide present. Since, however, it has been proved by many observers that the gases contain sulphur trioxide, sometimes up to one-tenth of the total sulphur present, the above-described test must be declared inaccurate, and I propose, instead, estimating the *total acids* by passing the gases through a *caustic soda solution*. Very much depends in this case upon the indicator to be chosen.

The indicator must be affected exactly alike by  $\text{SO}_2$  and  $\text{SO}_3$ , otherwise the results will not give any useful clue to the working of the process.

Former investigators (especially R. J. Thomson, myself, and, much later, Blarez) have proved that litmus and most other ordinary indicators give indistinct results; methyl-orange shows the point of saturation for  $\text{SO}_2$  at the point when  $\text{NaHSO}_3$  is formed; only phenolphthalein sharply indicates the point when  $\text{Na}_2\text{SO}_3$  is formed, so that only this indicator can be used in the present case, since it is indispensable that the point of saturation be the same at whatever degree of oxidation the sulphur be present in the gases.

The next question was this: Whether the absorption of the sulphur acids by very dilute caustic soda solution is as easy as that of  $\text{SO}_2$  by iodine, and whether Reich's apparatus would have to be modified for this purpose. To decide this, in the first instance a number of laboratory experiments were made under my direction by Mr. Marchlewski, with mixtures of  $\text{SO}_2$  and air in varying proportions, by means of a specially constructed gas holder in which a fairly constant proportion of gases could be kept for some time. It was soon found that it would be desirable to modify the absorbing bottle so as to become more efficient, and this has been done by adopting the form shown in Fig. 1. The inlet tube for the gas is sealed at the bottom, and is perforated below the level of the liquid with many pin-holes, through which the gases issue in many minute bubbles, instead of one large bubble. Our bottle held 410 cc. and was charged with 230 cc. of water, 10 cc. of decinormal soda solution, and three drops of an alcoholic solution of phenolphthalein. Each time after opening the aspirator tap for a moment and passing a few cc. of gas through, the bottle was shaken up for half a minute. Especially towards the end this must not be neglected, and it must be carefully observed on a white background whether the last pink tint has vanished or not. Special tests were made in the twilight and with artificial light to approach the conditions of working in factories. In every case at the end of the operation a single drop of decinormal soda solution was added in order to try whether there was not an excess of  $\text{SO}_2$  present, which would prevent the liquid from turning pink again, but this never took place. A fresh experiment can be made at once in the same bottle by simply adding another 10 cc. of soda solution, and this can be repeated several times in succession.

In the following experiments the percentage of  $\text{SO}_2$  was calculated by the formula  $\frac{100 \times 11.14}{11.14 + n}$ , in which 11.14 represents the volume of  $\text{SO}_2$  retained by the 10 cc. of decinormal soda solution, and  $n$  the volume of the water run out of the aspirator, reduced to 0° and 760 mm. With

five different mixtures of gas (A—E) the following results were obtained:—

A.				
n.	1.	2.	3.	4.
271	corresponding to 3.90 per cent. $\text{SO}_2$ by volume.	271	3.94	" "

B.				
n.	1.	2.	3.	4.
262	corresponding to 4.07 per cent. $\text{SO}_2$ by volume.	263	4.06	" "

C.				
n.	1.	2.	3.	4.
236.5	corresponding to 4.49 per cent. $\text{SO}_2$ by volume.	238	4.47	" "
		237.5	4.49	" "

D.				
n.	1.	2.	3.	4.
131	corresponding to 7.83 per cent. $\text{SO}_2$ by volume.	133	7.73	" "
		130	7.81	" "

E.				
n.	1.	2.	3.	4.
122	corresponding to 8.44 per cent. $\text{SO}_2$ by volume.	124	8.24	" "

These experiments prove that the described method yields concordant and evidently acceptable results. It was, however, a further question whether this would be also confirmed by actual factory testings, or whether in these there would be an essential and permanent difference between the soda and the iodine method. Experiments in this direction have been made by Dr. Notzli at the Aussig Chemical Works, by aspirating burner gases by means of a T-tube at the same time through decinormal soda solution and decinormal iodine solution. In these first experiments no reading of the thermometer and barometer was taken for correcting the volume of gas aspirated, hence the percentages calculated are not exact, but the results are all the same comparable with one another.

The following observations were made with successive samples, of necessarily varying percentages, but those given on the same line (for soda and iodine respectively) were always taken by aspirating at the same moment.

### SERIES A.

	10 cc. Soda Solution.	10 cc. I Solution.
Water run out ....	cc. 134	cc. 154
" ....	136	148
" ....	146	160
" ....	158	170
" ....	169	183
Average .....	149	163
Corresponding to..	7.0	6.4 per cent. $\text{SO}_2$ by volume.

### SERIES B.

	10 cc. Soda Solution.	10 cc. I Solution.
Water run out ....	cc. 164	cc. 175
" ....	136	148
" ....	122	130
" ....	101	112
" ....	98	105
" ....	95	103
Average .....	119	128
Corresponding to..	8.6	8.0 per cent. $\text{SO}_2$ by volume.

## SERIES C.

	50 cc. Soda.	50 cc. I.
Water run out ....	cc. 614	cc. 684
Corresponding to..	8.0	7.5 per cent. SO <sub>2</sub>

It is perfectly clear that in every single case the total acidity, calculated as SO<sub>2</sub>, is superior to the quantity of real SO<sub>2</sub> as indicated by the iodine. But in order to obtain a sure quantitative foundation I caused Dr. Nötzli to make a special experiment in which the thermometer and barometer were observed, and in which the acids were all oxidised by means of iodine, and the total sulphuric acid gravimetrically estimated, so that we now possess all the elements of calculation. Burner gases were aspirated at the same time though 50 cc. decinormal NaOH and 50 cc. one-tenth normal I. The temperature in the aspirating bottle (which was placed close to a large gas-pipe) was 34° C., the barometer stood at 740 mm. In order to discharge the colour of phenolphthaleïn, 650 cc. water had to be run out; the absorbing liquid, after oxidation by I, yielded gravimetrically 0.1963 grm. SO<sub>3</sub>. In order to discharge the colour of the iodine 684 cc. of water was used; gravimetric analyses showed 0.2047 grm. SO<sub>3</sub>. Now we find:—

## A.

650 cc. of 34° and 740 mm. ....	= 532 cc. of 6° and 760 mm.
To this must be added the SO <sub>2</sub> absorbed, = 50	" "
Total original gas.....	588 " "
or $\frac{55.7}{588} = 9.47$ per cent. by volume of total acids calculated as SO <sub>2</sub>	

## B.

684 cc. of 34° and 740 mm. ....	= 560 cc. of 6° and 760 mm.
Add for SO <sub>2</sub> .....	56 " "
Total original gas.....	616 " "
or $\frac{55.7}{616} = 9.04$ per cent. of SO <sub>2</sub> really present.	
leaving	0.43 per cent. of SO <sub>2</sub> present as SO <sub>3</sub>
<u>9.47</u>	

If 588 cc. of original gas, after oxidising all SO<sub>2</sub>, yielded altogether 0.1963 SO<sub>3</sub>, 616 cc. of gas must yield  $\frac{616 \times 0.1963}{588} = 0.2056$ . We really found in the iodine solution 0.2047, which is a very satisfactory confirmation.

This calculation at the same time shows what great errors are often made in factories by neglecting the temperature and barometrical pressure. Even in the above estimations there is still a slight error, since the column of water in the aspirator (whose height I do not know) ought to be deducted from the barometrical pressure; but this error, which would appear to make the percentages slightly lower than they actually were, cannot have affected the total results to a sensible degree.

I may be allowed in this place to mention a plan for testing burner gases which has been in my mind for several years past, but for which I have not yet found the means of carrying out in practice. This is—*estimating the percentage of sulphur acids in burner gases by their specific gravity*. The gaseous mixture in question contains an almost constant proportion of nitrogen, a quantity of oxygen varying between narrow limits, and a certain quantity of the acids of sulphur, together with those of nitrogen which may (and indeed must) be neglected in this as well as in the preceding method of testing. Nor is it necessary to take notice of the difference in specific gravity between the vapours of SO<sub>2</sub> and SO<sub>3</sub>, for the method in question cannot replace an exact analytical estimation, and is only intended to facilitate the control of the vitriol-making process by the ease and speed of the observation, and by the possibility of arranging a *continuous graphical check of the pyrites-burning process*.

If we put atmospheric air = 1, the specific gravity of nitrogen is = 0.9714, that of oxygen, = 1.1056. Suppose we replace part of the oxygen by sulphur dioxide, whose specific gravity is = 2.247, the specific gravity of the mixture will be raised; for instance, with 8 per cent. gas:—

$$\begin{array}{rclcl} 79 \text{ N} & = & \frac{79}{100} \times & 0.9714 & = & 0.7675 \\ 13 \text{ O} & = & \frac{13}{100} \times & 1.1056 & = & 0.1437 \\ 8 \text{ SO}_2 & = & \frac{8}{100} \times & 2.247 & = & 0.1798 \\ & & & & & \hline & & & & & 1.0910 \end{array}$$

or with 6 per cent. gas:—

$$\begin{array}{rclcl} 79 \text{ N} & = & \frac{79}{100} \times & 0.9714 & = & 0.7675 \\ 15 \text{ O} & = & \frac{15}{100} \times & 1.1056 & = & 0.1658 \\ 6 \text{ SO}_2 & = & \frac{6}{100} \times & 2.247 & = & 0.1348 \\ & & & & & \hline & & & & & 1.0681 \end{array}$$

A difference of 2 per cent. volume of SO<sub>2</sub> is represented by a difference of 0.023 in specific gravity. That is, differences of 1 per cent. SO<sub>2</sub> will be indicated by the second, and such of 0.1 per cent. SO<sub>2</sub> by the third decimal place of the specific gravity.

It is some time since Mr. Friedrich Lux, of Ludwigshafen, constructed his gas-balance, which is now generally employed for instantly or continuously testing the specific gravity of ordinary illuminating gas; and it has also been employed with some like success in the analysis of that gas. For two years past I have tried to induce Mr. Lux so to modify his gas-balance that it could be used for acid gases; if I had such an instrument at my disposal, I am sure I could make it useable for testing burner or vitriol-chamber gases for SO<sub>2</sub>, and even arrange it for continuous registration of the results. But hitherto I have not been able to obtain a balance made of such material that it could be used for this purpose, and it remains to be seen whether Mr. Lux will be able to do that.

Another method for estimating the specific gravity of gases has quite recently been proposed by Friedrich C. G. Müller. It consists in passing a stream of the gas through a perpendicular tube, 4 ft. long, connected at the bottom with a sensitive pressure-gauge communicating at the other end with the atmospheric air. It stands to reason that the 4-ft. column of gas will exercise a different pressure on the pressure-gauge from that of atmospheric air, and this, by means of an empirical graduation, can be utilised for estimating the specific gravity to the third decimal. After prolonged correspondence with the inventor, concerning the application of this ingenious method to the testing of burner gases, I have come to the result that this should be possible, but so far I have found no time to work out a practical method and apparatus for this purpose.

## 3.—TESTING OF THE CHAMBER EXIT GASES.

The testing of the exit gases from vitriol chambers is decidedly capable of improvement in some particulars. In the first instance the well-known prescriptions of the English Alkali Makers' Association can be greatly simplified by introducing the above described process with caustic acid and phenolphthaleïn, and this has been already done with great practical success.

But I found it also necessary to revise the methods for estimating the *nitric oxide* in the exit gases, since many experiences point to the fact that far greater losses arise from this source than had been hitherto assumed.

For this purpose it was indispensable, first, to compare the different descriptions of absorbing apparatus in use, and select the best of them; secondly, to see whether any more accurate method than that employed—potassium permanganate as an absorbent for NO—could be found. I will here give only the general results of this investigation, in which I have been very ably assisted by Mr. Marchlewski.

*Concerning the best shape of absorbing apparatus.*—I excluded at once from our research the simple and rough forms, as well as those adapted only for re-weighing, but not for re-titration, such as Liebig's potash-bulbs. The

apparatus experimentally compared were: first, Mitscherlich's tubes, Fig. 2; second, Pettenkofer's tubes, as modified by myself, Fig. 3; third, Winkler's glass worms, which are

equally to be considered as modified Pettenkofer tubes; fourth, glass-bead tubes, Fig. 4; fifth, bulb tubes with 10 bulbs, of the shape shown in Fig. 5.

Fig. 1.

Fig. 3.

Fig. 4.

Fig. 6.

Fig. 2.

Fig. 5.

If the Mitscherlich tubes, we always placed three in succession, of the other apparatus two, and made a large number of experiments with all of them with the following results. The Mitscherlich tubes are most imperfect, even three of them in succession do not secure a complete absorption of the nitric oxide from a 1 per cent. mixture of that gas with 100 vols.  $\text{CO}_2$ . Since the tubes known as "Todd's tubes" are but slightly modified Mitscherlich bulbs, similar results must be looked for in their case. Much better was the absorption with the Pettenkofer-Lunge tube, indeed, decidedly superior to Winkler's glass worms, but even here a single apparatus did not retain all the  $\text{NO}$  from a 1 per cent. mixture. This was, however, the case both with the glass-bead tube, Fig. 4, and the ten-bulb tube, Fig. 5, one of which sufficed for completely absorbing the  $\text{NO}$  from a 1 per cent. mixture with  $\text{CO}_2$ . Of these two apparatus I ultimately decided for the ten-bulb tube, which for greater security may be enlarged to fifteen bulbs, because it is easier to employ and completely wash it for re-titration.

My research further extended to the question whether potassium permanganate could be replaced by a better absorbent for nitric oxide. Permanganate has the drawback that even strongly acid solutions, on passing the gases through, especially when hot, gives a precipitate of hydrated manganese dioxide. This causes no inaccuracy in testing if the tube is rinsed with part of the ferrous sulphate solution employed in re-titrating, when the precipitate will easily dissolve; the final result is exactly the same as in such cases where no manganese dioxide had been precipitated. But this precipitation is always a little inconvenient, and an absorbent free from this drawback would be, no doubt, preferred to potassium permanganate, especially if it were more sensitive than that reagent is to nitric oxide.

Hydrogen peroxide has been several times proposed for absorbing nitric oxide, and we thoroughly examined it in that respect, but it does not seem worth while to give any details of our experiments, for the result was most decisive. Hydrogen peroxide, both in an acid and an alkaline solution, is a bad absorbent for nitric oxide, and altogether to be rejected for the estimation of that substance.

Many years ago I had tried another kind of absorbent for nitric oxide, viz., concentrated nitric acid, or a mixture of this with strong sulphuric acid. This retains the nitric oxide by the formation of nitrous acid, which can then be estimated by means of potassium permanganate or by the nitrometer. As the stream of gases carries away a good deal of nitric acid, we must retain this by a solution of caustic potash or soda. We have now subjected this method to a thorough investigation, with the following result: The method is much better than absorption by hydrogen peroxide, but it is decidedly inferior to the use of potassium permanganate, both in point of accuracy and in that of speed and convenience of execution.

The final conclusion of that research was: *That, so far, no better mode of estimating the nitric acid contained in chamber exit gases is known than that of passing them through a titrated solution of potassium permanganate, strongly acidified with sulphuric acid, and contained in a 15-bulb tube. At the end of the operation an excess of titrated solution of ferrous sulphate is added, and the operation brought to an end by re-titrating with standard permanganate.*

I may be permitted to state on this occasion that for standardising a solution of potassium permanganate, as well as for the testing of manganese ore and bleaching powder, the gas-volumetric methods worked out by me, and founded on the use of hydrogen peroxide, offer great

convenience and saving of time, and are at all events most useful in checking the ordinary methods. It is hardly necessary to point out in what extraordinary degree all such methods are facilitated by the use of my *gas-volumeter*, which permits reading off the volumes of gases as corrected for temperature, pressure, and moisture, without any calculation or any observations of thermometer and barometer. This is equally the case with the nitrometric operations proper, for which I have constructed a special "reaction-vessel" (this Journal, 1890, 548), greatly facilitating and expediting the analysis of *nitrous vitriol*, *nitrate of soda*, and so forth.

#### 4.—SPECIFIC GRAVITY TABLES FOR SULPHURIC ACID.

New tables of the specific gravities of sulphuric acid of various strengths have been worked out with the greatest care by myself in conjunction with Mr. Isler, and have been reprinted in the Society's Journal, 1890, 501. Similar work is to be done for nitric and hydrochloric acids, but so far the considerable time required for it has not yet been found.

Soon after the first publication of our memoir there appeared in the Journal of the Chemical Society (vol. 57, 61—185), an extremely elaborate paper by Professor Pickering on the same subject; and Mr. H. D. Richmond has founded upon this a table of the specific gravities of concentrated sulphuric acid (this Journal, 1890, 479). Professor Pickering's results are not unessentially different from ours, and the enormous amount of his observations, and the seemingly stupendous accuracy of those, indicating *thousandths* of a per cent. of  $\text{H}_2\text{SO}_4$  in the acid, may possibly make them appear more trustworthy than ours to those who have not worked in the same field. But I cannot for one moment acknowledge this conclusion. Hundreds of tests made by myself with the greatest possible care, with calibrated vessels and corrected weights, with constant checkings and re-checkings, have proved to me that estimations of strong sulphuric acid are already *very* good, if they do not deviate from one another more than by one unit in the first decimal per cent., and that the *utmost* accuracy attainable, but most certainly not attained by the great majority of workers, is  $\pm 0.05$  per cent. If, therefore Professor Pickering maintains (loc. cit. 73) that his percentages are accurate to  $\pm 0.001$ , this *impossible* assertion is in my mind from the outset a reason for distrusting the accuracy of his figures altogether, and I believe that this impression will be conveyed to others as well who take the trouble of looking at the very tottering foundation of that seemingly stupendous accuracy. All his hundreds of observations are founded upon the analysis of a sample of pure sulphuric acid, supplied by Dr. Messel, from which all other strengths were prepared by adding weighed quantities of water, without any further analyses. The fundamental analyses were not made by Professor Pickering himself, but by Mr. Crompton, and no special description is made of the methods used, except that the estimations were made volumetrically, starting from pure silver. Now those estimations of Mr. Crompton's vary between 99.704 and 99.962 per cent., that is to the amount of 0.26 per cent., and yet Professor Pickering does not hesitate to assert that the percentage of his acids, made from the fundamental acid analysed by Mr. Crompton by way of dilution, and consequently unavoidably introducing some fresh errors, however slight, are accurately known to the third decimal per cent. It is simply impossible to admit the justice of this claim, but with it falls to the ground any claim to the superiority of his results over mine.

#### 5.—SODA MANUFACTURE.

The stimulus for working out the following methods was afforded by a suggestion on the part of Dr. Hurter, who pointed out that analytical methods for the purposes in question, adapted to the requirements of a works laboratory, were very desirable.

(a.) *Estimation of Free Lime in Black-Ash.*—It is well known that a certain quantity of free lime ought to exist in black-ash, in order to facilitate the lixiviating process. I

have found that the following process, an adaptation of a plan proposed by Winkler for the analysis of quicklime, yields very good results.

The sample of black-ash is treated in the ordinary manner, as prescribed in the "Pocket Book," for obtaining a solution; that is, 50 grms. are quickly, but thoroughly, ground up to a fine powder, which is put into a litre flask and covered with tepid distilled water, *freed from carbon dioxide by boiling*. The mixture is at once well shaken up, and the agitation is several times repeated during two hours. Without such speedy and thorough shaking, a hard cake is formed at the bottom which does not any more disintegrate. After two hours the flask is filled up to the mark, and special samples are taken out for the single tests. First of all the tests are made for free lime and, if required, for total lime (see below), and for these the contents of the flask are thoroughly shaken up each time before taking out a sample. When this has been done, the flask is allowed to rest and after settling the clear part of the contents is used for the ordinary black-ash tests. The samples intended for the estimation of free or of total lime are taken out with a pipette of the form shown in Fig. 6, which is not so easily stopped up by the muddy residue as the ordinary pipettes, with a long thin outlet tube. After taking out the sample, the outwardly adhering mud is washed off, the contents of the pipette are run into a beaker, the pipette is rinsed into the same, an excess of barium chloride solution is run in, a drop of phenolphthalein solution is added, and the liquid is titrated in the cold with one-fifth-normal oxalic acid till the pink colour has just disappeared. If care has been taken to thoroughly shake up the flask before each sample is taken out, the results agree perfectly well. By this method only the free lime is found, as the oxalic acid acts upon the carbonates only after saturating the free lime, and, when doing so and setting some  $\text{CO}_2$  at liberty, the red colour is discharged at once.

A special set of tests were made by adding a quantity of neutral cane-sugar solution, in order to see whether more lime would thus be indicated, owing to its solubility in that solution; but the results entirely agreed with the former ones, so that the sugar can be dispensed with.

(b.) *Estimation of Total Soda and Total Lime in Black-Ash.*—This estimation is desirable because it is a check on the proper mixing of the black-ash. Unfortunately, the most accurate methods for this purpose would not be of very much practical use, because the difficulty of getting a really representative average sample of a black-ash ball is almost insuperable, as Dr. Hurter has found in an extensive series of trials. All the more expeditious methods are in their place here.

As it is, at most works the soda contained in the solution of black-ash in the shape of  $\text{Na}_2\text{CO}_3$ ,  $\text{NaOH}$ ,  $\text{Na}_2\text{S}$  and  $\text{Na}_2\text{SO}_4$  is generally estimated, and the result is best reduced for our purpose to  $\text{Na}_2\text{SO}_4$ . The soda present in other soluble forms or in the insoluble state need not be taken into account, or else a certain quantity is allowed for it once for all. We shall thus get the *total soda*, and we have only to make a special test for *total lime*, which we do as follows:—Together with the samples taken out of free lime, we take out two or three samples of the well-agitated *muddy* liquid for our present purpose, exactly in the same way as prescribed above. Each sample is put into an Erlenmeyer flask, mixed with a few cc. of strong hydrochloric acid and boiled till all the gases have been expelled. A drop of methyl-orange is now added, and sodium carbonate solution is run in till the pink colour has just disappeared. Now 30 cc. of one-fifth-normal sodium carbonate solution is run in from a burette and the liquid is once more boiled to precipitate all  $\text{CaCO}_3$ . The small quantity of ferric oxide, alumina, magnesia, &c. equally precipitated, can be neglected here.

The liquid is washed into a 200 cc. flask, which is filled up to the mark, and 100 cc. of the clear portion is titrated with one-fifth-normal hydrochloric acid to find out the quantity of  $\text{Na}_2\text{CO}_3$  taken up by the lime present.

In four tests according to this method made by my assistant, Mr. Werner, the following quantities of one-fifth-normal acid were used (upon 30 cc. of sodium carbonate

solution):  $16.5 - 16.5 - 16.6 - 16.5$ , corresponding to  $30 - 16.5 = 13.5$   $\text{Na}_2\text{CO}_3$  used up =  $0.135$  gm.  $\text{CaCO}_3$ .

Only after all the samples intended for the tests (a) and (b) have been taken out, the original black-ash solution is allowed to settle down, and the samples for the estimations of sodium compounds are taken now. In the last-mentioned case the clear solution showed a litre of  $9.2 - 9.25 - 9.2$  cc. one-fifth-normal acid, equal to  $0.0975$   $\text{Na}_2\text{CO}_3$ , or originally  $0.130$   $\text{Na}_2\text{SO}_4$ , to which should be added the  $\text{Na}_2\text{SO}_4$  present as such, but not indicated by titration.

(c.) *Estimation of Available Soda in Alkali Waste.*—In alkali waste there is, apart from soda occurring in the insoluble form (which is but rarely estimated), always some soda present in a soluble shape; at the same time also, owing to the prolonged action of warm water on calcium sulphide, some calcium sulphhydrate or other soluble calcium compounds. Certainly such soluble compounds of calcium cannot exist at the same time with sodium carbonate; in presence of water they will interact and calcium carbonate will be precipitated, whilst sodium sulphhydrate, &c. will enter into solution. In the case of old alkali waste mud, calcium sulphhydrate, polysulphide, and thiosulphate will be in solution as well; even in the case of fresh waste possibly such calcium compounds, partially acting upon acids, may be in solution at the same time with sodium compounds indicated by acids, whilst on the other hand badly lixiviated waste will yield a solution containing an excess of  $\text{Na}_2\text{CO}_3$ , and consequently no soluble calcium salts at all.

These facts have been known all along, and it was always notorious that direct titration of an aqueous extract of alkali waste leads to entirely erroneous results. I have proved this directly in the "Chemische Industrie," 1881, 372, and in consequence of this a process was received into the "Pocket Book," consisting in evaporating the aqueous extract to dryness with addition of a little ammonium carbonate, igniting the residue, treating it with water and titrating the clear solution. This process is somewhat lengthy; what is worse, it is inaccurate, as pointed out to me by Dr. Hurter. The reason is probably that during evaporation some of the sodium sulphide is oxidised into thiosulphate, which of course escapes notice in the titration. Dr. Hurter communicated to me the method used at some Lancashire works, and consisting in treating the aqueous extract with carbonic acid, boiling the solution to decompose the calcium carbonate, and filtering and titrating the clear solution. I have examined this method with the following results (obtained by Mr. Zalscecki):—

Total alkalinity of the aqueous extract ( $\text{Na}_2\text{O} + \text{CaO}$ ) =  
 $45.3$  cc. one-fifth-normal acid.  
 $45.15$  " "  
 $45.2$  " "

After one hour's treatment with gaseous  $\text{CO}_2$  (less is not sufficient), boiling and filtering:—

$26.0$  cc. one-fifth-normal acid.  
 $26.2$  " "  
 $26.3$  " "  
 $26.15$  " "

After quarter of an hour's boiling with zinc carbonate and filtering:—

$26.1$  cc. of acid.  
 $25.95$  "  
 $26.05$  "  
 $26.5$  "

Hence the  $\text{CO}_2$  method yields quite consonant results, practically identical with those obtained even more quickly by zinc carbonate. Neither of these methods will yield absolutely true results, but such as suffice for purposes of comparing working results. The difficulty of getting a really average sample of waste is certainly one which can be hardly overcome.

(d.) *Estimation of the Available Soda in Commercial Caustic Soda.*—It is well known that caustic soda contains several sodium compounds which saturate acid on testing, and are hence indicated as available soda, viz., sodium hydrate, carbonate, silicate, and aluminate. Where it is important that the caustic should contain as little carbonate

as possible, the  $\text{CO}_2$  is estimated and the  $\text{Na}_2\text{CO}_3$  is deducted from the total  $\text{Na}_2\text{O}$ . But there is a general, although but tacit, agreement to count the soda combined with silica and alumina as available soda, both because the quantities occurring in commercial caustic are exceedingly slight, and because the soda in these compounds is wellnigh all practical cases acts like the hydrate. This saves the somewhat tedious estimation of silica and alumina.

It does not seem as if this usage was to be attacked from any side; but Cross and Bevan (this Journal, 1889, 252) have drawn attention to the fact that when methyl-orange is employed as indicator, the test-acid saturates not merely the  $\text{Na}_2\text{O}$ , but also the  $\text{Al}_2\text{O}_3$  of the sodium aluminate, before the pink colour is produced, and this is a source of error. But apart from the fact that Cross and Bevan, as I have proved in the Zeits. f. angew. Chem. 1890, 300, erroneously contend that the change of colour takes place when the proportion  $2 \text{Al}_2\text{O}_3 : 5 \text{H}_2\text{SO}_4$  is reached (the real proportion being  $\text{Al}_2\text{O}_3 : 3 \text{H}_2\text{SO}_4$ ), I must also protest against their exaggeration of the real error pointed out by them, and their general condemnation of the use of methyl-orange for titrating caustic soda. From a large number of analyses, partly found in chemical publications, partly made by myself, I must conclude that the amount of alumina contained in ordinary commercial caustic soda is mostly quite inappreciable, and certainly never exceeds  $0.1$  per cent., so that it may be neglected in testing for alkali. The reason of this is, that in the manufacture of caustic the temperature in the end is kept so high that the compounds of soda with alumina and ferric oxide are split up again, and alumina and ferric oxide settle down at the bottom of the caustic pots. The "bottoms" are then laded out by themselves, and are mostly worked up again, but part of them is sold in that state, and as they contain about 2 per cent. of alumina, titration with methyl-orange would certainly give far too high a result. In testing caustic bottoms, therefore, methyl-orange must not be used, but otherwise there is no necessity for renouncing the use of this exceedingly convenient indicator.

#### 6.—SULPHUR RECOVERY. ESTIMATION OF SULPHURETTED HYDROGEN AND SULPHUR DIOXIDE IN THE SAME GASEOUS MIXTURE.

An analytical method for this purpose has become necessary, since in the Chance-Claus sulphur recovery process a gaseous mixture escapes containing small quantities of both  $\text{SO}_2$  and  $\text{H}_2\text{S}$ , together amounting to about 30 to 50 grms. S per cubic metre. Owing to the enormous amount of foreign gases, chiefly nitrogen, in spite of the presence of moisture no reaction ensues between  $\text{SO}_2$  and  $\text{H}_2\text{S}$ ; they must be dealt with by special absorbing apparatus, and hence also an analytical method for their estimation has become desirable.

Such a method had been devised by Mr. H. Crowther, chemist at Messrs. Chance Bros. He passes samples of the gases at the same time through solutions of hydrogen peroxide and of iodine. The former exerts the following reactions:—

That means:  $\text{SO}_2$  is converted into  $\text{H}_2\text{SO}_4$ , but  $\text{H}_2\text{S}$  does not form any acid, hence titrating the hydrogen peroxide by standard soda solution will indicate the  $\text{SO}_2$  alone.

On the other hand the reaction with iodine solution is in both cases such that each atom of S converts two atoms of I into HI:—

Thus the total sulphur is indicated, and  $\text{H}_2\text{S}$  is found by subtracting from it the S of  $\text{SO}_2$  found as above by means of  $\text{H}_2\text{O}_2$ .

Mr. Crowther's process has been introduced into all works where the Chance process is working, but complaints have reached me according to which the results are not accurate enough. In order to investigate this matter, I have, with the aid of Mr. Marchlewski, made a large number of experiments. It was found that in point of fact hydrogen peroxide

is not at all a good absorbent for  $\text{H}_2\text{S}$ , but at all events its acidity is not altered by that compound, whilst  $\text{SO}_2$  is easily and completely absorbed. This part of the process is therefore quite correct, indeed it has been employed for many years past by other chemists (especially Classen). The fault is in the other part, the estimation of total sulphur by iodine solution. We found that the gaseous current always carries away a certain quantity of iodine which makes the total sulphur and hence the  $\text{H}_2\text{S}$  to come out too high. But this can be avoided by placing behind the iodine an absorbing tube with caustic soda solution which retains the iodine, and whose contents are added to the iodine solution before re-titration. This addition then ought to be made at all events to the apparatus.

It is, however, preferable to proceed in a different manner, viz., to leave out the treatment with hydrogen peroxide, to pass the gases simply through a bulb-apparatus containing iodine solution, followed by another apparatus containing a little standard caustic soda solution. At the end of the operation the contents of both apparatus are united.

The mixture ought to possess an acid reaction; if not it is acidified with a known quantity of standard acid. The unused iodine is then estimated by means of thiosulphate; now methyl-orange is added and standard soda is run in till neutrality has been established. This process yields all data required for estimating  $\text{SO}_2$  and  $\text{H}_2\text{S}$ , since the latter liberates only its equivalent of  $\text{HI}$ , but the former, besides its equivalent of  $\text{HI}$ , also an equivalent quantity of  $\text{H}_2\text{SO}_4$ —

If we call the difference between ccm. of iodine solution originally employed and that of thiosulphate used in re-titrating =  $m$ ,—the originally employed ccm. decinormal soda solution (which must be  $< m$ ) =  $n$ , and the quantity of soda solution used in the end for establishing neutrality =  $o$ , the quantity of sulphur present is found by the following expressions:—

$$\text{S in } \text{H}_2\text{S and } \text{SO}_2 = 0.0016 \text{ } m$$

$$\text{S in } \text{SO}_2 \text{ alone} = 0.0016 (n + o - m).$$

In order to test this process practically, we passed a mixture of  $\text{SO}_2$  with very much atmospheric air through iodine and soda, as above described, and ascertained then how far the results obtained by titration coincided with those obtained by gravimetric estimation of the sulphuric acid formed.

The results were in three separate experiments:—

—	Iodometrical Process.	Gravimetric Process.	Difference.
<i>a.</i>	Grm. 0.07186	Grm. 0.0730	Grm. + 0.00114
<i>b.</i>	0.0776	0.07806	— 0.00046
<i>c.</i>	0.0799	0.06913	— 0.00077

Experiment *a* showed sufficient, *b* and *c* excellent agreement between the two methods. Hence the method now proposed, which is both more accurate and more expeditious than that formerly used, may be safely recommended to all chemists concerned.

One or other of the above mentioned absorbing methods, that is either hydrogen peroxide or iodine, can be employed in the methods proposed by Zilkowsky, Jannasch, and others, for estimating the  $\text{SO}_2$  escaping in the roasting of spent oxide of gas-works, or of pyrites itself. Those authors proposed bromine for this purpose, and estimated the sulphuric acid gravimetrically, after destroying the bromine present in excess; but the reagents now proposed save the lengthy manipulation last mentioned, and substitute a titration for a gravimetric estimation.

### SESSION 1890-91.

1891.

Jan. 5th (Glasgow).—Mr. H. Ballantyne. "On the Effect of Exposure, under Certain Conditions, upon some Constants of Oils."

Feb. 2nd (Edinburgh).—Dr. J. B. Readman. "The Manufacture of Phosphorus: Part III."

Mar. 2nd (Glasgow):—

(1.) Dr. E. J. Mills. "Destructive Distillation: Part II."

(2.) Messrs. R. T. Thomson and H. Ballantyne. "On the Revision of Constants Employed in the Analysis of Fats and Oils: Part II."

Meeting held in the Societies' Rooms, 207, Bath Street, Glasgow, on Monday, November 3rd, 1890.

MR. C. A. FAWSITT IN THE CHAIR.

THE CHAIRMAN said he was sorry to inform the members that their Chairman, Mr. Stanford, had been ordered abroad through ill-health, and would not be able to take any share in the work of the Society for some time. He was sure they were all very sorry at this circumstance, and would unite with him in the desire that the time was not far distant when Mr. Stanford would be able to return home restored to health.

At the beginning of another session he would remind them that the success of the meetings depended upon the members themselves. He hoped they would vie with each other in producing papers of merit, and not only so, but that they would influence their friends, whether members of the Society or not, to come forward and read papers. One part of the meetings, of which he would like to see more advantage taken, was the discussion. Although the paper contributed was ever so valuable few remarks were elicited. This he hoped would be remedied in part at least, by the removal of the meeting place to this smaller room, where they would feel more at home. Regarding the night of meeting, it had been changed from Tuesday to Monday, the latter being considered the most suitable.

## A MECHANICAL RETORT WITH CONTINUOUS FEED AND DISCHARGE.

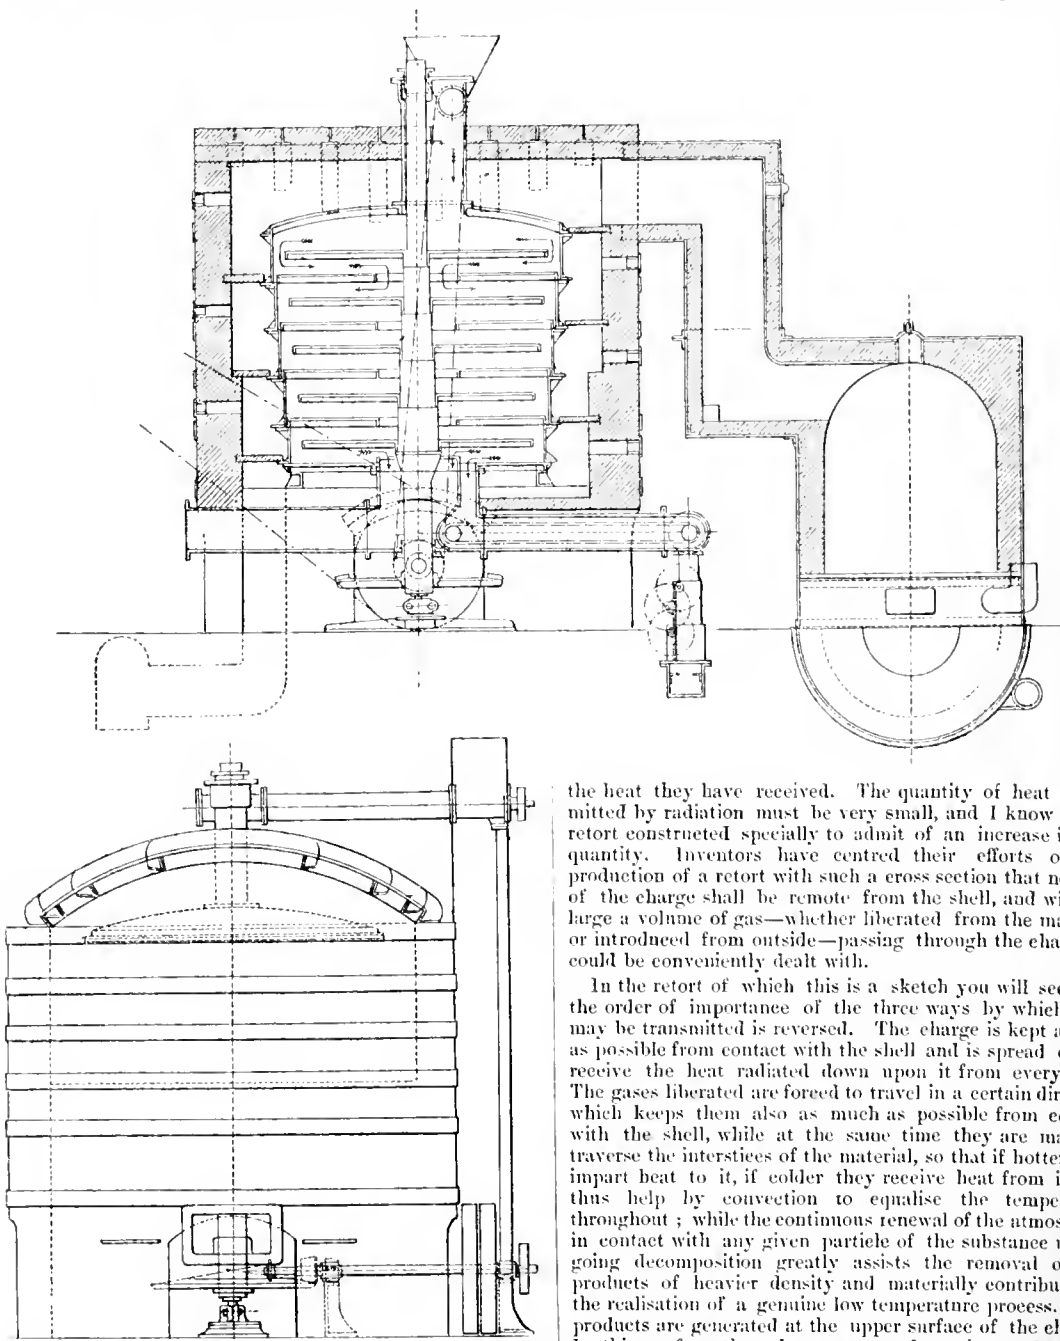

BY R. HAIG.

THIS retort, the patent of which belongs to the Mechanical Retorts Company, Limited, of Paisley, possesses, apart from its mechanical principle, a feature which should, I think, render it interesting to you from a scientific point of view. I refer to the manner in which it utilises the heat supplied to it.

A retort, in the ordinary conception of the term, is a vessel usually much longer than broad, and which may have its length disposed in a vertical, inclined, or horizontal

direction. The cross section may be round, square, -shaped, or oval. A furnace heats the outside, and the charge more or less completely occupies the inside. Heat passes by conduction through the shell of the retort to the contents, and upon the texture of these as well as on the temperature of the fire depends in a great measure the rapidity with which the charge is worked off.

The substances distilled are of low conductivity, and if they are charged into the retort in a state of fine division, or if they crumble during the distillation, the heat takes much longer to penetrate to the centre of the charge than when, owing to the state of coarser division of the material, there is more interstitial space. This, I think, is owing to the fact

the heat they have received. The quantity of heat transmitted by radiation must be very small, and I know of no retort constructed specially to admit of an increase in this quantity. Inventors have centred their efforts on the production of a retort with such a cross section that no part of the charge shall be remote from the shell, and with as large a volume of gas—whether liberated from the material or introduced from outside—passing through the charge as could be conveniently dealt with.

In the retort of which this is a sketch you will see that the order of importance of the three ways by which heat may be transmitted is reversed. The charge is kept as free as possible from contact with the shell and is spread out to receive the heat radiated down upon it from every side. The gases liberated are forced to travel in a certain direction which keeps them also as much as possible from contact with the shell, while at the same time they are made to traverse the interstices of the material, so that if hotter they impart heat to it, if colder they receive heat from it, and thus help by convection to equalise the temperature throughout; while the continuous renewal of the atmosphere in contact with any given particle of the substance undergoing decomposition greatly assists the removal of the products of heavier density and materially contributes to the realisation of a genuine low temperature process. The products are generated at the upper surface of the charge; by this surface they also escape, and are in no danger of having to penetrate a mass of material much hotter than themselves, as would be the case with gases generated in the middle of a charge heated by conduction from all round.

that in the latter case the gases evolved from that portion of the charge adjacent to the hot shell are free to travel throughout the rest of the mass, and by convection distribute

It is only during, say one-tenth of the period of distillation that the charge is in contact with a part of the shell directly heated by the furnace gases, and those furnace gases are at this point on their way to the chimney, and being almost spent can impart but little heat, while the charge having finished nine-tenths of its course through the higher or radiation-heating part of the retort is almost completely decomposed and in the condition least suitable for absorbing conduction heat; it may therefore be said that this plays no part in the distillation effected by our retort.

I think the idea of a mechanical retort probably first suggested itself to someone who distilled small materials, and who found the strain on the shell of the retort, owing to the high temperature at the end of an operation, very destructive.

It was natural to suppose that some arrangement by which the charge could be stirred up and each particle brought in its turn within the influence of the heated shell would obviate this disadvantage. With some materials the difficulties to be overcome were not very serious, and there are many retorts with mechanism inside or outside of them, which appears very simple and little likely to be deranged by the heat, which have been patented; yet when it came to treating a substance difficult of manipulation when hot and of a delicate constitution chemically, the users of those retorts appear to have lost confidence in them.

I have seen a horizontal cylindrical retort, capable of being rotated about its axis and consequently with all its mechanism outside, which, after a dozen charges had a skin of coke three or four inches thick adhering to the inside of the shell, caused not by the decomposition of gaseous hydrocarbons like the carbon coke in a gas retort, but by the crumbling and melting of the substance with which it was charged, and which was deposited layer by layer as the retort revolved. As this deposit increased in thickness the fire required to be urged, the distillate was less good, more coal was burned, the time to exhaust a charge greatly increased, and the chipping which was done after a thorough cool down was effected with considerable difficulty.

If this retort had been fitted with internal mechanism of the ordinary screw or chain type the result would not have been greatly different, and I think the defect lies in allowing the substance to rest on a surface heated from underneath by the furnace, so that decomposition begins below, and the superincumbent charge increases the tendency to adhere not only by its weight but also by preventing the free evolution of the vapours.

Our retort, as you see by the drawing, consists of a vertical cylinder, with a diameter of eight feet at the bottom, which is increased by three inches at regular intervals till it is nine feet wide at the top and seven feet six inches high. Both top and bottom are closed by discs, each having a large hole at the centre. Projecting upwards from the top disc and downwards from the bottom disc are sleeves which pass through the flues and brickwork to the open air, and which are fitted at their extreme ends with stuffing glands, in which the centre shaft, driven from below by gearing, revolves. The sleeves are much wider than is necessary for the passage of this shaft. It is through the upper one that the substance to be distilled is charged, the products being removed by the lower one. The centre shaft, like the shell, is also stepped, but instead of increasing towards the upper end it diminishes in diameter. The steps or shoulders are arranged at different levels from those on the shell, so that the discs which rest on them are exactly midway between those which rest on the shell. The discs rest alternately on the shaft and on the shell; those on the shaft revolve with it, those on the shell are stationary. The discs on the shaft do not quite reach to the shell, but are smaller in diameter by about a foot, the discs on the shell have an opening in their centres leaving an annular space round the shaft. From snugs cast on the under side of each plate are hung scrapers or deflectors which act like ploughs. Those hung from a fixed disc but working on a revolving disc, face towards the shell. Those hung from a revolving disc but working on a fixed disc, face towards the shaft. All are arranged to deflect the material on the respective discs, outwards from the shaft

and inwards from the shell. The material is put into the hopper on top either from hutchies on an over-head railway or by means of a bucket elevator from the ground, and is thence forced by a screw to the branch on the upper sleeve; here it falls down alongside the shaft on to a moving plate near its centre. As this plate moves slowly round the material forms a ring upon it. This ring is interrupted by a deflector hung from the top cover which pushes the material aside as fast as it comes round, and makes a larger ring while another small ring is being laid down. The large ring is again expanded into one still larger by another deflector, and so on till the outermost deflector pushes it over the edge of the disc on to the fixed disc below. As this deflector is itself fixed, the material falls on to the fixed disc at a fixed spot, and if left alone would pile up there, but certain deflectors hung from the edge of the moving disc and which (for simplicity, I will say) do not quite reach down to the fixed disc, are continually knocking the top off this heap and extending the material in a ribbon close to the shell. Here rings continue to be formed as before, but each succeeding one is lessened in diameter by a deflector hung from a moving disc, till all the material is pushed over the edge of the opening in the middle of the fixed disc. Here it arrives on the centre of a moving plate as at the first, and the cycle of movements outwards and inwards is repeated with each pair of discs till the material arrives at the bottom of the retort. It then falls down a shoot in the bottom sleeve to the chain conveyor, and is carried out over the large bevel wheel to the double valve apparatus by which it is discharged into a waggon or otherwise removed.

By the arrangement of deflectors described, you will notice that the whole charge is not kept in continual motion, but that only a little of it is being moved at any one time. Less power is therefore necessary for driving, and the deflectors move out of the way and leave the newly turned up substance fully exposed. The vapours generated or liberated travel in the same direction as the material, and pass to the condenser by the larger opening in the bottom sleeve. The heat, which may be supplied by a gas producer or furnace, according as one or other is suitable for burning the coal of the district, is first applied to the top of the retort, which is covered by an arch of special construction, and from thence passes by a zigzag course on both sides of the retort to the bottom, below which the flue gases escape to the chimney. You see that where the fire is hottest, the cold material is introduced, and when the material begins to decompose, the flue temperature is moderated, but always remains hotter than the material, and imparts heat to it. This might not, at first sight, appear a good arrangement for ensuring economy in coal consumption, for the flue gases, being above the decomposing temperature of the charge, convey a lot of heat to the chimney which might be used up in warming a fresh quantity of material to the distilling point; but it must be remembered that with the travel of the generated gases arranged as described, the temperature of volatilisation of the heavier products is lowered undoubtedly, and it is possible that that of decomposition may, by the favouring conditions, be so as well; so that, though the hottest fire were applied below the retort, and the flue gases more thoroughly cooled by passing over the cold material above, it is doubtful if any economy would be gained, and it is certain that the equality of temperature at present existing, and which is valuable, would be lost. The number of discs may be varied to suit the nature of the substance to be distilled, but I think need not exceed 12.

The retort at present in use at our Paisley works has only eight plates, and on a consumption of less than  $2\frac{1}{4}$  cwt. of coal per ton of wood, puts through an average quantity of 12 tons per day of 21 hours. The wood is principally birch in the form of shavings from the bobbin makers. The retort represented by the sketch in your hands was sent abroad to distil shale; it has 10 plates, and also puts through 12 tons per day, but the coal used, which was of very poor quality, amounted to about 4 cwt. on the ton of shale; with Scotch coal I am sure this figure would be much lower.

The shell of the retort is made of cast iron 1 in. thick, and the discs, which are strengthened by ribs cast on their

underside, have a thickness of  $\frac{3}{4}$  of an inch, the total weight of an eight-plate machine is about 20 tons, and the machine work necessary is trifling. The brickwork is simple, but I would like to draw your attention to the vault on the top, which is made so as to throw no strain on the side walls. Fireclay blocks with a cheek at each end are built into a "tee" iron curved to the circle of the outside of the vault and turned in at the ends, so that when the whole is lifted by a muzzle bolted to the web of the "tee" iron the bricks retain their position. Eight or ten of those arches of varying length when placed side by side cover the whole of the retort, and as the irons are not exposed to heat they bind the structure very firmly.

I regret I have been unable to show you a sketch embodying our most recent improvements, but the tracing handed round shows plainly the theoretical principles on which we work. The improvements I refer to are merely in the construction and enable us to have the castings made more cheaply. We now have the fixed and moving discs respectively made of one diameter, so that when shipped abroad one spare disc of each kind may be sent as a precaution against accident.

The discharging apparatus at the bottom of the retort is also simplified.

That the theory upon which the construction of the machine is based is a correct one is proved, not only by the small amount of coal used, but also by the excellent quality of the distillate produced. The wood used at our works, which, I believe, is stoved-dried before being cut up, can contain no superfluous moisture to increase the quantity of distillate, and this quantity, which amounts to 140 galls. per ton is, as far as I have been able to find out, much greater than that produced from air-dried billets commonly used in fixed retorts. The specific gravity of the liquor after settling is about 1.09 or 1.8 Tw., showing that it contains much hydrocarbon matter; it shows by test between 13 and 14 per cent. of glacial acetic acid. The yield of charcoal is 4 cwt., and the amount lost by difference as incondensable gas is only 2 cwt.

The retort which treated shale produced a full yield of oil of an excellent quality, much better than that from fixed retorts. The exhaust steam from the engine which drove it was, without being superheated, passed into this retort.

The power required for driving is very little, and by calculation from the breadth and speed of the belts amounts to three-horse power for the wood retort and five for the shale one.

We have treated two or three tons of seaweed with our machine and the iodine left in the residue was greatly in excess of that usually found. The quantity unfortunately was too small to afford a test of the capacity of the retort for this purpose.

#### DISCUSSION.

The CHAIRMAN said that the wood-distilling industry was one of great importance, and a paper connected with the subject was very acceptable. This industry had suffered much in recent years by competition from America and Germany. The Americans distilled an immense quantity of wood—mainly for the charcoal—and sent to this country acetate of lime and wood-spirit in such quantities as to make their manufacture here unremunerative. This retort, however, seemed as if it would help manufacturers to produce these articles more cheaply than could be done by the other retorts in use. If this was so, it would supply a want long felt by wood distillers. There was also a wide field before it for distilling shale, if it distilled economically, and the wear and tear were not excessive.

As far as he remembered, the original patent was in the name of a Mr. Lyle. Would Mr. Haig say whether this retort is a modification of that one or a new patent altogether? The wear and tear of these retorts had always appeared very heavy, and it would be an advantage if Mr. Haig could tell them what was the amount per ton of wood distilled. He should like to ask also what was the size of the shale treated, and how the temperature of this retort compared with that of the stationary retorts? Then he should like to know, too, what was the percentage of acetic acid, wood spirit, tar, &c. as compared with that which comes from other retorts?

Mr. Brown asked if Mr. Haig had ever tried this retort on alkaline liquors, and if not, how he thought it would do for that purpose?

M. J. PATTISON asked if the products contained more tar than those obtained by the old process, and if the quality of the charcoal produced was as good as, or better, than by the old one?

Dr. G. G. HENDERSON said that, with regard to the temperature of the retort, he gathered that the upper part was at a much higher temperature than the lower part. Could Mr. Haig give them the average difference of temperature between the upper and lower parts, and also could he inform them whether any experiments had been made as to the effect of varying differences of temperature between the top and bottom of the retort? He would also like to know if Mr. Haig could inform them as to the different percentage of the various products obtained at different temperatures, as compared with the ordinary retorts?

Mr. R. HAIG, in reply, said that at first the retort had been very difficult to work, though the actual wear of moving parts was nil. The trouble was caused by the faulty construction of the shell, which began to leak after a few months' work. This was now entirely obviated by having it made in rings instead of segments, so that no strains were thrown on the joints. With a tight shell there is no danger of anything going wrong.

The shale referred to was broken to the usual size for road metal.

The liquor produced from wood contained 13–14 per cent. of glacial acetic acid, which was allowed to be a very good yield.

The retort had never been tried for recovering waste soda lyes of paper makers, but if these were first concentrated to a proper consistency, it would certainly carbonise the organic matter they contained, and the soda might be lixiviated out of the residue. It would no doubt be an advantage to have the organic matter destroyed without exposing the soda to the sulphurous gases of the furnace.

The charcoal is discharged from the retort the moment it is spent, and, being produced at a low temperature, is very suitable for gunpowder making. Much of it is used for insulating the refrigerating chambers in which meat is brought to this country and stored on arrival; it is very light, and is unaffected by damp or dry rot. It is chiefly produced from birch, and this is known to yield more tar than some hard woods, but the retort produces so much more liquor per ton than is got by the old way that a slight increase in the tar which settles out is immaterial.

The question about the difference in results got by varying the difference of temperature which exists between the top and bottom of the mechanical retort was probably suggested to Dr. Henderson by the known arrangement of Young and Beilby's retort, which has practically two chambers, one kept at a higher temperature than the other, the one producing ammonia and the other oil, two distinct chemical operations. The retort described to-night, although to a certain extent divided by the discs, acts as a single chamber at a uniform temperature, but this temperature may be varied over all to suit the nature of the decomposition required. Wood and shale, which are worked for the distillates, require a low temperature, which is ensured by feeding the material thickly into the retort. The effect of a higher temperature may be readily shown by driving the retort faster and the feed slower, so that the charge passes through in a thin stream. Neither shale oil nor pyroigneous acid produced under such conditions is as good as that made in the first method of working, but it is conceivable that some substances might do better with a somewhat high temperature. The usual practice is to have redness just visible in the second flue from the top. The actual temperatures of the evolved or flue gases have not been measured, but it is possible to preserve great uniformity in these by changing the speed of the engine which drives the retort to suit variations in the condition of the fire.

## Obituary.

### EDWARD CHAMBERS NICHOLSON, F.C.S.

A MEMBER OF THE SOCIETY OF CHEMICAL INDUSTRY.

In the year 1845 the Royal College of Chemistry had been but comparatively recently founded by Professor A. W. Hofmann. In that year two of the Professor's first students were appointed by him to assist him in the pursuit of his earlier brilliant researches in organic chemistry. One of these was Edward Chambers Nicholson, the other was Frederick Augustus Abel, now Sir Frederick Abel. After a few years Nicholson became associated with the conduct of a small chemical manufacturing business, which, under his guidance and chemical supervision, speedily developed, and at length acquired, through his work, a very high reputation for the production of rare chemical compounds upon a manufacturing scale. Directly after the foundation to the coal-tar colour industry had been laid by the discoveries of W. H. Perkin, Nicholson produced upon a large scale and of a high degree of purity certain tinctorial coal-tar derivatives which speedily acquired great commercial importance, and thus brought fame as well as profit to his firm. Turning now to a series of lectures on "Coal-tar colours and on recent improvements and progress in dyeing and calico printing, embodying copious notes taken at the International Exhibition of 1862," by the late Dr. E. Crace Calvert, delivered in Manchester, we read "Most persons must have admired in the recent exhibition the beautiful crowns of acetate of rosaniline exhibited by Messrs. Simpson, Maule, and Nicholson, which presented in reflected light the green metallic lustre of cantharides' wings." Also further on we read "Roseine was first introduced into the trade early in 1860 by Messrs. Simpson, Maule, and Nicholson." Dr. Calvert later on refers to the once much-used "*Bleu de Lyon*," at first largely imported into this country, but, adds Calvert, "now manufactured by Messrs. Simpson, Maule, and Nicholson." It is indeed refreshing to note throughout the lectures how, through the influence of this great technological chemist, the firm, which he was raising to a position of eminence, not to speak of affluence, held its own, and more than held its own in the race with the best continental firms representing the coal-tar colour industry.

After a career as manufacturing chemist as brief as it was brilliant, Mr. Nicholson retired from business, and it has been a source of much regret to those acquainted with his exceptional powers as an investigator and originator of manufacturing processes, that he thought best to abandon the active pursuit of chemical science in the full tide of success, and when his continued labours could not have failed to be of important benefit to the chemical industries.

Edward Chambers Nicholson died on the 23rd of October last, after a brief illness, at the age of 63 years. It is not too much to say that to his remarkable talent for developing into successful manufacturing processes, intricate laboratory methods for the preparation of new and rare products, England chiefly owed the high position she held in the industrial world in the early days of the coal-tar colour industry. Nor should, in this connexion, the scientific enthusiasm or inspiration be forgotten, due to the teachings and ennobling influence of that master of scientific instruction and original investigation, A. W. Hofmann, an influence both felt and responded to by so many of his pupils during his directorship of the Royal College of Chemistry and subsequently in their later careers.—W. S.

## Journal and Patent\* Literature.

### I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

*Lubricating Oils.* A. C. J. Charlier. The Engineer, 1890, 305—306.

See under XII., page 1043.

#### PATENTS.

*Improvements in Filters.* G. MacDonald, London. Eng. Pat. 14,972, September 6, 1889. 8d.

In this invention the filtering medium in the form of a compressed block is enclosed in a receptacle open at the top and perforated at the bottom, and is covered by a cap or bell, an annular space being left between the bell-cover and the receptacle. A connected series of these receptacles is placed in a portable vessel or cistern. The water to be filtered rises in the annular space, and flowing over the rim of the receptacle, passes through the filtering medium and perforated bottom, which communicates with the outlet pipe. By preference, the filtering medium is the "carbide material" described in Eng. Pat. 18,177 of 1888, and known as magnetic oxide of iron. Several modifications of the apparatus are shown on the drawing accompanying the specification.—E. S.

*An Improved Cooling Apparatus for Brewing and Domestic Purposes.* C. Huelser. From N. Reif, Hanover, Germany. Eng. Pat. 16,079, October 12, 1889. 8d.

See under XVII., page 1056.

*Improvements in Apparatus for Distilling and Concentrating Solutions.* J. Price, Liverpool. Eng. Pat. 16,520, October 19, 1889. 8d.

THE object is to construct the apparatus used in distillation and concentration so as to obtain the desired effects with great economy of fuel, and with little or no deposit of solid matter on the evaporating surfaces, and is effected by securing rapid flow of the liquid and maintaining it in contact with the heating surfaces. This is done by using metallic heating-tubes containing other tubes of non-conducting material, and having between the two tubes deflecting plates arranged preferably in a spiral form with an uniform or increasing pitch, so as to cause the liquid to flow continually in contact with the heating surfaces. The liquid to be treated is made to flow through the central tube, to return through the space between the two tubes (or *vice versa*). Suitable connections are fitted for the admission of the heating medium—for the liquid to be treated—for its transference to and from the several vessels, and also for the removal of the condensed water.—E. S.

*Improvements in Apparatus for Heating, Evaporating, and Condensing, applicable as a Feed-water Heater, a Distiller, or a Condenser.* W. W. Bengough, Forest Gate. Eng. Pat. 18,324, November 16, 1889. 11d.

THE apparatus belongs to that class where steam, used for heating and other purposes, is caused to pass through coiled pipes arranged within a suitable vessel, provided with inlet

\* Any of these specifications may be obtained by post, by remitting the cost price, plus postage, to Mr. H. Reader Luck, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C. The amount of postage may be calculated as follows:—

If the price does not exceed 8d. ....	1d.
Above 8d., and not exceeding 1s. 6d. ....	1d.
" 1s. 6d., " " 2s. 4d. ....	1½d.
" 2s. 4d., " " 3s. 4d. ....	2d.

and outlet branches. In this invention, one or more sections of coiled pipe are used, each in the form of a double volute. The two volute coils of each section are in one piece, and may be made of solid-drawn copper tubing. Where several sections are employed, the outer ends of the uppermost and lowermost section are placed in connexion with steam inlet and outlet pipes. By this construction a large heating or cooling surface can be provided in a small space. The coiled pipe is arranged in a metallic vessel provided with inlet and outlet branches, and is connected with the vessel, so as to be easily disconnected if required. Suitable valves are provided for controlling the admission of steam to the coiled pipes, and of water and vapour, and their exit from the vessel. For details of construction and mode of working, the three sheets of drawings attached to the specification must be consulted.—E. S.

*An Improved Method or Process of and Apparatus for the Lixivation of Various Materials.* H. H. Lake. From "La Société Anonyme des Parfumes Naturels de Cannes," Paris, France. Eng. Pat. 18,528, November 19, 1889. 8d.

This invention relates to improvements in the method and apparatus described in Eng. Pat. 10,280 of 1889 (this Journal, 1890, 325), and is intended to dispense with manual labour, making the apparatus automatic by providing each extractor, either internally or externally according to circumstances, with a float and valve, which have the effect of permitting the passage of the solvent into each extractor either at the entrance or at the discharge, the passage of the gas from one extractor to the other being at the same time stopped automatically.—E. S.

*An Improved Cement used for Covering Boilers, Steam Pipes or Vessels containing Steam or Heated Water.* W. H. Loundsdale, Blackburn. Eng. Pat. 19,906, December 11, 1889. 4d.

The mixture consists of 4 cwt. of ground cork, 1 cwt. of paper pulp, 2 cwt. of charcoal, 3 cwt. of common clay, 3 cwt. of fireclay, 3 cwt. of cowhair or other animal hair or flax, 1 cwt. of soot, 3 cwt. of water, and may be applied as a covering to boilers, &c. in the usual manner.—B. B.

*Improved Process and Apparatus for Cooling Liquids by Means of Air.* J. Klein, Frankenthal, Germany. Eng. Pat. 11,246, July 18, 1890. 11d.

The improved apparatus devised for the above purpose consists mainly of a round or polygonal upright shaft or chamber in which water admitted from the top is brought into intimate contact with a current of air, produced by a fan, moving up in the opposite direction. Inside the shaft a number of plates, preferably of wood, and connected in two or more series, are so arranged that the plates of one series cross those of the other at a suitable angle. The liquid to be cooled is conveyed to the plates, and on reaching them is distributed into thin and even layers, and is brought into contact with the blast moving in the opposite direction. The air thus absorbs a portion of the heat and the liquid reaches the reservoir in a considerably cooled condition. (See also this Journal, 1890, 849.)—E. S.

*Improvements in Evaporating Apparatus.* S. M. Lillie, Philadelphia, U.S.A. Eng. Pat. 11,686, July 25, 1890, By Internat. Conv. December 26, 1889. 8d.

The invention relates to "Intransit Evaporating Apparatus," in which the liquid is evaporated while flowing in comparatively thin films over the heated evaporating surfaces. As regards a single pan or "effect" it consists of a battery of horizontal evaporating tubes, contained in an evaporating chamber, which tubes are closed at one end and at the other are connected with steam supply conduits, from which their interiors are supplied with steam. Above the evaporating tubes in the chamber is a spraying contrivance, fed with the liquid to be evaporated, and by

which it is distributed over the surface of the tubes, and then flows down over the same to the floor of the evaporating chamber. Means are provided to allow the escape of any gases that may collect in the tubes and other parts of the apparatus; and also for the concentrated liquid. For details of the mode of working it will be necessary to consult the drawings attached to the specification. There are 12 claims.—E. S.

*Improvements in Filters and Filtering Apparatus.* R. W. James, London. From E. J. Tobin and T. Davidson, Sydney, New South Wales. Eng. Pat. 13,029, August 19, 1890. 6d.

THE improvements are specially devised to provide increased effective capacity of the filtering medium, while the filter itself may be decreased in size. The invention is equally applicable to domestic and other filtering apparatus.

For a domestic filter a chamber is divided into two parts by a central partition preferably formed of limestone firmly cemented in it, and having an aperture through it allowing of communication between the upper and lower parts containing the unfiltered and filtered liquid. The filtering medium is made by cutting a deep groove or an annulus in the walls of a cylinder, also preferably made of limestone, the ends of the groove being firmly closed. On the foot of the cylinder is fixed a valve with a passage to the groove, and the cylinder is seated upon the partition with the valve entering the communicating aperture, and forming a tight joint. The liquid having filtered through the exterior and interior walls of the cylinder into the groove passes through the passage and valve into the lower part of the chamber, whence it is drawn off by a tap.—E. S.

## II.—FUEL, GAS, AND LIGHT.

*Commercial Condition of Persia.* Board of Trade J. November 1890, 604.

See under X., page 1040.

### PATENTS.

*Improvements in and Connected with the Manufacture of Illuminating Gas from Coal and analogous Material.* J. H. Fergusson, Liverpool. Eng. Pat. 15,947, October 10, 1889. 8d.

THESE improvements are in connection with the arrangements for re-heating or fixing illuminating gas after distillation. The re-heating ducts or fixing retorts are arranged in the upper part of a bench of distilling retorts, but separated therefrom by openings regulated by dampers, &c., for the entrance of the waste heating gases; the ducts may be disposed above the arch of a bench of retorts, and a suitable space formed round them through which the whole or part of the waste gases is made to pass on the way to the flue, the temperature being regulated to 1,000°—1,300° F. The fixing retorts may be single or U-shaped ducts, or they may have an artificially cooled pipe interposed in their course so that the gases are heated, cooled, and re-heated; in any case an artificially cooled pipe is provided on the duct outlet. When such a pipe is interposed between two branches of a fixing retort, tar may be introduced at that point, or it may be introduced at any suitable point of the duct whatever its form. The illuminating gases may be led directly from the retorts through a short valved conduit into the fixing retorts without any condensation of the tarry matters. In this case the gases are heated for a considerable time in passing through a long duct to a temperature not exceeding 1,000°—1,200° F., the junction of the duct with the cooling pipes being shielded from the heat.

Several modifications are described and illustrated by three sheets of drawings.—S. B. A. A.

*Improvements in Apparatus for burning Hydrocarbon or other Oils for Lighting and Heating purposes.* G. Rose, Glasgow. Eng. Pat. 18,101, November 13, 1889. 8d.

THESE improvements are developments of the author's previous patents, Nos. 11,517, 16,497, 17,826, of 1888, and are mainly applicable to that class of apparatus in which steam generated from water supplied to a coil pipe or chamber heated by the flame is used to spray the oil in the burner or combustion box. An oil tank or reservoir has a small water-tank secured to its exterior, interior or bottom, a pipe from the latter tank feeds a small coil pipe enclosed in a metal casing and secured to the upper surface of a broad flange surrounding the nipple of an oil-well burner similar to that described in Eng. Pat. 11,517 of 1888. Oil flows by gravitation through a valve-controlled tube into the oil well of the burner and is there ignited, and as soon as the coil is sufficiently heated steam is forced through a pipe connected with the top of the coil into the steam chamber of the burner, and the oil is forced out through the nipple of the burner in a fine spray. A branch of the steam pipe conveys a portion of the steam to the top of the water tank to produce the pressure necessary for feeding the coil. A valve is described which automatically regulates the water-supply according to the pressure in the tank; the admission of steam to the tank may also be regulated by a valve, and the water-supply pipe may have a syphon bend formed upon it for the purpose of retaining a supply of water in the coil.

A number of modifications and various details are described at length in the specification.—S. B. A. A.

*Improvements in Apparatus for Generating and Burning Gas from Heavy Oils or Carbonaceous Fluids.* W. G. Robinson, Elland. Eng. Pat. 19,121, November 28, 1889. 8d.

THESE improvements relate to the construction of the gas generator and burner of portable and fixed lamps in which hydrocarbon vapours are consumed, and are especially adapted to the apparatus of Eng. Pat. 3696 of 1889. In the improved apparatus, the generator is composed of three or more tiers of tubes, each tier consisting of three short tubes joined in a triangle, and communicating by means of short vertical tubes with the adjacent tiers. For convenience of cleaning, openings secured by screwed stoppers are formed in two of the angles of each tier. The oil is supplied from a reservoir into the lowest tubes of the generator, and the vapours are withdrawn from the uppermost tubes and conveyed to the burner, which is situated directly under the generator, and supplies it with the necessary heat. Pressure may be automatically produced in the reservoir by connecting the vapour exit tube with the upper part of the reservoir. The argand or air-mixing portion of the burner is of a hollow spherical or ovoidal form, with contracted upper and lower orifices, this form preventing undue fluctuation of the light from varying pressure in the reservoir.—S. B. A. A.

*Improved Methods of and Apparatus for Burning Liquid Hydrocarbons.* P. Humbert, Boston, U.S.A. Eng. Pat. 12,843, August 15, 1890. 8d.

LIQUID hydrocarbons, preferably crude petroleum, are converted into a mixture of methane and other gases by treating their vapours with atmospheric oxygen or with the gases from the decomposition of water by heat. The apparatus used consists of a volatilising coil provided with oil and air supply-pipes and with an exit pipe for the vapours connected with a burner placed at some distance below the coil. The coil and burner are enclosed by a cylindrical fireclay or iron shell, and two concentric cylinders successively decreasing in height are placed between the burner and the outer cylinder, and are separated by air passages. Gas issuing from the burner is thus supplied with air at different points, and complete combustion ensues. The coil may be protected from the direct action of the flames

by an internal shell partially closed at the top and provided or not with properly-regulated openings into the coil chamber. For supplying "decomposed water," two chambers or pipes divided into several communicating compartments, and filled with asbestos, are fixed between the volatilising coil and the burner, the water supply is connected with the lower end, and the gases led from the upper end into the volatilising coil.—S. B. A. A.

*Improvements in the Process of and Apparatus for Manufacturing Gas and for the Utilisation of the same.* J. T. Key, London. Eng. Pat. 12,860, August 16, 1890. 8d.

A VERTICAL gas-producer, preferably cylindrical over the middle portion and approximately conical towards the top and bottom, is fitted at the top with a supply hopper of rectangular section, and is fed with fuel by a longitudinally-grooved or recessed drum revolving in the lower end of the hopper. The producer has another rectangular opening at the bottom, bordered internally with side plates, against which the coke, ash or clinker is crushed, before withdrawal by a hollow longitudinally and transversely corrugated perforated drum, which revolves in the lower opening, and has its lower end immersed in water contained in a closed cistern beneath the producer. One wall of the cistern is inclined, and a portion of the water surface exposed, in order to facilitate the removal of the coke, but access of air to the drum is prevented by a curtain wall dipping into the water. The two drums are geared together to ensure corresponding uniformity in the rate of fuel supply, and of the coke discharge, and both drums have hollow axles. Air or steam is admitted into the producer through the hollow axle and perforations of the lower drum.

An improved atmospheric burner, especially suited for steam boilers heated by producer-gas, consists of a short central tube for the hot gas, which widens out and opens into a wider tube surrounding it and attached to it by stays. A core inserted and similarly attached to the other end of the outer tube, reaches almost to the open internal end of the gas passage. Air is supplied into the annular passage, so that the gas and air leave the core end of the burner and enter the flues (of a steam boiler) in concentric currents and not in intimate admixture; the heat of combustion is thus distributed along the whole length of the flues. Perforated firebrick blocks may be placed at intervals within the flues to mix the currents of air and gas more intimately, and to facilitate the absorption of the heat. The details are illustrated by two sheets of drawings.—S. B. A. A.

*Improvements in the Manufacture and Production of Artificial Fuel.* F. Lennard and E. W. Harding, Greenwich. Eng. Pat. 13,033, August 19, 1890. 4d.

SEVEN parts by measure of powdered coal or coal and coke or breeze, two parts of green or spent tan, and one part of coal-tar pitch are thoroughly ground and incorporated in a mechanical mixer, rendered plastic by treatment with superheated steam (340° F.) in a pug mill and compressed in perforated blocks. The proportion of tan may be varied from five parts to one part, and the proportion of pitch from three parts to one-half part. It is alleged that by the addition of tan the ignition of the fuel is sufficiently retarded to ensure perfect combustion.—S. B. A. A.

### III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

*Report on Carbolic Acid and Acids not Specified.*  
Report of the Central Laboratory of the Italian Customs Department, 1886—1889, 302—306.

THE tariff report distinguishes between carbolic acid which contains not more than 20 per cent. of light oil, distilling up to a temperature of 310°, classified as carbolic acid; 2nd, that which contains from 20—30 per cent. of light oil, classified as heavy mineral oil; and 3rd, that which contains above 30 per cent., classified as crude mineral oils (see Report on Oils). For the purpose of analysis, according to these definitions, the direction add to 100 grms. of the sample twice its volume of a 10 per cent. caustic soda solution; the light oil, which separates after some time, is then fractionally distilled.

The report classifies under carbolic acid both the crystallised acid (*Acidum carbolicum crystallisatum*) and the liquid acid (*Acidum carbolicum liquefactum*) under the title of pure carbolic acid.

*Benzoic Acid.*—A distinction is drawn in the tariff between "benzoic acid or flowers of benzoïn," classified as perfumery, and "benzoic acid of every other sort," classified as acids not specified. The compilers remark that such a distinction is only possible when the acid from various sources has not undergone refinement sufficient to make it absolutely pure. It is proposed to distinguish between benzoic acid from gum benzoïn and that obtained from urine, phthalic acid, &c., as follows—1st, a small portion of the sample is sublimed, when the former yields no residue, while the latter gives a small residue of lime; 2nd, when heated with potash, the acid from urine gives off ammonia; and 3rd, in the acid obtained from trichloro-toluene, traces of chlorine can be recognised by the copper oxide test (Jacobsen, *Archiv. der Pharm.* 1884, 366).—V. H. V.

*Report on Bitumen, Pitch, &c.* Report of the Central Laboratory of the Italian Customs Department, 1886—1889, 412—416.

THE tariff mentions "solid mineral tar derived from the distillation of fossil carbon and mineral oils, i.e., black, liquid residues from the same source, and pitchy residues, which do not serve for illuminating purposes or for the extraction of heavy oils." These are defined as "thick pitchy residues of a very deep colour and penetrating odour which remain in the retorts after distillation, and which serve as substitutes for tar and solid bitumen." These are subject to the duty of solid bitumens: liquid pitches, however, which can be worked for the heavy oils, are classed as "liquid mineral tar, derived from the distillation of fossil carbon and mineral oils," and are subject to the duty on heavy oils (q.v.). The harder varieties of pitch used for asphalts and artificial bitumens or for the manufacture of briquettes defined as "combustible agglomerates," are free of duty.

Vegetable tars mentioned in the report under the title of natural gums, resins, &c., are free of duty, while tars prepared for medicinal purposes are classified under the title of compounded medicines.

Residues obtained in the distillations of resins are classed as solid bitumens and subject to a duty of 50 lira per quintal; natural bitumens such as those of Judea, &c., are placed under the same heading, but bituminous earths such as those of Val de Travers are classed as earths, stones, &c. In order then to decide between natural and artificial bitumens the Direction adopted the methods of Durand-Claye (*Annales des ponts et Chaussées*, 1879, 122).

Bituminous schists, "which serve to increase the illuminating power of coal gas" are classed as solid bitumens; in this list boghead coal is included. Natural carbons such as fossil carbon, lignite, and wood carbon which have undergone processes, which would not prevent their employment for purposes other than combustibles, are classified under different headings in the report.—V. H. V.

### IV.—COLOURING MATTERS AND DYES.

*A Method for the Production of Aromatic Sulphides and of Thioxanthone.* T. H. Ziegler. *Ber.* 23, 2469—2472.

RESEARCHES in colouring matters have proved that most of them can be derived from a system of two or more rings.

Antraquinone, xanthone, acridine, phenazine, phenoxazine, and thiodiphenylamine form the foundations of a great many colouring matters distinguished by their fastness and beauty.

The author tried to prepare bodies of the following constitution:—

Beckmann has long ago prepared a derivative of a body constituted according to formula No. 1 by the action of sulphuric anhydride on benzophenone; but thioxanthone could not be obtained from it.

Leuckart and Sandmeyer indicated simultaneously how thiophenols could be prepared. By the action of diazo compounds on these bodies, however, no azo bodies, but sulphides are obtained. Diazobenzene chloride and sodium thiophenolates form, for instance, phenyl-sulphide. The sulphides from diazo-*o*-toluene, diazo-*p*-toluene, diazo- $\beta$ -naphthalene and thiophenol form oils distilling from 290° to 310° C. Phenyl- $\alpha$ -naphthylsulphide crystallises in thin plates, melting at 49° C.

*p*-diazoacetanilide combines with thiophenol and forms *p*-acetamidophenylsulphide melting at 144° C., which, on saponification, yields the amidodiphenylsulphide crystallising from alcohol in needles, melting at 97° C. The preparation of thioxanthone is performed in three steps. By acting with diazoanthranilic acid on sodium thiophenolate diazothiophenyl ether is formed. On treatment with alkalis the sodium salt, diphenylsulphide-*o*-carbonic acid is obtained. The free acid is insoluble in water, but easily soluble in benzene, alcohol, and glacial acid, crystallising from benzene in white plates, melting at 165.5° C. It is soluble in concentrated sulphuric acid with a magnificent light green fluorescence, forming the ketone after a few minutes' heating. On pouring the sulphuric acid solution into an excess of cold water, thioxanthone is precipitated. It is soluble in hot glacial acetic acid, carbon bisulphide, and benzene, and crystallises in yellow needles, melting at 203°—205° C. On distillation or sublimation and crystallisation from benzene, white crystals are obtained, melting at 207° C., and boiling from 371°—373° C. under a barometric pressure of 7.5 mm.—A. L.

*The Action of Sulphur on Organic Compounds and the Synthesis of Tetraphenylthiophen.* T. H. Ziegler. *Ber.* 23, 2472—2476.

THE action of sulphur on diphenylmethane originated the idea of examining benzene derivatives containing a methyl or methylene group. Two mols. of phenylacetic acid were heated with one mol. of sulphur. At 220° C. evolution of sulphuretted hydrogen begins, which ceases after six hours, the temperature having gradually risen to 260° C. The product of the reaction is a thick fluid, easily soluble in benzene and carbon bisulphide, though little in alcohol. After purification, white microscopic needles were obtained, melting at 181°—182° C. They are tetraphenylthiophen. The same body can also be prepared by the action of

sulphur on dehydroxybenzoïn. It is very stable towards chemical agents; on treatment with concentrated nitric acid, however, a tetranitro-compound is formed. The stability of the hydrogen atoms in the benzene ring towards sulphur is very remarkable. Mixtures of benzophenone and azobenzene with sulphur are not acted upon even on boiling them. Triphenylmethane behaves in a like manner, no sulphuretted hydrogen being evolved, even on heating it with sulphur to 300° C. In other cases it is easily movable, as the formation of the *o*-hydroxythiophenols, of thiodiphenylamine, and of other bodies proves. In all these reactions the replacement of the benzene hydrogen is due, according to the author's views, to the presence of a basic group. Of special interest is the action of sulphur on toluidine, and experiments prove that Plüztzinger and Gattermann's views of the constitution of dehydrothiitoluidine and of the primuline base are correct.—A. L.

*On Meso-anthramine.* F. Goldmann, Ber. **23**, 2522—2526.

Of the monohydroxy derivatives of anthracene two are known: Anthrol—

and Anthranol—

Of the corresponding amines only anthramine—

has been described. The author has prepared its isomeride, which he calls *Meso-anthramine*—

by heating finely-powdered anthranol with 20 times its weight of a concentrated aqueous solution of ammonia containing 25 per cent. of ammonia for 12 hours at 200° C. The product of the reaction consisted of yellow crystals and a yellow solution. The crystals were dried on porous plates and dissolved in alcohol. An alcoholic solution of hydrochloric acid was added and the hydrochloride of the new base precipitated. Ammonia precipitates the free base, which is purified by solution in cold alcohol and precipitation with water. It forms golden plates, decomposing at 115° C. It is very unstable and darkens even in the desiccator, is insoluble in water, soluble in alcohol, ether, chloroform, and benzene, with a yellow colour and green fluorescence. On oxidising it with a solution of chromic acid in glacial acetic acid *anthraquinone* is produced. Diazobenzenesulphonic acid produces with the alcoholic solution of meso-anthramine-hydrochloride a beautiful magenta colouration, from which a red colouring matter, probably an azo dyestuff, separates. It is insoluble in alcohol and water, but dissolves in dilute ammonia.

*Acetylmeso-anthramine.*  $\text{C}_{14}\text{H}_{13}.\text{NH}.\text{C}_2\text{H}_3\text{O}$ , obtained by the action of cold acetic anhydride on the base, forms colourless needles melting at 273°—274° C.

*Diacetylmeso-anthramine.*  $\text{C}_{14}\text{H}_9\text{N}(\text{C}_2\text{H}_3\text{O})_2$ , was obtained by boiling the monoacetyl compound for two hours with acetic anhydride. It forms colourless plates melting at 159° C.

*Meso-anthraminehydride.*  $\text{C}_{14}\text{H}_{11}\text{NH}_2$ , was prepared by boiling an alcoholic solution of meso-anthramine with sodium amalgam and precipitating the solution, after the reaction is finished, with water. The new base forms colourless needles melting at 92° C. and soluble in alcohol, benzene and ether. It forms salts with acids. On boiling the aqueous solution of the hydrochloride of the hydrated base it decomposes and forms anthracene and ammonium chloride,  $\text{C}_{14}\text{H}_{11}\text{NH}_2\text{HCl} = \text{C}_{14}\text{H}_{10} + \text{NH}_4\text{Cl}$ .—A. L.

*Benzylloxanthranol.* C. Bach. Ber. **23**, 2527—2530.

*Benzylloxanthranol chloride*—

obtained by the action of phosphorus pentachloride on dry benzylloxanthrol forms colourless plates melting from 95°—102° C.

*Benzylidihydroanthranol*—

was obtained from benzylloxanthranol by reduction with zinc dust and ammonia. It forms yellowish needles decomposing at 130—140° C. On boiling it with acetic acid it decomposes into benzylanthracene and water—

*Benzylanthranol*—

was prepared by treating bromobenzylene anthrone, dissolved in alcohol, with the calculated amount of sodium amalgam. Yellow needles melting at 183—184° C., soluble in alcohol, ether and glacial acetic acid were obtained.

*Ethylhydroxybenzylene anthrone*—

is formed when bromobenzylene anthrone is treated with sodium ethylate. It forms yellow plates melting and decomposing at 173°—175° C., soluble in ether, alcohol, benzene and glacial acetic acid.

*Amidobenzylene anthrone*—

is obtained by treating a solution of bromobenzyleneanthrone in benzene with dry ammonia. It is an orange amorphous body, melting at 150—152° C.

*Benzylanthracenedihydride*—

is the final product of the reduction of benzylanthracene. It crystallises in prismatic needles, soluble in alcohol, and melts at 110—111° C.—A. L.

*On Triphenylamine Derivatives.* R. Herz. Ber. **23**, 2536—2542.

*Nitrotriphenylamine* is prepared by treating a solution of triphenylamine in glacial acetic acid with a mixture of nitric and glacial acetic acid (3 : 5), finally heating to 45—50°. It crystallises from acetic acid in golden yellow needles

melting at  $139^{\circ}$ – $140^{\circ}$ , and dissolves readily in the usual solvents. With concentrated sulphuric acid a deep blue colour is produced. By reduction with tin and hydrochloric acid, the tin double salt of *Amidotriphenylamine* may be prepared. The free base readily oxidises in the air, being coloured a reddish-violet. The acetyl derivative is also described.

*Dinitrotriphenylamine* is obtained in a similar manner to the mono-nitro derivative by treating with a somewhat stronger mixture (equal parts) of glacial acetic and nitric acid and afterwards heating to  $55^{\circ}$ – $60^{\circ}$ . After recrystallising from acetic acid, fine yellow needles melting at  $206^{\circ}$ – $207^{\circ}$  are obtained. Concentrated sulphuric acid colours it violet-blue. By reduction with tin and hydrochloric acid *Diamidotriphenylamine* is readily prepared. After recrystallising from very dilute alcohol pointed needles separate which melt at  $187^{\circ}$ , being decomposed at the same time. The diacetyl derivative is prepared in the usual manner.

*Trinitrotriphenylamine* is prepared in the same way as the dinitro derivative, the temperature being finally raised to  $100^{\circ}$ . It separates at once in bronzy yellow needles and the yield is quantitative. The melting point after boiling in glacial acetic acid, in which the compound is almost insoluble, rises to  $280^{\circ}$ . Heydrich some years ago states that by oxidising a glacial acetic acid solution of the hydrochloride of triamidotriphenylamine with chloranil, he obtained a safranine reaction. The author could not arrive at the same result, always obtaining instead deep blue to violet induline-like colourations. However, on dissolving 0.0005 grm. of the base in 5 cc. concentrated sulphuric acid, containing a trace of fuming nitric acid, a deep green solution resulted, changing to dark blue on warming. On now adding water drop by drop to the cooled solution, the latter gradually assumed a brilliant red fluorescence which soon changed to violet and then magenta-red.

By the action of diphenylamine on pieryl chloride in toluene solution *Diphenylaminapieryl chloride* may be prepared. It crystallises from dilute alcohol in ruby-red needles melting at  $65^{\circ}$ – $66^{\circ}$ .

*Sodium triphenylaminetrisulphonate*.—Triphenylamine is gradually introduced into an excess of fuming sulphuric acid at  $60^{\circ}$ . The sodium salt is with difficulty soluble in dilute alcohol.

*Diphenylnaphthylamine* is prepared by adding 3.5 grms. of potassium to a boiling solution of 20 grms. of diphenylamine and 15 cc. of aniline. 20 grms. of  $\alpha$ -bromonaphthalene are now gradually introduced, and after boiling for a quarter of an hour the mixture is fractionated. When all aniline has distilled over, the pressure is reduced to about 80 mm. At  $230^{\circ}$ – $260^{\circ}$  some unchanged diphenylamine first distils over. The portion distilling at  $335^{\circ}$ – $340^{\circ}$  is dissolved in boiling acetone precipitated with alcohol and recrystallised from dilute alcohol, when silky needles are obtained, melting at  $142^{\circ}$ . Diphenylnaphthylamine dissolves in concentrated sulphuric acid with a green colour and on warming, in contradistinction to triphenylamine, a sulphonic acid is at once formed.—A. R.

*The Constitution of Dinitro- $\beta$ -Naphthol.* E. Loewe.  
Ber. 23, 2542–2546.

By oxidation of dinitro- $\beta$ -naphthol Graebe and Drews obtained  $\beta$ -nitrophthalic acid (1:2:4), which proves that in nitrating  $\beta$ -naphthol, one nitro-group enters into each nucleus of the latter. Moreover, the nitro-group which is contained in the non-hydroxylated nucleus must occupy the  $\beta$ -position, but which  $\beta$ -position is uncertain, and it has not been shown in what position the other nitro-group is in.

This research was undertaken with a view of ascertaining these facts. *Diamido- $\beta$ -naphthol* was first prepared by reduction with tin and hydrochloric acid, and after distilling the base, the hydrochloride was obtained in almost colourless needles by addition of concentrated hydrochloric acid. The base itself oxidises very readily in the air. The triacetyl and tribenzyl derivatives of this compound are also described. *Diamido- $\beta$ -naphthylamine* may be prepared by reducing the corresponding nitro derivative described by Graebe and

Drews. The latter was first obtained in a very pure state by extracting with xylene; it was then reduced with tin and hydrochloric acid, and the base after distillation converted into the hydrochloride with concentrated acid. For determining the position of the nitro-group in the hydroxylated nucleus of dinitro- $\beta$ -naphthol the author tried whether a condensation between diamido- $\beta$ -naphthylamine and phenanthrenequinone could be effected. A eurhodine was indeed obtained, soluble in hydrochloric acid with a reddish-brown colour, and in concentrated sulphuric acid with a violet colour, which turns brown on diluting with water. It sublimes readily and its ethereal solutions show a brilliant fluorescence. The formation of the body is a proof that in dinitro- $\beta$ -naphthol one nitro-group is in the ortho position to the hydroxyl group. A solution of the question which of the two  $\beta$ -positions in the non-hydroxylated nucleus is occupied by the other nitro-group had to be abandoned for the present, owing to the very small yields of diamidonaphthalene obtained from the above-mentioned dinitro- $\beta$ -naphthylamine by diazotising and reducing. The former base the author proposes to convert into a dichloronaphthalene by Sandmeyer's method, whence conclusions may eventually be drawn as to the position of the two nitro-groups in dinitro- $\beta$ -naphthylamine, and consequently also in dinitro- $\beta$ -naphthol.—A. R.

*Oxidation Products of Orthodiamines and Ortho-amidophenols.* O. Fischer and E. Hepp. Ber. 23, 2787–2789.

KERMAN (this Journal, 1890, 934) believes  $\alpha$ -amido- $\alpha$ -naphthylazine to be—

whilst the authors consider it as a true amido compound—

Experiments have proved that it can be diazotised and that on treatment with hydrochloric acid a phenol is formed. Furthermore, eurhodines have been prepared from  $\alpha$ -phenylenediamine and benzene-azo-ethyl-naphthylamine and benzylazodimethylnaphthylamine. The formation of the eurhodine—

proves that amidonaphthophenazine really does contain an amido group.

The reaction of  $\alpha$ -phenylenediamine on amines proceeds in different ways according to the nature of the amines. Amido-azo-naphthalenes take part in the reaction, whilst amido-azo-benzenes act mostly as dehydrogenating agents.  $\alpha$ -phenylenediamine and amido-azo-benzene hydrochloride form principally diamidophenazine whilst  $\alpha$ -amidophenol and amido-azo-benzene hydrochloride form triphenioxazine.

—A. L.

*Fluorindines.* O. Fischer and E. Hepp. Ber. 23, 2789–2793.

FLUORINDINES are produced by the action of heat on azophenines, by the action of  $\alpha$ -phenylenediamine hydrochloride on its red oxidation product. They are further contained in nearly all induline melts.

*Fluorindine from Azophenine* is formed by continuous treatment of azophenine. A violet colouring matter is formed as intermediate product. It is also obtained by

heating azophenine with 2—3 parts of zinc dust. It can be easily isolated, as it is nearly insoluble in alcohol, ether, benzene, toluene, and chloroform, but it imparts to alcohol a beautiful fluorescence. The red-violet solution appears in reflected light as fiery red, whilst addition of hydrochloric acid produces a greenish-blue solution with a brownish-red fluorescence. Fluorindine is a very stable body, resisting the action of concentrated hydrochloric acid even at 250° C. Its melting point could not be determined as it partly sublimes, a bluish-violet vapour being evolved. Analysis gave the formula  $C_{30}H_{20}N_4$ , and its constitution is probably explained in the following equation—

It is a weak base and therefore a weak colouring matter. The intermediate violet product is probably an induline,  $C_{30}H_{23}N_4$ , of the constitution—

*Fluorindine from Diamidophenazine.*—The red oxidation product of *o*-phenylenediamine is diamidophenazine. If four parts of its hydrochloride are heated with three parts of *o*-phenylenediamine in an oil-bath for 10–15 minutes to 200°–210° C., a black powder is obtained, which is treated with boiling dilute sulphuric acid. The green sulphate of the new fluorindine remains as a greenish powder, which yields on boiling with alcoholic ammonia the free base as a brownish-violet powder, insoluble in nearly all solvents. By treating it for days together in an extraction apparatus with benzene-alcohol, plates are obtained of a greenish lustre, imparting to alcohol a beautiful yellowish-red fluorescence. Its formula is  $C_{18}H_{12}N_4$ , and its constitution is explained by the equation—

The authors call the new body *Homofluorindine*.—A. L.

*The Action of Quinones on o-Diamines and o-Nitro-aniline and Nitroparatoluidine.* J. Leicester. Ber. **23**, 2793—2798.

ANILINE acts on quinone, forming quinone-anilide. Ortho-diamines ought therefore to produce bodies of the type—

or of the type—

Perhaps the reaction might go further, and quinonephenazine

or quinonefluorindine—

might be produced. On carrying out these experiments a mixture of substances was obtained, the purification and separation of which were very difficult. The experiments were therefore simplified by using orthonitro-amido compounds instead of *o*-diamido bases.

*Quinone-o-dinitro-anilide* was obtained by boiling 3 parts of quinone with 2.5 parts of *o*-nitro-aniline in a solution of glacial acetic acid for two hours. On cooling, red crystals separate from the solution, which after crystallisation from alcohol form red needles melting and decomposing at 305° C. They consist of

On reducing this compound with alcoholic ammonium sulphide at 100° C., colourless crystals are obtained, which, however, turn blue-black in the air. They were recrystallised from a mixture of methyl-alcohol and benzene, and form dark green crystals looking exactly like homofluorindine. They have the same blue colour and fluorescence in a solution of glacial acetic acid; they are, however, not identical with homofluorindine, but contain oxygen. The formula of the new body is—

*Quinone-*o*-nitrotoluide*—

forms red crystals decomposing at about 300° C.

*Quinone-o-dinitrotoluide—*

forms bronze-coloured plates decomposing at 140° C

*Quinone- $\alpha$ -methylphenazine—*

was obtained from the monitrotoluidoquinone by reduction with alcoholic ammonium sulphide at  $100^{\circ}\text{C}$ . It forms bronze-coloured crystalline powder, soluble in alcohol with a violet colour; its solution in glacial acetic acid is greenish blue, and shows a weak red fluorescence.

*Toluquinone- $\alpha$ -nitroanilide—*

obtained from toluquinone and  $\alpha$ -nitroaniline, forms red crystals decomposing at  $230^{\circ}\text{C}$ . On reduction it yields

*Quinonephenotolazine—*

crystallising in red leaves.

The author prepared further—

*Toluquinonenitrotoluide—**Quinonetolazine—*

dark red leaves, soluble in alcohol and in glacial acetic acid.

 *$\alpha$ -Naphthoquinone- $\alpha$ -nitroanilide—*

yellow crystals.

 *$\alpha$ -Naphthoquinonephenazine—*

green plates from alcohol.

 *$\alpha$ -Naphthoquinonenitrotoluide—*

orange needles.

 *$\alpha$ -Naphthoquinonetolazine—*

steel blue plates with a greenish lustre.—A. L.

*On the Constitution of the so-called Carbazines.* M. Freund and F. Kuh. Ber. **23**, 2821—2844.

FURTHER researches on the action of phosgene gas on the acid derivatives of phenylhydrazine have disclosed the fact that the compounds originally described as derivatives of a hypothetical compound, carbazine—

must be regarded from a totally different point of view. It appears that the derivatives of phenylhydrazine are capable of reacting in two distinct ways, either in accordance with the usual formula,  $\text{C}_6\text{H}_5\text{—NH—NHCO}R$  or its tautomeric one,  $\text{C}_6\text{H}_5\text{NH—N}=\text{C(OH)R}$ . In the case of the action of phosgene gas the latter formula is considered the most likely by the authors, and to the hypothetical basis of the compounds produced they assign the formula—

Hantzsch having introduced the term “azole” for nuclei in which one  $\text{CH}_2$  group is replaced by a diad, the authors propose to call the last-mentioned compound “biazole,” whereas the two substances represented by the formulae—

are called respectively biazoline and biazolone. The reasons for coming to the above conclusions regarding the constitution of the compounds hitherto known as carbazines are:—

1. Only one molecule of phosgene gas reacts with diphenylcarbazine, the older view requiring two.
2. The behaviour of the acetyl derivatives towards phosphorus pentachloride prove the presence of only one, not two, movable oxygen atoms.
3. Certain of these bodies do not react with carbon oxysulphide which is not in accordance with the older views on the constitution of these substances. For the details of this research, which are unsuited for abstracting, the original article must be consulted.—A. R.

*Tetramethylbenzidine and its Dye-stuff Derivatives.* II. von Perger and F. Ulzer. Mittheil. des k. k. Tech. Gew.-Museums, 1890, 34—43.

THE authors tried to prepare tetramethylbenzidine by Michler and Pattinson's method, which consists in heating together under pressure benzidine, methyl iodide, and methyl alcohol, and decomposing with soda-lime the resultant methyl ammonium iodide. They found the yield, however, exceedingly small and the method consequently of no technical value. A better mode of preparation is based on a reaction observed by Michler and others (Ber. **12**, 1171, and **17**, 115), namely, the production of tetramethylbenzidine by heating dimethylaniline with sulphuric acid. In employing this reaction, the authors obtained the best results by the use of fuming sulphuric acid containing a small percentage of sulphuric anhydride. A 30 per cent.

yield of base was obtained when 25 parts of dimethylaniline were heated for eight hours at  $210^{\circ}$  with 85 parts of acid containing 4 per cent. of anhydride. In another experiment, using a larger proportion of acid, a 40 per cent. yield resulted, and, in this instance, 20 per cent. of unchanged dimethylaniline was recovered, so that technically a 50 per cent. yield may be said to be obtained. The base was separated from the acid mixture by pouring the latter into water, neutralising, removing the unchanged dimethylaniline by a current of steam, precipitating the tetramethylbenzidine as hydrochloride, clarifying a solution of this salt with animal charcoal, decomposing with ammonia, and purifying the free base by a single recrystallisation from alcohol, which renders the base pure enough for experimental purposes.

The dinitro-derivative (melting point  $188^{\circ}$ ) was prepared by adding the calculated amount of sodium nitrite to a hydrochloric acid solution of the base and crystallising from alcohol. Michler and Pattinson state that an orange-coloured compound is thus formed. The authors, however, find that a green nitroso-compound, melting at  $140^{\circ}$ , is first formed, and that this on exposure to the air is oxidised to the orange nitro-derivative. An isomeric dinitro-compound (melting point about  $167^{\circ}$ ) is found accompanying the last-mentioned compound. This the authors intend to further examine. Endeavours to effect the nitration with gaseous nitrous acid, as in the case of nitro-alizarin, and with nitric acid, were unsuccessful, it being found impossible to control the reaction.

Diamidotetramethylbenzidine was obtained by reducing the dinitro-compound above mentioned (melting point  $188^{\circ}$ ) with tin and hydrochloric acid, and was separated with ammonia, after the tin had been precipitated with hydrogen sulphide. Recrystallised from alcohol it closely resembles in appearance tetramethylbenzidine, and melts, as observed by Michler and Pattinson, at  $168^{\circ}$ . The yield is almost the theoretical. From the diamido-base so obtained, a range of tetrazo-dyes was prepared by diazotising and combining the tetrazotetramethyldiamidodiphenyl solution formed, with the following naphthol- and naphthylamine-sulphonic acids, the results being tabulated below:—

	Colour yielded by Dyestuff on Silk or Unmordanted Cotton.
1. Naphthionic acid ( $\text{NH}_2:\text{SO}_3\text{H} = 1:1$ ).....	Brown-yellow.
2. Naphthylamine sulphonic acid— ( $\text{NH}_2:\text{SO}_3\text{H} = 1:5$ ).....	Brown-yellow.
3. $\beta$ -naphthylamine sulphonic acid— ( $\text{NH}_2:\text{SO}_3\text{H} = 2:6$ ?—Brönmér's).....	Brown-yellow.
4. $\beta$ -naphthylamine- $\delta$ -sulphonic acid.....	Red.
5. $\beta$ -naphthylamine- $R$ -disulphonic acid.....	Pale brown-red.
6. $\beta$ -naphthol- $\beta$ -sulphonic acid— ( $\text{OH}:\text{SO}_3\text{H} = 2:6$ ).....	Chocolate-red.
7. $\beta$ -naphthol- $\alpha$ -sulphonic acid (Bayer's croceic acid).....	Dyeing power very feeble.
8. $\beta$ -naphthol- $R$ -disulphonic acid.....	..
9. $\beta$ -naphthol- $G$ -disulphonic acid.....	..

In view of the small yields of some of the intermediate products and consequent expensive nature of the diamido base, the dyes formed, to be technically available, would require to be of unusual intrinsic value, which it is evident they are not. It remains to be seen whether an isomeric diamidotetramethylbenzidine will yield more valuable dyes.

—E. B.

*On the Formation of Anthraquinone under peculiar Conditions.* L. H. Friedberg. J. Amer. Chem. Soc. **12**, 26—43.

LACBENZHEIMER'S phenanthrene-quinone reaction (Ber. **8**, 224) has been shown by Victor Meyer to be due to  $\alpha$ -methylthiophen,  $\text{C}_6\text{H}_4\cdot\text{S}\cdot\text{CH}_3$ , which is contained in all commercial toluenes. The reaction is carried out as follows:—A few drops of the toluene are added to a dilute solution of phenanthrene-quinone in glacial acetic acid. The mixture is cooled continually, and drops of concentrated sulphuric acid are allowed to run into it. After a few minutes water is added, when a colouring substance is precipitated, which on shaking with ether dissolves with a beautiful blue tint. This colouring matter appears to have the formula  $\text{C}_{19}\text{H}_{12}\text{OS}$ . (V. Meyer, "Die Thiophengruppe," 40), being formed according to the equation—

It is a dark blue powder, which on pressure assumes a copper lustre. It is easily soluble in alcohol, benzene, chloroform, and carbon bisulphide, but is insoluble in water. When heated alone it does not undergo any change, but in presence of lead chromate, anthraquinone is formed. This pyrogenetic change is remarkable, and since the green colouring matter obtained by the action of phenanthrene-quinone upon thiophen does not yield it under analogous conditions, it appears likely that the methyl group of the thiophen has to do with the formation of the anthraquinone.

The author enters into a detailed theoretical explanation of the manner in which the anthraquinone might be formed, in which he assumes the intermediate formation of thiophen aldehyde from the blue colouring matter, which then loses  $\text{CO}_2$ ,  $\text{H}_2\text{S}$ , and  $\text{COS}$ , and undergoes certain molecular rearrangements to form anthraquinone. The suppositions are not supported by any experimental data, but the author intends to test their correctness by crucial experiments.

—C. A. K.

*Report on Colours.* Report of the Central Laboratory of the Italian Customs Department, 1886–1889, 371–378.

**I. Coal Tar Colours**, distinguished as "colours derived from coal-tar in the dry state, in paste or as liquids," are free of duty. Among extraneous substances added were found dextrin, sugar, magnesium and sodium sulphates, and sodium chloride, often to such a degree as to modify the tariff regulation; thus samples, declared as coal-tar colour, consisted principally of an aqueous solution of sugar, coloured with a trace of colouring matter; these were classed as syrups, earminic acid (q.v.). Solutions of caramel and coal-tar colours were classed with "confectionery and preserves with sugar and honey."

**Coloured Extracts from Dye-Woods** pay 12 lire per quintal. Samples were sent of vegetable colours to which coal-tar colours had been added either for the purpose of fraud or of beauty; these were classed under the former category and liable to duty. Samples were also sent of extract of logwood sophisticated with extract of chestnut; for their examination the method proposed by Houzeau (Compt. Rend. **68**, 716) was adopted.

**Colours in Cakes, Powder, and of every other kind** pay 12.50 lire per quintal; among exceptions are included certain coloured earths, ochres, natural and artificial, classed as "coloured earths," also certain metallic oxides such as ferric oxide, minium, &c., and certain metallic compounds, mercury sulphide, lead carbonate, &c., specially classed. Coloured lacquers are classed as colours in cakes.

Samples declared as a solid coal-tar colour were recognised as a mixture of barium and calcium sulphates, coloured with a coal-tar colour; another declared as chemical products not specified, was a mixture of lead chromate (lead vermillion) and barium sulphate, while a sample of lead chromate (chrome yellow) was declared as a coal-tar colour.

—V. H. V.

## PATENTS.

*Manufacture of Indulin-like Colouring Matters.* O. Imray, London. From "The Farbwerke Griesheim-am-Main, W. Noetzel and Co.," Germany. Eng. Pat. 17,204, October 30, 1889. 4d.

A process for obtaining reddish-violet, reddish-blue, and grey-black colouring matters by reacting on primary aromatic amines with the hydrochlorides of nitrosodimethylaniline or nitrosodiethylamine together with hydrochloric acid and at temperatures between 90° and 150° C. 30 parts of aniline are heated to 90° together with 15 parts of hydrochloric acid of 20° B. and 25 parts of nitrosodimethylaniline are gradually added. A violent reaction occurs, after which the melt is raised to 120° when it becomes thick and solidifies on cooling. To purify it, it is powdered and dissolved in dilute hydrochloric acid, from which solution the dyestuff is precipitated with salt.—T. A. L.

*Process for the Preparation of Orange-Yellow Colouring Matters.* O. Imray, London. From "The Actien Gesellschaft für Anilin Fabrikation," Berlin, Germany. Eng. Pat. 17,957, November 11, 1889. 4d.

AN extension of Eng. Pat. 15,296 of 1885 (this Journal, 1886, 595, and 1889, 701) and of Eng. Pat. 2213 of 1886 (this Journal, 1887, 138, and 1889, 701). The dyestuffs referred to in the previous patents are obtained by the action of diazotised benzidine or toluidine on  $\beta$ -naphthylamine disulphonic acid R and phenol. Owing to the presence of the free hydroxyl group in the dyestuff it is sensitive to alkalis, but this can be prevented, as described in the present patent, by methylating or ethylating the hydroxyl group by heating the colouring matter with ethyl bromide or methyl iodide in dilute alcohol and in presence of caustic soda. The reaction takes place when the mixture is boiled under an inverted condenser and when completed the alcohol is distilled off and the dyestuff precipitated with salt.—T. A. L.

*Improvements in the Manufacture and Production of Direct-Dyeing Yellow Colouring Matters.* B. Willeox, London. From "The Farbenfabriken vormals F. Bayer and Co." Elberfeld, Germany. Eng. Pat. 18,354, November 16, 1889. 6d.

THE dehydrothiotoluidine melting at 191° C. (obtained by the action of sulphur on *p*-toluidine) or its sulphonic acid when diazotised can be combined with another molecule of dehydrothiotoluidine or with dehydrothiotoluidine sulphonic acid in an acetic acid solution. The mixture is allowed to stand several days at 20°–30° C., and is then raised to 60°–80°, and kept at this temperature until a sample dissolves to a clear solution in soda. The whole is then boiled, neutralised with soda, and the colouring matter separated in the usual way. The so-called prinnuline base or its sulphonic acids, and the bodies obtained by the action of sulphur on *m*-xylydine or  $\psi$ -cumidine may also be employed in a similar manner. The products dye unmordanted cotton greenish yellow. (See also this Journal, 1890, 854.) —T. A. L.

*Improvements in the Manufacture or Production of Azo Colouring Matters.* B. Willeox, London. From "The Farbenfabriken vormals F. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 18,517, November 19, 1889. 4d.

AN extension of Eng. Pat. 13,665 of 1889 (this Journal, 1890, 854). The dihydroxynaphthalene monosulphonic acid there described, when combined with diazo compounds preferably in an acetic acid solution, gives colouring matters of a bluer shade than those obtained from the naphthol sulphonic or carboxylic acids.—T. A. L.

*Improvements in and Connected with the Manufacture and Production of Direct-Dyeing Colouring Matters for Dyeing and Printing.* B. Willeox, London. From "The Farbenfabriken vormals F. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 18,519, November 19, 1889. 6d.

THESE dyestuffs are produced by first combining one molecule of tetrazodiphenyl chloride or tetrazoditolyl chloride with one molecule of *o*- or *m*-cresol carboxylic acid by which means an intermediate compound is produced. This then combines with another molecule of a phenol or amine producing new colouring matters. 20 kilos. of benzidine sulphate are converted into tetrazodiphenyl chloride and run into 11 kilos. of *m*-cresol carboxylic acid dissolved in weak acetic acid. The solution is then made slightly alkaline with soda and after standing some time is added to an acetic acid solution of 25 kilos. of  $\beta$ -naphthylamine disulphonic acid R. After about 12 hours the mixture is heated to 80° C., and made alkaline with soda lye. The colouring matter thus obtained is salted out and separated in the usual way. Various other amines and phenols may be employed in place of the  $\beta$ -naphthylamine disulphonic acid mentioned.—T. A. L.

*Process for the Manufacture of Picric Acid from Crude Phenols.* W. P. Thompson, Liverpool. From E. de Lom de Berg, Brussels, Belgium. Eng. Pat. 18,904, November 25, 1889. 6d.

CRUDE phenol is treated with sulphuric acid, in proportion to the amount of crystallisable phenol contained, the sulphonic acid dissolved in water and then nitrated. The cresol is said to be unaffected by this treatment. When the reaction is completed the whole is concentrated to the consistency of a syrup and treated with sulphuric acid so as to convert any remaining cresol into its sulphonic acid, thus rendering this body very soluble. The picric acid remaining after the product of the reaction has been taken up with water is purified by recrystallisation. Another process is to conduct the nitration, after sulphonating as above, so that liquid nitrocresol results, which can then be converted into tri-nitrocresol, whilst the decanted liquor is further treated with nitric acid to form pure picric acid.—C. A. K.

ERRATUM.—In this Journal, 1890, 933, for "Cyanamides" throughout the abstract read "Cyanamines."

## V.—TEXTILES: COTTON, WOOL, SILK, Etc.

*A New Fibre in Lagos.* Board of Trade J. November 1890, 596.

THE Lagos Weekly Times for the 30th August publishes a minute by Sir Alfred Moloney, Governor of Lagos colony, on the bass fibre of the bamboo palm (*Raphia vinifera*) known in Yoruba as the *Igi Oguro*. This production promises to become an important and valuable addition to the exports from Lagos. The following information is extracted from the memorandum in question:—

The "African bass" is one of the commonest native fibres of this colony—used by every fisherman in the manufacture of his lines, and prepared from one of the most plentiful of the palm trees of the colony, the *Raphia vinifera*, or "bamboo" palm.

The "African bass" is in appearance a stiff and wiry fibre, varying in colour from dark brown to light red, dependent for its shades on duration of soaking. It is most readily obtained in lengths of from 3 ft. to 4 ft., beyond which length it is inconvenient to pack, and difficult to procure without injury to the tree. In diameter it varies from  $\frac{1}{16}$ th to  $\frac{1}{32}$ th of an inch, the latter of which may be

accepted as the limit of fineness to be admitted in a commercial sample for the European market. It is said to be used mainly in the manufacture of hard brushes for various domestic and manufacturing purposes. The demand appears to be very large, and the price is exceedingly satisfactory. The source of its supply in this colony alone may be said to be practically inexhaustible.

### PATENTS.

*Improvements in the Treatment of Vegetable Fibrous Material to obtain Fibre therefrom, and in Apparatus therefor.* G. W. Robertson, Glasgow; D. Black, Lenzie; and J. McGlashan, Edinburgh. Eng. Pat. 12,626, August 10, 1889. 8d.

THE bark (raw or green bark as well as "ribbons") of the fibre yielding *Urticaceæ*, viz., rhea, ramie, china grass, &c., is first soaked in cold or hot water, or in a weak solution of caustic soda or other alkali for 6–12 hours, until thoroughly softened. It is then passed through a machine, having heavy iron rollers, in order to break the outer skin, to remove impurities and the liquid, and to straighten the fibres. One roller travels faster than the other, whereby a slight draft on the fibres is produced. Then the material is wound in ribbons on bobbins or reels with hollow and perforated centres, each ribbon being laid between webs of wire, so that the liquids may have free access to every part of the material. A number of these bobbins is mounted on vertical spindles inside a keir or boiler, containing a solution of caustic soda or other alkali from 2°–4° Tw. strength, and boiled under steam pressure for an average of 12 hours, the bobbins being suitably rotated on their spindles. Then the alkaline liquid is run off and may be used in a dilute state for the preparatory bath mentioned above. After that the material is carefully washed with hot or cold water. Next the bobbins are unwound, the fibres passed through rollers, dried, conducted through a series of heckling machines, and then carded, combed, or otherwise treated preparatory to spinning.—H. S.

*Improved Apparatus for and Method of Extracting Oleaginous and other added Matters from Fibrous, Spun, Textile, and other analogous Substances.* E. Mansfield, London. Eng. Pat. 14,364, September 12, 1889. 8d.

AN arrangement of apparatus for subjecting dirty cotton waste or similar material to alternate squeezing and expansion whilst under the action of an alkaline liquid, for the purpose of removing grease and dirt.—K. E. M.

*Improvements in or Connected with the Manufacture of Carpets, Matting, Twine, and the like from Esparto Grass.* J. E. Richardson, Carlisle. Eng. Pat. 15,135, September 25, 1889. 4d.

ESPARTO grass is put into a tank and water added for maceration. Caustic soda or potash may be added, about 5 to 15 pounds to each ton of the material, to facilitate the maceration; in some special cases dilute mineral acids, added in the same proportions, serve the same purpose. The time of maceration varies considerably, viz., from 7 to 30 days, when water only is used, and from 3 to 14 days if the above chemicals are employed. When the maceration is complete, the chemicals and impurities have to be removed by thoroughly washing with water for a further period of one or several weeks. Then the grass is taken out and passed through rollers, care being taken that it does not become too dry. After this it is subjected to the action of wooden beaters which process partly disintegrates the fibre; it is then passed through grooved steel or iron rollers, and lastly through smooth rollers which complete the disintegration, then it is carded and spun into rope, twine, or yarn. The goods, when made, are passed through hot rollers to finish them.—H. S.

*Improvements in the Treatment of Textiles by Means of Ammoniac Copper for the Purpose of making them Waterproof and Uninflammable.* C. Baswitz, Berlin, Germany. Eng. Pat. 16,708, October 22, 1889. 6d.

See under XIH., page 1047.

*Improved Means and Apparatus for Ungumming and otherwise Treating Flax and other like Fibres, also Leaves and Plants.* E. Johnson, London. From T. Burrows, Lille, France. Eng. Pat. 17,137, October 29, 1889. 11d.

THE loose materials are placed in cages which are fitted in an air- and steam-tight shell or boiler, these cages having either a rotary or an up-and-down motion. The shell is half filled with water or other suitable liquid, and then steam is admitted, to obtain pressure at the upper part of the shell. By the alternate action of the liquid and of the steam, a complete ungumming or retting is effected in a short time, without injury to the fibres.—H. S.

*A New or Improved "Proofed" Fabric.* T. Stoward, London. Eng. Pat. 17,629, November 5, 1889. 4d.

FOR a long time past horseshair has been made into a fabric known as "hair-cloth" or "hair-repp" which is especially suited for cushions in railway carriages, &c., owing to its great wear-resisting properties. But it has one great drawback, viz., being of an open nature, it admits dust, vermin, &c. The patentee therefore "proofs" such fabrics on the underside, by any of the well-known methods of proofing, hereby obtaining a fabric which he states possesses many advantages and is suitable for various purposes.—H. S.

*An Improved Method of Treating Vegetable Fibres so that they will Spin more Easily and make Stronger Yarn, Thread, or Strand.* K. T. Sutherland and G. Esdaile, Manchester. Eng. Pat. 18,932, November 26, 1889. 4d.

THE fibres are put into a vat or bath containing a weak solution of carbonate of soda (hot or cold), worked there for three hours, washed, dried, and prepared for spinning. Fibres treated thus will "flock," and when artificially shortened, can be spun on cotton machinery. The spinning will be easier, and the yarn, thread, or strand stronger. (Compare this Journal, 1890, 856.)—H. S.

*Improvements in or relating to the Decortication of Rhea, Jute, and other Fibrous Vegetable Stems.* J. Longmore and W. L. Watson, London. Eng. Pats. 7389 and 7390, May 12, 1890. 8d. each.

THE chief parts of a machine for the above-named purpose are two rollers, the one serrated, the other smooth, and a cylindrical beater. These parts must be in as close proximity to one another as possible. The rollers bring the material under the action of the beater, the serrated roller being placed above the smooth one. A fixed bar upon which the stems of the fibrous materials are broken is placed between the rollers and the beater, and made to rest on the smooth roller which supports it against the blows of the beater. Its vertical surface is curved, to enable the beater to work quite close to it. The bar further serves the purpose of scraping off the material from the smooth roller. The material is both carried to the machine and removed from it by two travelling aprons, one of which rubs off from the smooth roller any particles, especially gummy fragments, which the bar may have failed to scrape off. The beater and the serrated roller can be made of segments, instead of one cylindrical piece, and it is advisable, to make the ribs or blades of the beater removable so that they may be easily changed when worn or otherwise damaged. The construction is varied by doing away with the bar and using instead of the smooth roller another grooved or serrated one.

In this case the beater acts directly against this roller. The stems to be treated are laid longitudinally on one of the travelling aprons, nipped by the rollers, and by them delivered to the beater. The rollers should be adjusted in such a way that the stems are neither dragged nor crushed between the rollers and the beater. By the action of the beater the woody interior of the stems is broken into fine pieces which are easily removed by shaking the stems. The great advantages of this machine are that the whole length of the stems is uniformly operated on, and that simplicity and cheapness of construction are combined with continuity and reliability of operation.—H. S.

*A New Vegetable Fibre for use in the Manufacture of Brushes.* W. S. Booth, Gloucester. Eng. Pat. 9781, June 24, 1890. 4d.

The petioles of the leaves of *Sabal palmetto* (cabbage palmetto) are taken, steeped in an aqueous alkaline solution until soft, and then combed or hackled, thereby separating the useful fibres from bark, fine fibres and other waste substances.—H. S.

*Improvements in Apparatus for Carbonising Material such as Wool.* A. Silberberg and C. Detering, Bedburg, Germany. Eng. Pat. 10,856, July 12, 1890. 6d.

The object of this invention is to avoid a great disadvantage connected with the usual carbonising apparatus, viz., the escape of acid vapours. For this purpose the carbonising drum is mounted on a hollow shaft, and this shaft is connected with a cylindrically-shaped retort for the evaporation of the acid, the latter being introduced by a supplying tube fitting into the centre of the front surface of the retort. All these parts revolve together with the carbonising drum. The heating apparatus is so arranged beneath the retort that the fire gases pass uniformly over the whole surface of the retort. The products of combustion escape into a smoke-flue above the retort. The end of the supplying tube is fitted with another tube at right angles to it, having a funnel at its end, in order to raise from a vessel underneath it, at each revolution, a certain quantity of acid which flows into the retort. To keep the latter closed, the funnel tube is bent like a gauge-tube.—H. S.

*A New or Improved Process of Obtaining and Bleaching Vegetable Fibres.* K. Trobach, Berlin, and G. J. Bruck, Leipzig, Germany. Eng. Pat. 12,689, August 13, 1890. 4d.

The ripe, dry vegetable fibres, particularly flax fibres, are first boiled in a soap solution, and afterwards in hot water, and then washed with cold water. The material is next steeped in a solution of potassium permanganate, whereby all incrusting substances, such as pectin, gum, colouring matters, &c., are oxidised and destroyed. The material is again washed in cold water, and the reddish-brown colour produced by the permanganate solution removed by placing the material for a short time in a bath of sulphurous acid solution, afterwards washing in cold water. By this treatment the fibres are completely freed from all incrusting substances, and only the straw is left with the fibres, and is removed in the usual way. The fibres thus obtained are long, pliant, and brilliantly white, and give silky, glossy yarns which are of greater strength than those produced by other methods.—H. S.

## VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

### PATENTS.

*A Process for Rendering Dry Alizarin Fit for Colouring and Printing Purposes.* C. Romen, Charlottenburg, Germany. Eng. Pat. 18,217, November 14, 1889. 6d.

The method by which dry alizarin (instead of the 20 per cent. paste usually employed) may be used for dyeing purposes, consists in dissolving the dry powder in an alkali and adding borax. The following quantities are given for dyeing 100 kilos., for which the bath must contain 2,000 litres of water. A solution is prepared of 2 kilos. of the dry powdered alizarin in 15–20 litres of water, 1.3 litres of soda lye of 38° B., and 300 grms. of borax. This is then added to the water and the alizarin is precipitated by adding 1.3 litres of hydrochloric acid of sp. gr. 1.15 and 400 grms. of acetic acid. The goods are then dyed in the ordinary manner. For printing purposes the process is a similar one.—T. A. L.

*A New or Improved Machine for "Blowing" or Steaming, Boiling, Cooling, Scouring, and Dyeing Woven Fabrics.* A. T. Clay, Rastrick. Eng. Pat. 19,377, December 3, 1889. 8d.

The material to be treated is wound upon a perforated cylinder which revolves in an air- and steam-tight box, and the air pumped out of the box through the hollow shaft of the cylinder. Then steam is introduced into the box through perforated pipes, and the pumping continued, thus drawing the steam through the fabric. The perforated cylinder is kept revolving during the whole process. The time of treatment varies according to the nature of the fabrics. It is stated that liquids may also be applied to the fabric in the same manner.—H. S.

*Improved Apparatus for Dyeing, Cleansing, Bleaching, and Drying Yarn in Cops, or in a similar condition.* C. Weber-Jacquel, Thann, Germany. Eng. Pat. 19,408, December 3, 1889. 8d.

It is well known to be an advantage for the dyeing, scouring, &c. of textile materials, especially of yarn cops, to force the reagents through the materials. The essential features of this invention are that the reagents used are not forced through the cops by pumps, and that the vat is not hermetically closed. This prevents the spoiling of the machinery as well as of the reagents, and enables a continuous control to be maintained over the whole process. The cops are carried by a spindle frame, placed in an open vat, and connected with a vessel which stands on a higher level, and can be closed hermetically. The liquid descends into the vat by its own gravity, or under the influence of compressed air, and is sucked back by means of an exhauster. This is repeated as often as necessary for the dyeing, scouring, &c. of the cops. The spindle frame consists of a series of concentric tubes which communicate with each other by radial tubes, the latter being connected with that supplying the reagent. The spindles carrying the cops consist of hollow perforated tapering tubes of any suitable material. The apparatus can also be used for gaseous reagents, in which case the vat has to be closed.—H. S.

*Improvement in the Process of Treating Textile Fabrics and Manufacturing Bagging from Jute Butts.* A. Gratz and B. Gratz, St. Louis, U.S.A. Eng. Pat. 11,005, July 15, 1890. 4d.

Two or three parts of borax, or soda, alum, sodium chloride, &c., are dissolved in seven or eight parts of water, and applied to bagging manufactured from jute butts, and to other fabrics, to bleach them. The fabrics, still damp, are then formed into bundles or rolls, and stored away in this

damp condition, when a chemical action takes place in the mass which effects the bleaching of the fabrics. It is stated that bagging from jute butts along with other fabrics are by this method better bleached than by any previously employed process, and that the fabrics are rendered fire-proof, softer and more pliable.—H. S.

*Improvements in Colour Printing.* H. E. Newton, London. From G. W. Turner, Brooklyn, U.S.A. Eng. Pat. 12,636, August 12, 1890. 8d.

The object of this invention is to provide an improved method for printing in colours, by which an impression in two or more colours may be taken upon paper or textile fabrics by one operation, and is in particular applicable to book and newspaper work, where speed is of paramount importance. The invention is especially adapted to web machines, but is also applicable to other classes of printing machines, with either curved or flat printing surfaces. To effect the object desired a printing form or plate is prepared having surfaces of different heights, the picture or other matter which is to receive a colour different from the body of the paper being preferably placed below the surface of the main portion of the plate. With this form an impression surface is used having corresponding faces of different heights arranged reversely to those of the printing form. The paper to be printed is fed in the usual manner, the impression being given by bringing the impression surface into printing contact with both the upper and lower printing surfaces by one operation. The inking of the main surface is effected in the usual manner. The ink for the depressed portion is supplied by a secondary roller carrying an inking pad corresponding in size and shape to the depressed portion of the printing form, and being so geared that it engages with the depressed portion of the form as the cylinders revolve. The depression necessary to avoid contact of the lower surface with the primary inking mechanism is so slight as to cause no injurious effect upon the paper in printing.—W. E. K.

*Improvements in the Process of Colouring or Decorating Paper and other Fabrics for Wall Coverings and for other Purposes.* T. Strahan, Chelsea, Mass., U.S.A. Eng. Pat. 12,900, August 16, 1890. 8d.

This invention consists in producing devices upon paper, &c. by discharging liquid or liquid colour against the surface of the fabric by means of any suitable atomising arrangement. The colour may be directly applied or may be produced by the chemical action of the liquid upon paper coated with a suitable reagent. The jets of the nozzles of the atomisers may also play either continuously or intermittently upon the paper according to the effects desired, and two or more colours may be employed. The paper to be coloured is carried slowly along in front of the nozzles of the atomisers and at a suitable distance.—W. E. K.

*Improvements in Bleaching.* H. Thies, Laaken, and E. Herzig, Rentlingen, Germany. Eng. Pat. 12,950, August 18, 1890. 8d.

This invention relates to the bleaching of cotton and other vegetable fibres, and has for its purpose the economy of time, working power, steam and chemicals. The calico (or other vegetable fibre) is first impregnated with an acid solution, containing, per litre, 10 grms. of sulphuric acid, 16 grms. of hydrochloric acid, and 0.5 gm. of hydrofluoric acid. After lying for four hours it is steamed for half a minute and then passed into a washing machine containing a  $\frac{1}{2}$  per cent. solution of soda at a temperature of 50° C., and afterwards allowed to lie for 12 hours. The cloth is next washed in a washing machine with water containing chloride of magnesium or other alkaline earth compound, whereby the alkaline earth is deposited on the fibre by the action of the alkali contained in the cloth. The excess of wash-water is removed by squeezing-rollers, and the cloth brought into a specially-constructed scalding vessel or kier. Below the false bottom of the kier is a receptacle or chamber, and connected with this is a pump by means of

which the liquor may be drawn out of the receptacle and forced through the tubes of a boiler and then into the kier again at its top. Into this lower receptacle there also passes a perforated steam pipe, the steam passing into a second pipe which leads out into the air or to the condenser. The pressure in the lower receptacle is constantly varied by receiving or discharging steam, whereby the circulating liquid passes at a higher rate of speed through the fibrous material. With this accelerated circulation, moreover, the lye is concentrated by constant discharge of steam or water through the pipe into the air. When the kier has been filled with cloth and closed the contents are steamed for about  $1\frac{1}{2}$  hours at a temperature above 100° C. by means of the tube system contained in the tubular boiler. A charge of caustic soda is then introduced into the kier (to 1,000 kilos. of cotton 600 litres of solution prepared from 50 kilos. of soda ash, causticised with lime, and having dissolved in it 10 kilos. of resin), and this is circulated by means of the pump. By means of the tubular boiler the temperature of the circulating liquor is maintained at about 125° C., the operation being continued for about five hours. The cloth is then washed in the kier with boiling water, and finally "chemicked" and soured in the usual way. It is claimed that a cellulose of perfect chemical purity is thus obtained, which can be used not only for garments, but also for sanitary purposes and for the preparation of chemical products, as for instance gun-cotton.—W. E. K.

*Certain New and Useful Improvements in Dyeing Apparatus.* S. Pitt, Sutton. From A. Smith and Sons Carpet Company, Yonkers, U.S.A. Eng. Pat. 13,048, August 19, 1890. 11d.

This invention has for its object the reproduction by machinery of the operations of manual hand-dyeing. It consists of certain mechanism by means of which the hanks of yarn, hanging upon poles, may be shifted in the dye-liquor, and, if desired, trailed through the liquor; and when the entire invention is used the hanks of yarn hanging upon any one pole are not only shifted in the dye-liquor, but each pole of a series upon which hanks are hung in a dye-vat has the hanks upon it shifted in succession so that all the hanks of yarn which are being dyed at any one time in the same dye-vat are shifted in the dye-liquor the requisite number of times for the completion of the dyeing operation. For the mechanical devices by which this is effected the specification and accompanying 13 drawings must be consulted.—W. E. K.

## VII.—ACIDS, ALKALIS, AND SALTS.

*The Reduction of Alkaline Sulphates by Hydrogen and Carbon.* Berthelot. Bull. Soc. Chim. [3], 4, 234—238.

It is usually stated in text-books that hydrogen reduces alkaline sulphates at a red heat, as, for example, in the following equation:  $\text{K}_2\text{SO}_4 + 8\text{H} = \text{K}_2\text{S} + 4\text{H}_2\text{O}$ . The author, however, finds that sulphuretted hydrogen always accompanies the aqueous vapour, and that the residue contains caustic alkali. In fact, the initial stage of the reaction is more correctly represented thus:—

This reaction is exo-thermic. The reduction takes place at about 500° C. But at this temperature the potassium sulphhydrate produced is decomposed, under the influence of the external heat, into potassium sulphide and sulphuretted hydrogen:  $2\text{KHS} = \text{K}_2\text{S} + \text{H}_2\text{S}$ , 9.5 calories being absorbed per molecule of KHS. The formation of sulphuretted hydrogen is hastened by the current of aqueous vapour and excess of hydrogen. A portion only of this sulphuretted hydrogen passes on, the remainder reacting with the potassium hydrate forming sulphhydrate, which is, however, not stable at a high temperature.

The heat liberated in this reaction is +12.8 calories. There is thus a tendency for all the alkaline metal to be converted into sulphide; but, on the other hand, the alkaline sulphide is decomposed by the aqueous vapour, an alkaline hydrate and sulphhydrate being regenerated with the liberation of +5.8 calories.

Between these various reactions a certain equilibrium is established, depending on the tendency of the bodies present to interact with evolution of heat, due to their internal energy; and on the decomposition of the sulphhydrate by the external heat. Meanwhile the production of water and sulphuretted hydrogen continues until all the alkaline sulphate is decomposed and all the sulphhydrate dissociated. The final result is a mixture of alkaline sulphide and hydrate, of which the relative proportions depend on the more or less prolonged contact of the aqueous vapour and sulphuretted hydrogen with the solid matter. A small quantity of alkaline polysulphide is also amongst the products of the reaction. Its formation is due to the decomposition of some of the sulphuretted hydrogen into sulphur and hydrogen. A part of this sulphur condenses in the upper portion of the tube; the remainder combines with the alkaline sulphide. As potassium sulphide is sensibly volatile at the temperature employed, a small quantity sublimes into the upper end of the tube, where it combines with the condensed sulphur, forming a reddish ring.

In studying the action of carbon on alkaline sulphates it is well to consider first the effect of carbon monoxide on these salts. The reaction is exceedingly simple,—

the heat liberated being +33.2 calories. In the case of sodium sulphate, +35.2 calories are disengaged. The temperature required to effect reduction is high, being about 700°–800° C. Purified dry charcoal acts on alkaline sulphates in a precisely similar manner and at the same temperature, carbon dioxide and an alkaline sulphide being formed. There is no doubt that carbon does not exert a direct reducing action on alkaline sulphates. Carbon monoxide is probably at first formed by the agency of the atmospheric oxygen present in the apparatus, or that contained in the charcoal. The carbon dioxide produced by the interaction of this carbon monoxide and the alkaline sulphate, reacts with the excess of carbon present, again forming carbon monoxide. The latter reduces a further portion of sulphate; and in this manner the action proceeds, the amount of gaseous carbon being increased during each cycle of reactions, so that a trace of carbon monoxide suffices to start the reduction.—H. T. P.

*Report on Acetic Acid.* Report of the Central Laboratory of the Italian Customs Department, 1886–1889, 307–313.

In order to protect the native industry of the manufacture of acetic acid from alcohol, the Italian Government raised the import duties recently (Decree, July 26th, 1888) on acetic and pyroligneous acids. The following duties are now in force: For liquid acetic acid, impure, 1 lira per quintal; for acid containing 10 per cent or less, 15 lire per quintal; from 10–50 per cent., 90 lire per quintal; above 60 per cent., 180 lire per quintal; and crystallised acetic acid, 200 lire per quintal (Journal, 8, 352). It is further laid down that “acetic acid is considered pure even though it is coloured artificially, though not containing substances of empyreumatic and bituminous odour characteristic of pyroligneous acid.”

The duty on crude pyroligneous acid is 2 lire per quintal, and it is defined as follows: “by crude pyroligneous and acetic acid are meant those which contain substances possessing empyreumatic and bituminous odours, arising from the distillation of wood, and of an acidity less than 50 per cent., calculated in terms of pure acetic acid.”

The Department points out that controversies frequently arise as to whether a product is to be classed as a *liquid* or *impure acid*, and that the high duties are an incentive to fraud, and that endeavours are and will be made to pass as pyroligneous acid concentrated acid of a considerable degree

of purity, such as are obtained after a second or third purification; these are often colourless, but are sometimes coloured artificially with caramel. As the regulations state distinctly that by an impure acid is meant crude pyroligneous acid, it obviously excludes acids obtained by the decomposition of purified acetates or by the method of Rothe, yet the laboratory have received samples of this nature. This point is insisted upon on account of a violent attack (Chem. Zeit. 13, 1473 and 1483) upon the Director of the laboratory for having classed as liquid acids, acids which were coloured and had a slight empyreumatic odour.

A table of analyses of samples received is appended to the report.—V. H. V.

#### *Report on Caustic Potash and Soda, Alkaline Carbonates.*

Report of the Central Laboratory of the Italian Customs Department, 1886–1889, 314–318.

The tariff distinguishes between pure and impure caustic soda and potash, the former paying 5 lire, the latter 0.50 lira per quintal; no such distinction is drawn in the case of sodium carbonates, whether natural or manufactured, but it is expressly laid down that “soda containing a quantity of sodium chloride greater than 60 per cent. is to be considered as sea-salt, and cannot, therefore, be introduced into the kingdom.” Determinations were made of the total alkalinities, the sodium hydrate, carbonate, chloride, and sulphate. Certain residues from the Leblanc process were classified as “concime” (refuse), in accordance with the report. Controversies arose regarding the classification of certain importations from France, as to whether they should be regarded as sodium carbonate, with a *differential* duty of 2 lire per quintal, or as impure caustic soda, subject to the *general* duty of 0.50 lira per quintal. As these contained a comparatively large proportion of carbonate (56–68 per cent.) and a small proportion of hydrate (3.5–10.5 per cent.), they were classed under the former heading.—V. H. V.

#### *Report on Potassium and Sodium Nitrates, Stassfurt Salts,*

yc. Report of the Central Laboratory of the Italian Customs Department, 1886–1889, 319–339.

ACCORDING to the tariff, every mixture of soluble salts containing a proportion of sodium chloride greater than 25 per cent. is to be considered as sea-salt, and its *importation is, therefore, prohibited*. Potassium chloride from Stassfurt is classed as manure; and from information supplied by the Syndicate out of 119 million kilogrammes of potassium chloride manufactured at Stassfurt in 1886, 4.2 million kilogrammes were sent to Italy. It is used in that country as manure, for the manufacture of nitre, and as a substitute for common salt in freezing mixtures. Carnallite, kainite, &c. are also classed as manures.

In cases of dispute concerning mixtures defined in the tariff as “salts for artificial sea baths,” the Direction determined the proportions of moisture, insoluble residue, sulphuric acid, total chlorine, magnesium, potassium, and sodium.

*Potassium and Sodium Nitrates.*—The former is subject to a duty of 3 lire per quintal, the latter is classed as “crude,” free of duty, and refined, with a duty of 3 lire. As a result of analyses by various chemists and of those performed in the laboratory, it was considered that refined sodium nitrate should contain 94–97 per cent. of the pure salt. Allusion is made to the frequent sophistication of sodium nitrate with chlorine. In both salts the proportions of water, insoluble residue, chloride, sulphate, and iodide were determined. It appears that several importations of salt and saline mixtures were confiscated, and the reports of analyses sent to the Minister.—V. H. V.

*Commercial Condition of Persia.* Board of Trade J. November 1890, 604.

See under X., page 1040.

## VIII.—GLASS, POTTERY, AND EARTHENWARE.

### PATENTS.

*An Improved Manufacture of Vitreous Material suitable for Artificial Marble, Stained Glass, and Analogous Objects.* F. R. Rostaing, L. A. Garehey, and N. E. Geille, Paris, France. Eng. Pat. 16,696, October 22, 1889. 6d.

THE waste glass of suitable size and of various colours and shapes is placed in moulds lined with silica or tale, &c., and the whole fired. A coherent mass is produced, which is dressed and cut, forming an irregularly-coloured block. The lower surface, *i.e.*, that which has rested on the mould, is rough from having been incompletely fused, and is left in this condition to enable the material to be more readily attached to the walls. Designs in relief, &c. can be obtained by pressure whilst the block is still plastic. If a suitable mould be prepared with movable partitions, then pieces of glass can be arranged in such a way that, upon firing, a stained glass window is produced, the necessity of using "leading," as in the ordinary process, being thus obviated.

—S. G. R.

*An Improvement in the Manufacture of Antique and other descriptions of Sheet Glass and Improved Apparatus in connection therewith.* J. G. Sowerby, Gateshead-on-Tyne. Eng. Pat. 17,565, November 5, 1889. 6d.

THE glass is blown into a jointed mould, furnished with a vertical slit. The cylinder thus produced is very thin at top, bottom and side at the opening of the slit, and can be easily cracked off at these points. It is then re-heated and flattened into sheets in the usual way. The cutting down, ordinarily effected with a diamond, is thus done away with. The specification is illustrated with drawings.

—S. G. R.

*Improvements in Etching upon Glass.* B. Z. Meth and H. Kreitner, Berlin, Germany. Eng. Pat. 12,155, August 2, 1890. 4d.

A SOLUTION is prepared by mixing together in proper proportions ammonium fluoride, sodium chloride and sodium carbonate, and then placing the mixture in a gutta-percha bottle containing fuming hydrofluoric acid and concentrated sulphuric acid. In a separate vessel made of lead, potassium fluoride is mixed with hydrochloric acid, and a little of this solution is added to the former, along with a small quantity of sodium silicate and ammonia. Some of the solution is dropped upon a rubber pad, and by means of a suitable rubber stamp bearing the design to be reproduced, is transferred to the glass vessel which is to be etched.

—S. G. R.

## IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

*Magnesia in Portland Cement.* Dyckerhoff. Thonind. Zeit. 14, 452.

THE author has examined samples of cement containing proportions of magnesia ranging from 1.93 to 21.24 per cent. A normal Portland cement containing 1.93 per cent. of magnesia showed a regular increase in strength on keeping; the tensile strength of briquettes made of a mixture of 1 of cement to 3 of normal sand was 28.5—28.7

kilos per sq. cm. at 12—24 months. The remaining five samples when tested similarly all showed an increase in strength up to six months, the results being as follows:—

Per cent. MgO . . .	6.23	11.36	10.82	17.80	21.24
Tensile strength . .	26.5	25.5	22.5	22.5	15.0

The last three cements retrograded from this point more or less rapidly; the first two continued to increase in strength up to 12 months, and then began to go back. The speed of retrogression depends on the temperature at which the cement has been burnt. The sample containing 10.82 per cent. of magnesia, which was more lightly burnt than the others, diminished more rapidly in strength. Samples 1—3 showed cracks after three years, while the remaining two failed in this respect after two years. Pats made of sample 5 (21.24 per cent. of magnesia) unmixed with sand did not give signs of failure when subjected to the ordinary water-test until a year had elapsed. Besides these results with cements made of dolomitic material, the author found that strongly ignited magnesia added to a normal cement produced a powerful and prolonged expansion of the test pieces.—B. B.

*The Frost-Resisting Power of Natural and Artificial Building Stones.* Bauschinger. Thonind. Zeit. 14, 467.

EXPERIMENTS have been made with 21 different kinds of natural building stones, 3—6 test pieces of each being used. Their tensile strength, dry and wet, their capacity for absorbing water, their alteration in volume, tensile strength and behaviour towards water after freezing and thawing 25 times, and their specific gravity, were determined. Out of this number of samples, ranging from limestone to sandstone, only six were found to resist repeated freezing, *viz.*, one of dolomite, one of diorite, and four sandstones. Four other samples were found to resist freezing fairly, but not absolutely; but of 11 samples of artificial stone similarly tested, only three were found thoroughly unaffected, while eight proved fairly resistant.—B. B.

*Liability to Error in Mixing Cement with Wet and Dry Sand.* Candlot. Monit. Ceram. et Ver. 21, 144.

FERET has pointed out the possibility of serious mistakes in the proportions of mixtures of cement and sand due to a disregard of the condition of the sand—whether wet or dry. This is demonstrated by the following table:—

	Kilos.						
Quantity of water added to 100 kilos. of dry sand . . . . .	..	0.5	1	2	3	5	10
Weight of a cubic metre of moist sand	1,458	1,310	1,238	1,213	1,209	1,208	1,266
Weight of dry sand contained in 1 cubic metre of moist sand	1,458	1,304	1,226	1,189	1,174	1,151	1,119

It is obvious that the addition of comparatively little water largely increases the bulk of the sand,—out of all proportion to the amount used. For instance, 2 per cent. causes the weight of a cubic metre of the moistened sand to decrease 269 kilos., that is to say, 18.5 per cent. of the original weight. Such differences would cause great fluctuations, hitherto generally overlooked, in the composition of mortar mixtures intended to be of a certain strength.

—B. B.

*Corrosion of Zinc in Contact with Brick.* Iron, 36, 80.

UNDER some conditions, sheet zinc, when in direct contact with brickwork, appears to suffer to an appreciable extent from rapid corrosion. It has been found in the Berlin city

market halls that a portion of the zinc work supported upon brick walls was deeply pitted at a number of places, this being particularly the case where the metal was close to the bricks. Chemical examination of the bricks showed that they contained as much as 1.14 per cent. of soluble salts, capable of producing the destructive effect in question, and stimulated to more energetic action by moisture. The proportion of such salts, of course, varies with different kinds of bricks, while in some there may be nothing to induce any such corrosion.

*Report on Stones, Earths, Glasses, &c.* Report of the Central Laboratory of the Italian Customs Department, 1886—1889, 412—426.

POLISHED precious stones, such as rubies, emeralds, diamonds, pay 14 lire per hectogramme; but agates, opals, onyxes, pay 9 lire per kilogramme; while sham stones classified as glasses, crystals, smalt, pay 50 lire per quintal. Questions arose as to whether certain polishing materials made with powdered corundum were to be regarded as "polished precious stones" inasmuch as the report mentions corundum under this head; it was, however, decided that though corundum in the form of sapphires and rubies has an especial commercial value, yet, considering the common occurrence of this mineral, these materials should be classed as compounds of emery with bitumen, &c., and would thus be assessed as terra-cotta (Official Bulletin, 25, 883). It was also decided that infusorial earth came under the head of "fossil starch" and thus free of duty, and that powdered quartz, not specially mentioned in the report, should be classed as "natural sand."

Substances declared as non-metallic minerals such as native strontium and barium carbonates were considered to be rightly classified and not liable to the duties on chemical products not specified.

In order to decide whether materials declared as stones, earth, &c., were not in reality cements or hydraulic limes, and thus subject to a duty of 1.25 lire per quintal, the Direction determined (1) the specific gravity by the volumeter of Schumann, and (2) the amount of free alkali extracted from a given weight of the cement by a given volume of water according to the directions laid down by R. and W. Fresenius (Feichtinger, Technologie der Mörtelmaterialien, 185).

To judge of the hardening properties of mortar and cements, the criteria set forth by the College of Experts (Report, 1884, 139) were adopted.

#### PATENTS.

*Improvements in the Manufacture of Portland Cement from Hard Limestone.* W. T. Timewell, Bristol. Eng. Pat. 15,737, October 8, 1889. 4d.

HARD limestone such as the hard mountain limestone of Somersetshire and Devonshire is powdered sufficiently finely to allow of 75 per cent. passing through a sieve having 6,400 meshes to the square inch, mixed with "silicated clay" and water, ground, dried and burnt in the usual way. "Continuous running mixtures and the uncertainty of results incidental to the soft chalk processes" are said to be done away with, and "the production of a cement of high and regular quality" ensured.—B. B.

*Improvements in Resistant Coverings for Battery-Room Floors or Surfaces, Laboratory Floors, and like uses.* R. E. R. Crompton and B. H. Jenkinson, London. Eng. Pat. 17,623, November 5, 1889. 4d.

POWDERED slate is mixed with Trinidad asphaltum by the aid of heat, and the composition spread on the surface to be protected. Finely-powdered slate may afterwards be dusted on, and the floor finished by polishing. The process may also be used for the manufacture of vessels to hold acids and similar corrosive substances.—B. B.

*Improvements in the Manufacture of Building Material for Architectural and other Purposes, and of a Composition for use in Connexion therewith.* H. A. Bassett, Birmingham. Eng. Pat. 17,758, November 7, 1889. 6d.

TWO hundred parts of a viscous mixture of glue and water are mixed with 40 parts of oil such as rape or raw linseed and 12 of sodium carbonate, the whole being heated and agitated. In making such things as artificial stone 6½ parts of this mixture are taken and 16 parts of water and 9 of borax added thereto. One part of the resulting mixture is added to 6 parts of water, 1 part of white china clay, and enough plaster of Paris to give a stiff paste which can be moulded and polished.

For the preparation of plaster for walls, &c. 6½ parts are added to 16 of water, 96 of plaster of Paris, and 1 part of air-slaked lime, the mass dried and mixed with 9 parts of powdered borax; one part of the dried mass is mixed with 14½ parts of plaster of Paris, 40 parts of building sand, 1½ parts of wood dust and enough water to form a paste, which is applied as a first coat. The material for the second coat is made by using 10 of the dried composition, 112 of plaster of Paris, 140 of fine sharp sand, 10 of white china clay or powdered Bath stone, and enough water to form a fairly stiff paste. Similar compositions for other purposes may be used.—B. B.

*New or Improved Flexible Material applicable as a Substitute for Wood or Leather, and Process of Making the same.* W. P. Thompson, Liverpool. From C. Heepe, Boekenheim, Germany. Eng. Pat. 18,730, November 22, 1889. 8d.

See under XIV., page 1048.

*Improvements in the Treatment of Slag for a Variety of Important Uses, as Building Blocks, Paving Blocks, and the like.* S. G. T. C. Bryan, Birmingham, U.S.A. Eng. Pat. 8606, June 3, 1890. 6d.

TEX to 20 per cent. of anhydrous alumina is added to blast-furnace slag in the fused state, the mixture agitated and given a rotary motion by suitable mechanical means. It is claimed that the unfused impurities and the occluded gases are got rid of by this treatment, and that the produce is sufficiently homogeneous to be useful as a building material.

The moulds in which the treated slag is cast may be lined with wood, paper, or "carbon composition," the object of this device being to prevent "the contraction of the slag closing the cells near to and on the surface of the moulds," and to thereby increase the toughness of the product.—B. B.

*A Method of Colouring and Polishing Calcareous and other Stones, and producing Variegated Effects thereon in One or more Colours.* T. Breakell and J. W. Breakell, Manchester. Eng. Pat. 10,002, June 28, 1890. 4d.

THE process used may be understood by the following example:—To produce a red shade the stone is heated to about 200° F. and a mixture of "gum dragon and resin" applied to the surface, after which the stone is again heated for about two hours. The stone after cooling is cleaned and polished. The combination of resin with the colouring matter is claimed as novel. For brown shades boiled linseed oil in conjunction with tar and resin is also claimed. For variegated effects the stone is coloured as described above, then rubbed down until portions which have absorbed the colouring matter less deeply are exposed and treated with another colour in the same way as before, the parts already coloured absorbing but little of the new pigment. An imitation of marble may be produced by first painting or printing a pattern in a solution of "white gum lac" in naphtha, which serves to protect the stone from the colouring matter subsequently applied.—B. B.

## X.—METALLURGY.

*Titanium in Blast Furnaces.* A. J. Rossi. J. Amer. Chem. Soc. **12**, 91—117.

THE paper deals with the following questions:—(1.) Is titanium an element so obnoxious that ores, otherwise excellent, easily and cheaply obtained, should be rejected on account of its presence, even in small or limited quantities? (2.) Is it the excess of titanium which has caused the general prejudice there exists in America against the use of ores containing this element, and is this prejudice justifiable in all cases? (3.) Are there any limits within which the presence of titanium would pass unobserved, and would not influence the working of the furnace?

It is pointed out that titanium occurs to a varying extent in all the materials that enter the blast furnace, and a detailed summary of the percentage of the metal found in the ores used in the United States, Norway and Sweden, Russia, France, and England is given. A similar summary of the per cent. of titanium found in pig irons from many localities is also given. In the case of American pig this varies from 0.03 to 0.52 per cent. of  $TiO_2$ . A number of extracts from papers already published on the subject follows, and from an examination of the whole collated material the author draws his conclusions as follows:—

(1.) Titanic acid is not necessarily and always a cause of trouble in the blast furnace, even if present in large quantities.

(2.) In small quantities its presence appears to have been ignored for many years, and furnaces have run and do run to-day with ores rich in iron containing as much as 0.3 per cent. to about 1 per cent. of  $TiO_2$  in the charges without apparent trouble of any kind, these ores being smelted alone or in admixture with others more or less free from titanium.

(3.) When present in very notable quantities it has a tendency to render the slag pasty, and clog a furnace with titanium deposits; but with proper care and fluxes very little different from those ordinarily used, such ores may be smelted cleanly and profitably, though perhaps less economically than other ores.

(4.) Lean ores containing 40—48 per cent. of titanic acid have been successfully smelted, but at a relatively greater expenditure of combustibles. This refers especially to the smelting of Scandinavian ilmenite in charcoal furnaces, whilst it is pointed out that certain natural compounds of titanium, such as sphene, calcium silico-titanate, and kailhaute, which contain from 28—40 per cent. of  $TiO_2$  are perfectly fusible in a blast furnace. Reference is also made to an experiment of Professor Forbes, in which an ore containing 39.20 per cent. of  $TiO_2$  was smelted without admixture and without giving any trouble in the furnace. About 1—2 per cent. of the titanic acid remained in the pig, whilst the slag contained 36.18 per cent. of  $TiO_2$ , and approximated natural sphene in composition.

(5.) It cannot be maintained, in presence of the European and limited American practice with titaniferous ores, that inappreciable or very small quantities of titanium are objectionable or sure to cause trouble in the furnace; in fact the metallurgy of all kinds of titaniferous ores has been a success in Europe.

(6.) To decide what are the limits at which an ore containing titanic acid would require a modification in the ordinary charges used with ores free from it, could only be arrived at by direct experiment. Another practical question is to what extent the extra expenditure of combustibles, if any, would be compensated for by the special qualities claimed for the pig metal obtained? It is pointed out that the titaniferous iron ores are exceptionally poor in or free from phosphorus and sulphur (several analyses of American and other ores are given bearing out this point), and are therefore specially suited for the manufacture of Bessemer steel, so that the metal obtained from such ores has an increased value, apart from any particular beneficial effect due to the presence of titanium.

In conclusion, the author directs the attention of American metallurgists to their disregard of the value of titaniferous

ores, and states that hematite, &c. is often imported from great distances in cases where titaniferous ores are at hand more free from phosphorus and as rich and richer in iron than the imported ores.—C. A. K.

*Blast-Furnace Slags, and the Fusibility of Silicates.* A. J. Rossi. J. Amer. Chem. Soc. **12**, 189—214.

THE composition of blast-furnace slags affects their fusibility, and bears a close relation to the grade of iron obtained. Many circumstances may modify the results, and to say that a slag of a certain composition and fusibility will invariably correspond to a stated grade of iron is impossible.

Reviewing a number of tables, the results of experiments by Percy, Caron, and Berthier, and quoted in Vathaire, *Les Hauts Fourneaux*, the author points out that of the compounds which silica can form with lime and alumina, or alumina and magnesia, or magnesia and lime, as a general rule, the less basic they are the more fusible they become, until a certain limit of acidity is reached, and that amongst them, when the quantity of silica is above 40 per cent. and not over 60 per cent., the compound becomes as much more fusible as the percentage of silica is above the first figure, varying between 40 and 60, beyond which last limit the silicate appears to fuse again with more difficulty. The more complex a silicate becomes, the more fusible is it. If we consider that oxide of manganese, ferrous oxide, and alkalis are always met with in slags in proportions which may reach 5—7 per cent., that the alkalis, in very small quantities, increase considerably the fusibility of even the most refractory silicates, it can be better understood why injudicious charges of limestone do not necessarily produce injurious effects. A slag, for instance, which if based on a certain per cent. of alumina and lime would have been refractory, acquires a greater fusibility owing to the presence of manganous and ferrous oxides, alkalis and magnesia, derived from the limestone.

From a comparison of the equivalents of the various bases, the author points out the inconsistency of using lime in excess as a flux; it is the most expensive fluxing agent, and the one of which the largest quantity is needed. More of it is necessary than of magnesia; hence a *dolomite* is preferable to a *calcite*.

Analyses of slags are given, and the properties of the slags are discussed in explanation.

It is recommended, in order to be able to compare slags with one another directly, that all bases be calculated to their equivalent in lime. The type of a slag is thus at once known, together with its properties generally.—T. L. B.

*French Antimony Mines.* Moniteur des Produits Chimiques.

THE antimony mines of Montignat, in the Department of the Allier, which had been abandoned since the beginning of this century, are now again being worked successfully. The present exploiters are Messrs. Lassalle and Brulot, of Montluçon, and about 400 tons of the antimonial ore were extracted during the last 12 months. The Montignat ore was famous in the beginning of this century for its high quality. It is said to be quite free from arsenic, and to contain only traces of iron.

*Nickel Steel.* Engineering and Mining Journal, **50**, 355.

THE second stage of the Annapolis trial of armour plates resulted in still further establishing the superiority of the nickel-steel alloy for such defensive work. The tensile strength of the nickel-steel plate was such that though penetrated by the shots no cracks were developed in the plate. The all-steel plate was divided into quarters by four cracks running from the centre hole to the holes made near the four corners and thence to the outside of the plate. The Cammell compound plate may be said to have been entirely broken up. The nickel-steel alloy, of which the plate was composed, is said to contain less than four per cent. of nickel.

The question of a market for a largely increased production of nickel which was so much questioned last year may be said to be definitely settled by these trials, as in addition to the European demand a bill has been introduced and immediately passed, by the House of Representatives, at Washington, appropriating 1,000,000 dols. to enable the secretary of the navy to buy nickel ore and nickel matte for use in the production of steel armour for the new armoured cruisers.

*The Production of Platinum.* Board of Trade J.  
November 1890, 558.

It is announced from Mexico that M. Flavio Lobato, mining and chemical engineer, has discovered platinum in certain ores extracted from the mines of Las Yedras, in the State of Sinaloa. This news, if it is confirmed, will be of enormous importance to industry, more particularly as platinum is becoming scarcer, and realises an abnormal price.

The platinum mines, situated in the Oural mountains, contain, says the *Journal de la Chambre de Commerce de Constantinople*, important auriferous deposits; until recently gold in large quantities constituted the chief mineral working, and platinum was obtained at the same time without large supplementary expenditure. The richness in gold of the chief mines, Nisknee-Taglisk, and Gord-Blagodot has much diminished, and the preparation of platinum has become more difficult; such seems to be the explanation of the high price of platinum. A large number of miners have abandoned the mines, and have established themselves on the works of the Trans-Siberian railway.

*Discovery of Quicksilver in Austria.* Board of Trade J.  
November 1890, 573.

THE *Neue Freie Presse* reports the discovery of what promises to be a rich quicksilver mine at the little market town of Wippach in Carinthia. As long as 20 years ago children, while playing near the Wippach at low water, had been known to find the metal. Little attention seems however, to have been paid to the circumstance until recently, when the visit to the neighbourhood by a mining engineer afforded Chief Justice Dolowz an opportunity of drawing attention to the fact, which was subsequently verified by a number of well-known officials from Trieste, who, on visiting the spot, succeeded with little trouble in getting quicksilver. It is said that as the metal is to be found at a depth of only one metre, mining operations could be prosecuted on the surface. The discovery of quicksilver at so slight a depth is phenomenal from a geological point of view, the metal being usually found in old geological formations.

*Mines and Mining Interests in the State of Sonora.*  
Board of Trade J. November 1890, 582.

No copper mines are worked in Sonora, owing to the low price of that metal, and the owners of mines of that class have suspended all work on them. Veins of iron, antimony, and lead, which exist, remain undeveloped.

During the year cinnabar was discovered about 150 miles from Guaymas, in the district of Ureas, and ore has been found yielding 30 and 50 per cent. These deposits are being prospected, and have been bonded, it is stated, to an English company. The owners have, by a crude process, extracted 20 flasks of quicksilver from the ore. These deposits of cinnabar are the first that have been discovered or worked in this Consular district.

The plumbago mines, near the line of the Sonora railway, owned by an American company, are being worked. A small quantity of this mineral is shipped monthly to the United States.

*Commercial Condition of Persia.* Board of Trade J.  
November 1890, 604.

THE following particulars are taken from a report by the Dutch Consul-General at Teheran, and published by the Dutch Government (*Verzameling van Konsulaire en andere Verslagen*, 1890. *Teheran*):—

It is estimated that Western Europe exports to Persia every year goods having an average value of 4,000,000*l.* Persian exports are probably not so important, but in the absence of all statistics it is difficult to say. Persia is rich in natural products of all kinds. In elements of mineral wealth copper comes first; there are many copper mines in the north range of the Elburz near Teheran, as well as in the districts of Tabriz and Kasmin. Copper is the metal which is most used in the country, the inhabitants make almost all their utensils of it. The ore is very rich. Hitherto only a few mines have been worked; there are no rolling mills in the country, and the sheet copper has to be imported. The iron mines are at present of no value, although it is hoped that in connexion with a new concession from the Imperial Bank, some alteration will be made. Near Teheran there are some very rich iron mines, with an ore containing 70 per cent. little sulphur, and no phosphorus. Cobalt of very good quality is found at Kaschan, and arsenic at Kasuin, and at various places in Kurdistan; lead ore, containing manganese and silver, at Kerman and on the north side of the Elburz mountains; sulphur in various places. There is abundance of salt and saltpetre, as well as antimony, alum, borax (to the north-west of Kerman), potash, marble, coal, and asbestos, and on the road from Teheran to Tabriz quicksilver is found. Petroleum occurs in various places, and in particular at Schoester and Bender-Bashir. The Persian petroleum has a small specific weight. Coal is found in the north, in the south, and particularly to the west of Bender-Bashir. The quality of the Persian coal is not particularly good.

PATENTS.

*Improvements in Processes for treating Tinned or Galvanised Scrap Iron.* A. J. Campion and J. E. Temison-Woods, London. Eng. Pat. 14,462, September 13, 1889. 6*d.*

TINNED or galvanised scrap iron is pressed into cakes, and heated in a reverberatory furnace with nitrate or carbonate of sodium and oxide of manganese, with or without the addition of powdered felspar or granite. The iron is then withdrawn, and hammered or rolled. The metals in the slag can be recovered by any suitable means. The oxidation of the tin or zinc in the scrap can also be effected by blowing air through the heated metal. The strength and toughness of the iron can be increased by adding a small quantity of chrome ore to the charge. The nitrate of sodium and manganese oxide can be added by dipping the compressed metallic cakes into a hot saturated solution of the nitrate in which the manganese oxide is suspended.

—H. K. T.

*Improvements in the Extraction of Tin and other Products from the Refuse Slags and Débris of Tin-Smelting Furnaces.* A. J. Campion, London. Eng. Pat. 15,226, September 27, 1889. 6*d.*

TIN slags and refuse from tin-smelting furnaces are smelted with coal or coke and fluorspar, limestone, granite, or granite products such as felspar, quartz, &c., with the addition of rock salt or sodium sulphate for the purpose of forming a reducible silicate of tin. Slags from foreign ores which are rich in silica require the addition of alkali makers' "tank waste." The impure tin obtained is remelted, and nitrate of soda is added. Iron and arsenic are oxidised and form a slag, and tin, nickel, and cobalt are left. The two latter solidify, first forming "spieess," and the fluid tin remains on the top. The impurities in the metal can be also oxidised by blowing air through the mass. Impurities in "tin plate makers' waste" or "scruff" can be oxidised in the same way.—H. K. T.

*Improvements in the Treatment of Gold-bearing Quartz and other Minerals for facilitating their Reduction to Powder.* W. C. Taylor and T. N. Kirkham, London. Eng. Pat. 15,970, October 10, 1889. 6d.

THE ore is heated to redness in a reverberatory furnace, and is raked through openings in the side of the furnace into a tank of water. By this means the minerals are said to become so friable that they can be at once passed through crushing rollers.—H. K. T.

*A New Metallurgical Dry Process.* J. B. Alzagaray, Porto, Portugal. Eng. Pat. 16,776, October 24, 1889. 6d.

INSTEAD of converting minerals into fusible silicates to allow of their reduction by carbon, they are fused with carbon and alkaline salts, viz., common salt, sodium sulphate, or black ash, the temperature being carefully regulated so that only one metal is reduced at a time. A number of theoretical proportions of ingredients are given. The process is carried out in the Baxeres furnace (this Journal, 1890, 950).—H. K. T.

*A Method of Recovering Float Gold.* E. A. Cowper, London. Eng. Pat. 16,868, October 25, 1889. 6d.

WHEN crushed gold-bearing minerals are washed, small particles of gold float on the surface of the liquid and are lost. To cause the gold particles to sink, jets of steam are made to impinge on the surface of the liquid, the gold particles become wetted, and sink through the liquid.—H. K. T.

*Improvements in the Manufacture of Alloys of Iron and Aluminium and Alloys of Steel and Aluminium.* S. Pearson and J. H. Pratt, Birmingham. Eng. Pat. 18,048, November 12, 1889. 6d.

CALCINED IRONSTONE mixed with a considerable quantity of clay and the necessary amount of coke is charged into the blast furnace with fluorspar instead of lime. Cast iron containing aluminium is the result. Steel alloyed with aluminium can also be produced "in the blast furnace" by urging a more copious blast of air, whereby the carbon is oxidised and the percentage of it reduced to the necessary amount. It may also be obtained from the cast iron in a cupola or by other means.—A. W.

*Improvements in Rotating Furnaces for Roasting or Calcining Ores or other Substances.* S. Alley, Polmadie. Eng. Pat. 19,533, December 5, 1889. 11d.

THE rotating cylinder is made of iron segments bolted together with flanges, and in the longitudinal joints are fixed long narrow strips of iron projecting into the interior. These strips serve to hold in position the internal lining slabs of firebrick, which are preferably corrugated on the inside surface. The lower end of the inclined cylinder is connected with the fireplace and the receiving chamber, and the upper end is terminated by a smoke-box connected with the chimney, and a feeding apparatus. The ore to be calcined is moved along from a hopper by a rotating paddle into a feed pipe, which passes through the smoke-box a little distance into the cylinder, along which pipe it is conveyed by a revolving helix and thence into the furnace.—A. W.

*Improvements in the Manufacture of Ferro-Aluminium.* C. A. Faure, Paris, France. Eng. Pat. 19,588, December 5, 1889. 4d.

PERCHLORIDE of iron or other vapour rich in chlorine is passed over a mixture of bauxite and carbon heated to redness. The vapours and gases so formed are then led over scrap iron at a red heat, ferro-aluminium and chloride of iron (ferrous chloride) being formed. The latter is condensed and is subjected in a crucible, at a suitable temperature, to a current of air whereby oxide and perchloride of iron are produced. The perchloride of iron volatilises and can be used for a fresh operation.—H. K. T.

*Improvements in and Relating to a Process of and a Furnace for Treating Copper and its Alloys.* W. W. Keys, Bridgeport, U.S.A. Eng. Pat. 11,868, July 29, 1890. 8d.

THE patentee maintains that in order to obtain copper or its alloys of high specific gravity, great strength and minimum susceptibility to corrosion by hot acids, whether cast, rolled, or drawn, it is necessary to purify it and to eliminate the oxides, sub-oxides, and "other gaseous impurities as cause the metal when melted to flow sluggishly." &c. This is accomplished by bringing into contact with the molten metal the products of the incomplete combustion of hydrocarbon oils. Any suitable furnace can be employed, but the specification contains drawings of one in which the bed consists of a kind of shelf and a lower portion called the pot, the whole being heated by liquid or gaseous fuel. The copper is stacked on the shelf, melted and purified by the products of combustion as it trickles down into the pot, whence it is tapped.—A. W.

## XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

*Electrolytic Determination of Nitric Acid.* G. Vortmann. Ber. 23, 2796—2801.

See under XXIII., page 1066.

*Electrolytic Separations.* E. F. Smith and L. K. Frankel. Amer. Chem. J. 12, 428—435.

See under XXIII., page 1067.

## PATENTS.

*Improvements in Electric Batteries.* Sir W. Vavasour, Bart., London. Eng. Pat. 15,230, September 27, 1889. 1s. 8d.

IN this battery one of the cells is sealed hermetically, the electrode passing through the seal. Pressure is developed in the sealed cell during working and tends to force the electrolyte through the pores of the partition into the outer cell, whence it is allowed to flow away at a rate depending upon the output of the battery. The exciting solution is supplied also under pressure to the sealed cell at a suitable rate to make up for the lowering of level by percolation. Several different modes of applying this principle are fully described.—B. T.

*Improvements in Dynamo-Electric Machines for Electro-Plating and like Work.* W. B. Sayers, London. Eng. Pat. 15,700, October 7, 1889. 8d.

TO obtain a low E.M.F. for plating purposes from a dynamo running at a fair speed, the inventor cuts one or more slots in the pole pieces so as to weaken the magnetic field at these points, and puts on intermediate brushes so as to collect currents at one-half, one-third, or any desired fraction of the total dynamo E.M.F.—B. T.

*An Improved Apparatus for obtaining Metals of the Alkalis from Molten Chlorides.* L. Grabau, Hanover, Germany. Eng. Pat. 15,792, October 8, 1889. 8d.

THE difficulty hitherto has been to make the earthenware vessels used in this process last for a reasonable time, and it has been found that their destruction is not due to the heat employed but to the passage of the electric current through the cell; to obviate this the porcelain cell is made of a bell shape provided with a double wall, the top of which rises above the level of the molten chloride so as to

leave a clear gap between the chloride and the molten metal so that the current does not pass through the earthenware, but round underneath into the metal contained in the bell-shaped cell, the metal rising into this cell on account of its lower specific gravity. A delivery pipe leads away from the top of the cell to a receiver containing petroleum in an atmosphere of nitrogen or hydrogen.—B. T.

*Improvements in the Manufacture of Aluminium and other Metals.* D. Dixon, London. Eng. Pat. 16,794, October 21, 1889. 8d.

A MOLTEX halogen salt is decomposed electrolytically in the presence of a mixture of alumina and carbon, one of the elements of decomposition acting on the mixture producing an aluminium compound, which compound is then acted on by the other element of decomposition with the result of metallic aluminium. As an example magnesium chloride is decomposed into its elements, the chlorine reacts with the alumina and carbon at the anode, producing aluminium chloride and carbonic oxide, while the magnesium at the cathode decomposes the chloride so produced, forming magnesium chloride again and metallic aluminium. The process is continuous and can be conducted in one vessel with a porous diaphragm to keep the mixture surrounding the anode separate from the materials near the cathode.

—A. W.

*An Improved Construction of Plates for Secondary or other Voltaic Batteries.* H. T. Cheswright, Carcassonne, France. Eng. Pat. 19,080, November 27, 1889. 6d.

HOLES are punched through a lead plate in such a way as to force some of the metal out on the opposite side, forming a short tube with ragged edges; these holes are punched from each side so that both sides of the plate are roughened, and this roughness serves to retain the active material which is afterwards pasted on the plates. A flange is also cast round the edge of the plate to help to retain the active material.—B. T.

*Improvements in or connected with the Positive Elements (Negative Electrodes in charging) of Secondary Batteries, which Elements are Applicable also as Cathodes in Electrolysis.* The Mining and General Electric Lamp Company, Limited, and D. G. FitzGerald, London. Eng. Pat. 3731, March 8, 1890. 4d.

INSTEAD of using a leaden grid to support the spongy lead of the negative electrode, a grid of copper strip is made up, immersed in melted solder, and afterwards the apertures filled up with "lithanode material," such as a mixture of oxide and sulphate of lead. To effect the formation of the plate it is made the cathode in an electrolyte of magnesium sulphate, sodium sulphate, or potassium or sodium hydrate, or in a solution of dilute sulphuric acid.—B. T.

*Improvements in Primary Batteries and in Switching Apparatus connected therewith.* Sir C. S. Forbes, Bart., London. Eng. Pat. 4246, March 18, 1890. 8d.

FOR convenience of manipulation the cells of this two-fluid battery are placed in a frame mounted on trunnions, so that by tipping the frame the cells can all be emptied at one time. The positive plate is zinc immersed in a solution of calcium chloride or ammonium chloride or sodium chloride, while the carbon is in a solution of hydrochloric acid, sodium bichromate or chromic acid. A divided tank is placed over the cells and contains the two fluids for recharging; a switch is also fixed on each cell for enabling it to be either cut out of or put into circuit from a distance.—B. T.

*Improvements in Secondary Batteries.* M. B. Hollies and J. Warner, London. Eng. Pat. 8086, May 23, 1890. 6d.

A CONTAINING vessel of insulating material or of a conducting material lined with a non-conductor is divided into

liquid-tight compartments by plates of lead, and the compartments are filled with the electrolyte. The dividing plates are used as electrodes, one side of a plate serving as the positive plate and the other side as the negative.

—B. T.

*Improvements in Secondary Batteries.* T. M. Foote, Boston, Mass., U.S.A. Eng. Pat. 10,481, July 1, 1890. 8d.

A LEADEN tube preferably of rectangular section is filled with litharge or minium powder and bent or folded upon itself to form a plate of any desired size, adjacent sides of the tubes being burnt together, and the tubes themselves perforated to give the electrolyte access to the oxides of lead.—B. T.

*An Improved Connector for the Electrodes and Cells of Primary and Secondary Electrical Batteries.* A. J. Jarman, London. Eng. Pat. 10,515, July 7, 1890. 6d.

SCREW threads are cut upon the ends of a bar of suitable metal such as copper, and these ends are then bent round at right angles, and in the same plane, so that the ends are parallel and pointing in the same direction. The bar is then surrounded by a casting of lead leaving the ends projecting, these ends being united by a metallic connector held in position by suitable nuts working on the screwed ends, this connector serving as an additional stay to stiffen the arrangement, and also to lower the electrical resistance. The lead casting is then burnt on to the plates of the battery or attached in any suitable way.

—B. T.

*An Improved Apparatus for Producing Sheets of Metal by Electro-deposition.* M. G. Farmer, Eliot, Maine, U.S.A. Eng. Pat. 11,680, July 25, 1890. 6d.

A LONG cylinder of an alloy of lead and antimony is suspended upon a non-conducting roller and almost entirely immersed in a suitable electrolyte. The cylinder serves as the cathode, and is partially surrounded in the bath by a curved anode of the proper metal. A slightly zigzag line is painted with an insulating varnish on the cylinder parallel to its axis, and this serves to prevent a deposit of metal over the complete surface of the cylinder. Upon the passage of an electric current the cylinder is made to revolve slowly, and a metal sheet of any desired thickness is deposited upon the cylinder, broken only at the line of insulating varnish. This sheet can afterwards be stripped from the cylinder.—B. T.

## XII.—FATS, OILS, AND SOAP MANUFACTURE.

*Addition of Chlorine and of Halogen Acids to Oleic and Elaidic Acid.* S. Piotrowski. Ber. 23, 2531—2533.

OF the halogen addition products of oleic and elaidic acids only those have been previously described which are obtained by the action of bromine. Monochloro- and dichloro-stearic acid and monobromostearic acid are now described by the author.—T. L. B.

*Japan War.* O. Kleinstück. Chem. Zeit. 14, 1303—1304.

See under XXIII., page 1072.

*On the Determination of the Viscosity of Lubricating Oils.* A. Martens. Mitt. Königl. techn. Versuchs. 1890, 143—151.

ENGLER and Künkler, in describing their new apparatus for the determination of viscosity of lubricating oils (see Dingl. Polyt. J. 276, 42—47; this Journal, 1890, 651) make a

critical comparison between this new apparatus and the one used by the author. First, they state it as a disadvantage of the latter apparatus, that it takes a very long time to heat the oil in the air-bath, even if the oil is warm before. Secondly, in cases where the oil is heated outside the air-bath, and then brought into the apparatus, which has to be opened for the purpose, they assert that it is impossible to avoid changes of temperature. Thirdly, it is stated that many experiments show that the use of an undivided air-bath, as employed by the author, does not give uniform temperatures in the space surrounding the viscosimeter, unless the air-bath is of very large dimensions. In reply to these points the author says that to work with a uniform and high temperature throughout is neither required, nor is it a practical method, but that each oil should be tested at 8 to 10 different temperatures from 20° to 150° C., and the results obtained shown in a curve, presenting at a glance the properties of the tested oil. It is necessary only to keep the temperature equal during each single test, and the author has found that the use of an air-bath is the simplest and most convenient way for obtaining this result. The second objection is of no practical importance, but to pour the oil through an aperture instead of opening the apparatus is no doubt an improvement, and the author recommends that this plan should be adopted. It must be added that slight changes in the temperature of the oil do not affect the correctness of the test, if the temperatures are above 100° C., and a mean of the different temperatures observed be taken. The time occupied in pouring the oil into the apparatus is too short to alter its temperature, provided the surrounding air is not considerably colder. Against the third objection, the author gives tables and diagrams, which show that the temperatures in different parts of the air-bath at the same time differ only slightly, and that the curves which are obtained as described above, are quite satisfactory.

All possible errors are too small to be of practical importance, and the author is therefore of opinion that the apparatus, as used by himself, can be perfectly relied upon for all practical purposes, and has the great advantage of being simple in construction.—H. S.

*The Application of the Oleo-Refractometer to the Detection of Adulterations.* F. Jean. Bull. Soc. Chim. [3], 4, 105—108.

See under XXIII., page 1072.

*Lubricating Oils.* A. C. J. Charlier. The Engineer, 1890, 305—306.

AFTER a few preliminary remarks the writer explains that a good lubricating oil must have sufficient body to keep the surfaces between which it flows from coming into contact, hence the reason high gravity oils are now so much used on all classes of machinery; but at the same time everything depends on the class of work on which the oil is to be employed. If for light machinery, a very heavy oil would have a tendency to clog the bearings, thus impeding the speed; therefore for all ordinary machinery an oil ranging in gravity from '850 to '890 should be employed; whilst for heavy machinery, oils ranging from '900 to '980 should be chosen.

An important feature is to obtain oils having the greatest amount of fluidity consistent with body. Many oils are selected because they are apparently of high gravity, but such in reality is not always the case. The commonest paraffin burning oils can now be given an artificial gravity resembling castor oil, and yet immediately they become heated, even to a moderate temperature, they run off the bearings like water. Many of the Russian mineral oils now on the market have a gravity of about '920, are very highly refined and of a splendid colour, and yet when heat is applied they instantly become limpid, and are quite useless for the purpose for which they are required. But still it must be mentioned *en passant* that these Russian oils are very useful in making up compounds with oils not

affected by temperature, as they then supply body to an oil which, although an excellent lubricant, could not be used for heavy machinery on account of its low gravity.

Another point to be considered is to find an oil with a maximum capacity for receiving and distributing heat, together with a freedom from tendency to gum or oxidise; hence none of the drying oils should be used for lubricating purposes, and under this head users of lubricants must be warned against a process, which has lately been discovered, of adulterating lubricating oils with soap, by which is produced a very fine sparkling oil of gravity higher than castor oil, but at the same time utterly useless for lubrication. Users of lubricating oils often lay far too much stress on the colour of the oil, but as many methods are now known for giving oils, good or indifferent, any colour, either ruby, golden, or black, by the addition of the smallest percentage of the many aniline colours soluble in oils, the colour should no longer be taken as a test of quality; all that is required is that the oil should be bright and free from insoluble matter. It is essential that a lubricating oil should be neutral—that is, it should be neither acid nor alkaline. In the refining of many kinds of oil, mineral acids and alkaline earths are used, and, especially in the cheaper oils, sufficient care is seldom exercised in washing them free from all traces of acid; and then, again, it is well known that manufacturers often leave a large portion of alkali in the oils, as this greatly helps to make up their gravity.

The following are the more ready tests for the practical man:—With regard to the gravity, the oil is placed in a cylindrical glass vessel, and tested by the hydrometer. This method is very useful, because the gravity of the oil can be determined at any temperature. The glass vessel can be heated in a water-bath, and the gravity taken by placing the hydrometer in the oil at any moment. By this means it can be seen if the sample retains its original gravity when heated.

The "flashing point" of an oil is understood to mean the temperature at which the escaping vapour will momentarily ignite. The standard animal and vegetable lubricating oils, and all mineral oils of good body and high gravity, decompose or vaporise only at temperatures exceeding that of steam in ordinary engines, but nevertheless many of the lubricating oils now in the market are so worthless that it is very essential to know a ready means of ascertaining their flashing point. There are many good forms of testers, such as Abel's, Bernstein's, or Bailey's, but as they require very careful manipulation, the author suggests a simple apparatus, which can be worked very easily, and at the same time gives fairly accurate results. A small glass beaker is fitted into a larger one by means of a cork or india-rubber band; the former is to contain the oil, the latter serves as a water-bath. The smaller beaker is closed at the top by means of a cork, through which is inserted a thermometer dipping well into the oil, and a small piece of glass tubing tapering to a point, through which the vapour ascends. The oil should be on an exact level with the water in the outer vessel, so that the same pressure exists in both vessels; and when an oil to be tested is supposed to have a flashing point above that of boiling water, an oil-bath should be used in place of water. Everything being ready, the apparatus is stood on a sand-bath, under which is placed a spirit lamp, and gradually heated. A lighted taper is applied continually to the aperture through which the vapour from the oil is ascending, and immediately a small blue flame appears the temperature is noted, and the flashing point of the oil under examination thus determined. Any oil having a flashing point below 300° F. should be at once discarded as useless.

Another very important test is that for the viscosity or fluidity of an oil, and here a very simple and general test is to dip blotting paper in the oil and hold it up to drain; symmetrical drops indicate good fluidity, a spreading tendency viscosity. Again, an ordinary glass tube having a diameter of half an inch, tapering to a point at one end, and marked into divisions of 1 in., will answer all ordinary purposes for testing the viscosity of an oil. The oil to be tested is placed in this tube up to a given mark, and is then allowed to run out at the tapered end of the tube, and the time

taken is noted. This is compared with the time taken by standard oils previously ascertained in the same tube, and thus the viscosity of the oil can be determined. Sometimes it is necessary to take the viscosity at different temperatures, and in this case the glass tube can be fitted into an outer jacket containing water heated up to the required temperature. For all light machinery running at high speed, low gravity oils having a low fluidity should be looked for, whilst for heavy machinery of all kinds high gravity oils, with a moderate fluidity, should be employed.

An oil evaporating more than 5 per cent. in 12 hours, at a temperature of 140° F. is useless, as the evaporation creates a viscous residue, or leaves the bearings dry. To test for this, a weighed quantity of the oil should be placed in a porcelain dish and heated for the requisite time, then cooled and weighed and subtracted from the original quantity; the difference in weights constitutes the loss by evaporation.

The best lubricating oil is that which has the greatest adhesion to metallic surfaces, and the least cohesion in its own particles, and bearing this in mind there is no doubt but that mineral oils come first, sperm oil second, neat-foot oil third, and lard oil fourth; hence the finest mineral oils are best for light bearings and high velocities, and to give body to mineral oils fine sperm oil is used, or when greater tenacity is required, lard and neat-foot oils may replace sperm oil, while for the heaviest machinery mineral oils alone cannot be recommended, being deficient in body and of relatively low flashing point.

At the present time it is not so much a matter of quality which troubles the engineer; it is the question of cost. Lubricants answering in every way what is required of them can be obtained, but their cost is far too high for the ordinary consumer, and it therefore necessitates producers to search for compounds which will give to cheap oils the same properties as sperm, lard, &c., and be able to sell them at about half the price.

Mineral oils are the cheapest lubricants known, and yet they are often discarded for one reason, because they do not possess the same body as many of the vegetable and animal oils, and hence require a larger quantity to be used to do the same work. But though double the quantity of mineral oil is required to do the work done by other oils, yet as the price of the former is only one-quarter that of the latter, the mineral oils are still by far the most profitable to be used.

Oleate or stearate of alumina is now greatly used for giving a body to light gravity mineral oils. It is a very cheap compound, and can be added at a very small cost. The production of this "metal soap," as it is called, is well worthy of consideration, and can be well classed as a very successful result of research work recently done by several chemists in endeavouring to produce cheap lubricants. The high-class animal and vegetable oils in such high favour amongst engineers for their lubricating powers consist principally of olein and stearin, and these two substances, which give to these oils their high lubricating powers, can now be introduced into cheap mineral oils, thereby converting them into the finest lubricants at a cost far below that paid for castor, sperm and such like oils. The oleic and stearic acid is obtained in the usual way from any of the oils rich in olein and stearin, and is then precipitated with alum in the presence of caustic soda, thus forming oleate and stearate of alumina. A very small percentage of this metal soap dissolved with warming in light gravity mineral oils will increase their gravity some "50° or 60°," will greatly improve their lubricating properties, and after filtering through fine copper gauze, will give them a brilliancy not surpassed by any of the finest animal oils in the market, and at the same time not increase their cost of production more than 20s. per ton.

Some manufacturers use now a process of thickening their oils with ordinary soft soap, but this adulteration can be easily detected by adding glacial acetic acid and warming, when the soap will at once separate out. The writer recently examined a very fine-looking sample of lubricating oil, resembling in appearance castor oil, and found on estimation that as much as 60 per cent. of soap had been

introduced into the oil. Any oil found to contain such soap should be at once rejected.

Lardine and blown rape oil are now also largely used for giving body to lubricating oils. The former consists principally of cotton oil, which has been heated in the presence of a strong blast of air, somewhat similar to the process employed for thickening linseed oil, whilst the latter consists principally of colza oil treated in a similar manner. The presence of these "thickeners," as they are termed in the trade, cannot be said to visibly deteriorate the lubricating powers of the oil with which they are mixed, but they certainly do not improve it, and unfortunately they quickly become dull and cloudy, and in order to prevent this rosin oil must be used in conjunction with them. A small percentage of, say 1 per cent. of rosin oil, does not deteriorate the lubricating properties of an oil; but one containing above this percentage cannot be recommended for lubricating purposes. The presence of rosin oil can be detected in mineral oils by treating a small portion of the sample with an alcoholic solution of caustic soda, heating on a water-bath, evaporating nearly to dryness, adding a large quantity of distilled water, and boiling for some time, when a milky liquid will be formed; on the addition of more water and warming, the oil which separates, if free from rosin oil, should be clear, while a brown colour would denote the presence of rosin oil. As a confirmatory test, the aqueous liquid is drawn off from beneath and acidified with sulphuric acid; if no precipitate, the oil was all mineral, as a precipitate collecting, on warming, in brown viscous drops confirms the presence of rosin oil. But if instead of a milky liquid a semi-frosty mass is obtained after having added the distilled water to the evaporated solution, a fatty oil is evidently also present with the mineral and rosin oil; on adding more water the mineral oil will float to the top if present. The lower layer is then shaken up with amyl alcohol; when the alcohol separates as a brown layer, rosin oil is present. On further treatment of the aqueous solution with acid and warming, a separation of oleic acid, with its characteristic odour of fat, will show the presence of a fatty oil, either lard, neat-foot, or cotton oil.

For the lubrication of bearings of the largest size on which, either from the weight of the shaft or fly wheel, or from the drag of belts or ropes or from the formation of the bearing, very great pressure per square inch has to be resisted, castor oil up to the present appears to have no equal; and, in order to keep such bearings cool, it is very essential that this oil should not be adulterated. The adulterants to be looked for in castor oil are principally lard and colza oils, and they can be at once recognised by the density. The specific gravity of castor oil is .960; lard oil, .916; rape oil, .912; therefore, if the gravity is below .955, this alone indicates the presence of one of these oils. Again, another very characteristic test of castor oil is by the addition of zinc chloride. When pure it becomes yellow; when lard oil is present it becomes milky, and if colza be present a green colouration will be obtained.

Again, sperm oil is still very largely used by the leading cotton spinners, and the reason for this is that it leaves no stain and does not thicken by age or friction. Here again, on account of the high price of this oil, it is often adulterated, and generally with seal oil, cotton oil and mineral oils. These adulterants can also be easily detected with zinc chloride; if pure sperm oil a milky solution will be obtained, and if adulterated with any of the above-mentioned oils a brown colouration will be obtained.

Regarding the claims of tallow as a lubricant, there is no doubt but that, while in every case hydrocarbon oils are safer, and in the majority of cases are better and cheaper lubricants than tallow, even of the best quality, there is a number of cases in which engineers, although fully alive to the trouble and danger which are inseparably connected with the use of tallow, are constrained to use it, having failed to find any sufficient substitute. The great fault with tallow is that it corrodes metal, and often leaves a kind of deposit; and, again, it almost always contains free acids, as much as 25 per cent. of free fatty acid having been found in a sample of town tallow. Large proportions of free acid are apt to be due to the tallow being adulterated with wool-grease acids, or stearic acid from cotton-seed oil. Tallow,

again, frequently contains more or less water, infusible matters, and mineral impurities, and has been often purposely adulterated with starch, china clay, whiting, &c. For the detection of these mineral impurities, a small sample of the tallow should be dissolved in petroleum spirit, filtered, the residue washed with a little ether, and dried at a moderate temperature. On boiling the residue in water and adding iodine, a blue colouration will indicate the presence of starch; while effervescence of the residue on the addition of hydrochloric acid proves the presence of whiting.

**Report on Fired Oils.** Report of the Central Laboratory of the Italian Customs Department, 1886—1889, 65—83.

**FIXED** oils are divided in the tariff into two categories, viz., vegetable and animal oils. Of the former class fixed oils not specified are subject to a duty of 15 lire per quintal, exception being made of pure olive oil which pays 6 lire, cotton oil 15 lire, in addition to a surcharge of 14 lire, while palm and cocoa-nut oils, as also various kinds of oil which serve for medicinal preparations, are free of duty. Mixtures of olive oil with cotton-seed oil and other seeds are taxed as seed oils. Of the second class or animal oils, those of fish, when pure, are classified as medical substances not specified, if impure under No. 6, letter *b* of the general tariff; if not of fish, such as neatsfoot oil, they are assessed as fats of all sorts.

**Olive Oil.**—To ascertain the adulterations present in olive oil there are determined (i.) the specific gravity by means of the areometer of Pinchon which affords sufficiently accurate results according to the experiments of Del Torre (Conclusioni della Commissione Scientifica per gli olii, 1887) provided that a heavier oil has not been added to counterbalance the addition of a light oil; (ii.) the degree of hardness of the solidified oil by the apparatus designed by Serra-Carpi (*supra*); (iii.) the fusing point of the free fatty acids by the following method: the fatty acids, separated in the usual manner, are aspirated into a small bulb, which is bent round, then attached by wire to a thermometer, and the whole immersed in water. The temperatures both of fusion and of solidification are noted. A remark is made that the statements of Bach (*Chem. Zeit.* 7, 356) regarding these points are not sufficiently exact, and therefore they cannot be regarded as absolute criteria of the purity of the oil; (iv.) refractive index and dispersive power. A series of determinations have been made of these constants for various oils, values for some of which are given in the following table:—

	Refractive Index at 20°.	Dispersive Power referred to rays F and G.
Olive oil from various sources	1.4629 to 1.4637	*03914 to *04
Cotton oil.....	1.4667	*0387
Colza.....	1.4665	*0398
Sesame.....	1.4658	*0386
Earth-nut.....	1.4645	*03889

It is stated that these values approximate so closely to one another that they are not available for the detection of adulteration; (v.) the iodine number conducted according to the process of Hübl; it is considered that the value may vary between the extreme limits of 80—85, but more generally only from 80—83; (vi.) the saponification number or the quantity of potash expressed in milligrammes required to saponify 1 gm. of the oil (Köttstorfer, *Zeits. Anal. Chem.* 18, 199). The following values are given for various oils:—

Olive.....	191 —196
Poppy.....	192.8—194.6
Almond.....	187.9—195.4
Colza.....	177 —178.7
Sesame.....	190
Earth-nut.....	191.3—196.6
Cotton seed.....	191 —196.5

This determination is especially useful for mixtures of olive and colza oils; (vii.) Maumene's reaction on the rise of temperature produced by mixing 55 cc. of the oil with 10 cc. sulphuric acid of 66° B. Various samples of olive oil of undoubted purity produced a rise of 38° to 44.7°; for other oils Del Torre gives the following mean values:—

Cotton seed.....	69—70
Sesame.....	65
Flax.....	109
Earth-nut.....	58
Colza.....	59

In the opinion of the Direction, Maumene's reaction gives excellent results, provided that the operation is always conducted in the same manner, and very concentrated acid is used.

For the detection of various seed oils in mixtures, there are employed (1) the reaction of Hanchecorne, pointing out that the red colour produced in samples of rancid oil is easily distinguished from that produced by seed oils, a statement in opposition to the criticisms of Bizio (*R. Istituto Veneto*, 1885). (ii.) The reaction of Buillé, which is considered to afford a good proof of the addition of extraneous oils, provided that the minute precautions laid down by the author are exactly followed. (iii.) The reaction of Bechi for cotton-seed oil, which consists in adding to 10 cc. of the oil to be examined 1 cc. of the silver nitrate solution and 10 cc. of pure colza oil in amyl alcohol; the mixture is divided into two portions, of which one is warmed to 100° when a black colouration is produced if cotton-seed oil is present. The following prescriptions were laid down by the Scientific Commission: for the solutions, silver nitrate, 1 gm.; ethyl alcohol at 98 per cent., 200 cc.; ether, 40 cc.; and nitric acid, 0.1 gm.; and for the other, amyl alcohol, 100 cc.; pure colza oil, 15 cc. It is pointed out that excellent results are obtained, though in certain cases olive oil from Asia Minor and Corfu, made from fermented olives and kept for some time in stables, whereby ammonia was absorbed, gave the reaction of Bechi. Special tests are also quoted for the oils of colza, sesame, and earth-nut. The samples sent to the laboratory were found for the most part to agree with the stated declarations.

**Fish Oils** are classified in the tariff as impure fish oil, which includes the oils of porpoise, whale, and dog-fish, or as medicinal preparations, various rectified oils, and cod-liver oil. By a decree March 31st, 1890, the duties on impurities and adulterations of pure fish oil shall be determined by the Minister of Finance.

The work of Schädlér on the fish oils is alluded to (Benedikt *Analyse der Fette*, 236) and adopted by the Department. To recognise cod-liver oil a qualitative examination is made to detect the presence of the contained iodine; the method consists in saponifying the oil with caustic potash, evaporating the soap solution, and calcining the residue, in which the iodine is found in the usual manner. Samples declared as impure fish oil were recognised as pure fish oil, and in one case a sample of pure cod-liver oil was imported as a heavy mineral oil.—V. H. V.

## PATENTS.

**Improved Apparatus for and Method of Extracting Oleaginous and other Added Matters from Fibrous, Spun, Textile, and other analogous Substances.** E. Mansfield, London. Eng. Pat. 14,364, September 12, 1889. 8d.

See under V., page 1033.

**Improvements in Treating Crude Cotton-Seed Oil and Oils containing Resinous Matter and Free Fatty Acids to obtain Oil, Soap, and Resinous Colouring Matter.** R. Hunt, Liverpool. Eng. Pat. 17,870, November 9, 1889. 4d.

The oil to be treated is intimately mixed with water in the proportion of 2:1, by running both liquids in two streams into a rapidly revolving basin, where they are forced through a narrow slit and projected in thin films

against the surface of an outer vessel. The mixture, which now forms an emulsion, is allowed to stand for some hours, so that part of the water may be removed. To the supernatant emulsion half to  $1\frac{1}{2}$  per cent. of caustic soda and about 1 per cent. of common salt are added and the whole is thoroughly agitated and heated to  $110^{\circ}$  to  $160^{\circ}$  F. After settling, the liquor is treated with one-third to one-half its bulk of caustic soda solution of 4—5 Tw. containing one-half to 1 per cent. common salt at a temperature of at first  $110^{\circ}$ — $120^{\circ}$  F., then  $130^{\circ}$ — $160^{\circ}$  F. From the precipitate which settles out after both treatments with caustic soda the soap may be separated mechanically, the residue containing the resinous colouring matter.—K. E. M.

*Improvements in the Oxidation and Thickening of Oils for Use in the Manufacture of Paints, Varnishes, Linoleum, Floorcloth, or for other purposes to which Thickened or Oxidised Oils are applicable.* L. T. Thorne and "Brins Oxygen Company, Limited," London. Eng. Pat. 18,628, November 21, 1889. 8d.

Oils are oxidised for the purpose of bleaching or thickening in steam-jacketed vessels, by subjecting them to the action of pure or nearly pure oxygen in a finely divided state. Without the use of driers the process occupies two to seven hours; the presence of a very small quantity of driers shortens the time of oxidation. Consumption of oxygen per ton of oil varies from about 2,000 c. ft. to 4,000 c. ft. according to the degree of oxidation required. (See also Eng. Pat. 12,652 of 1886; this Journal, 1887, 443.)

—K. E. M.

*Improved Process for the Separation of an Extract called "Lanoresin," or Gum Resin, from the Waste Waters from Wool Washing and Combing Mills, and for the Production of the same in a Pure Condition.* C. Lahusen and C. Feiertlin, Delmenhorst, Germany. Eng. Pat. 18,642, November 21, 1889. 6d.

"LANORESIN" is a dark-coloured resin obtainable from the waste liquors of wool-washing mills. It is insoluble in benzene, ether, chloroform, carbon bisulphide, acetone, or strong alcohol, but is dissolved by water and dilute alcohol. To obtain it, the precipitate formed on the addition of a mineral acid to the waste liquor is soaped and mixed with 3—5 times its volume of benzene, heated and thoroughly agitated. During the agitation alcohol of about 95 per cent. is added to the amount of one-tenth the benzene; after standing some time the mixture separates into two layers, the lower one containing the "lanoresin." This is again treated in a similar manner to remove traces of grease, and finally the solvent distilled off.—F. H. L.

*An Improved Process of Filtering Oil.* C. Baker and W. E. Crane, Minneapolis, U.S.A. Eng. Pat. 4607, March 25, 1890. 8d.

THE improvement consists in passing the waste oil from bearings, &c., through a suitable vessel containing a porous filtering medium entirely submerged in a liquid of greater specific gravity than the oil. The oil by contact with the liquid becomes thin, so that in passing through the filtering material the substances held in suspension are more easily separated. The filtering material not being exposed to the atmosphere does not gum or clog up.—K. E. M.

*An Improved Filter for Oil and other Liquids.* C. A. Koelher, Neumühlen, Germany. Eng. Pat. 7229, May 9, 1890. 6d.

THE filter is so constructed that the liquid to be filtered passes through the filtering medium contained between perforated vertical plates which are movable so that the porosity of the filtering material may be increased or decreased by loosening or compressing it.—K. E. M.

### XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

*The Origin of Gutta-Percha.* Sérullas. Compt. Rend. 111, 423—426.

THE discovery of gutta-percha was announced by W. Montgomerie in 1842, and the first samples brought to London in 1843 by José d'Almeida. Hancock and Wheatstone recognised its potential usefulness, but Walker was the first to apply it to submarine telegraphy in 1849. Substitutes have been sought for it without success, and attempts to utilize the exudations of other trees than those of the genus *Isonandra* have also failed, though adulteration by such means is not unknown. Reckless destruction of the original forests and failure to replace the trees when exhausted have decreased the available supply and make the prospects of future cables by no means satisfactory. The tree first recognised as a source of gutta-percha is the *Isonandra gutta* of Hooker; it has been regarded as extinct in Singapore, but is as a matter of fact only extremely rare. As recently as 1887, it flourished in the forest of Boukett Timah (Tin Hill) in the interior of Singapore, where it was originally discovered in 1847 by Lobb, who brought specimens to the collection at Kew. It is still found in other portions of the Malay peninsula. A detailed botanical description is given in the *London Journal of Botany*, 6, 463, under the head of *Isonandra gutta*. The author describes it when at maturity (30 years): the height of the cylindrical stem is 13—14 m. and its circumference about 0.9 m.; its leaves are 11—13 cm. long by 4—6 cm. broad in the case of the fully grown tree, but larger when it is young. The length of the petiole is 1.75—3.75 cm., the flowers 13—14 mm., and their peduncle 6.7 cm.; the fruit is about 3—4 cm. by 2.5—3.5 cm.; the seed about 1.8 × 1.2 cm.

There are at most five other trees which may be mistaken for the true *Isonandra gutta*, and the quality of their product at once differentiates them from it.

It is noteworthy that the word *gutta* (*guetate* or *guetutta*) simply means gum or bird-lime, so that the French term *gomme gutte* is a pleonasm. *Percha* (*pertcha* or *perfia*) is not, as has been supposed identical, with *perca* (i.e., the native name for Sumatra, meaning the world or habitable globe); but signifies *rag* or *fragment of stuff*, the term having reference to the appearance of the product after treatment with warm water.—B. B.

*Report on Compounds of Lead.* Report of the Central Laboratory of the Italian Customs Department, 1886—1889, 341—342.

AMONG substances sent to the laboratory were samples of lead acetate, specially mentioned in the tariff report, of a mixture of zinc oxide and sulphide with barium sulphate, declared as zinc oxide, but the laboratory decided that it should be classed as an adulterated white lead; and, lastly, of mixtures of barium sulphate and lead carbonate, which the tariff distinctly states are to be taxed as white lead.

—V. H. V.

*Report on Varnishes.* Report of the Central Laboratory of the Italian Customs Department, 1886—1889, 379—381.

VARNISHES are classified in the report under two different headings, viz., varnishes containing spirit which pay 30 lire per quintal, and in addition the surcharge on alcohol, and varnishes of every other kind which pay 20 lire per quintal. These varnishes are distinguished from oil of flax and siccativ resins, which are assessed as fixed oils not specified.

In cases of dispute the Department determines the alcohol and other volatile liquids, such as turpentine, benzene, carbon bisulphide, by processes of extraction and distillation, as also the nature of the residue. Among samples sent was one declared as a chemical product not specified, but recognised as a varnish containing turpentine, oil of flax, and lead oxide, while another declared as aluminium sulphate was a varnish of similar nature.—V. H. V.

*Cinnabar and Vermilion in China.* Board of Trade J. November 1890, 577.

THERE are cinnabar mines in the western and northern provinces of China. The pure metal is obtained in Ho-Nan and Kwei-Chow, and is brought to market in stone jars or enclosed in the joints of bamboo. It is also, says the United States Consul-General at Shanghai, manufactured from quicksilver by the reaction of sulphur and saltpetre on the metal in small copper furnaces, in which it is collected, after sublimation, in acicular crystals. Cinnabar is used in colouring red lacquered ware. It is also employed in painting, and forms an ingredient in many medicinal preparations. In former times it was highly prized for its virtues, and regarded as the true philosopher's stone and the immortal elixir.

Vermilion is made of fine cinnabar, which has been purified by sublimation, and is collected in acicular crystals of a bright violet red. It is powdered between two stones turned by hand, mixing a little water at the time. The sticky mass is then put into pure water, decanted, and finally dried on heated tiles or in the sun, when it is sifted for packing. The workmen are particular about the purity of the water used. It is used for making Chinese red ink, for painting on porcelain and wood, and colouring candles and paper. Its consumption is enormous. The most of the numerous temples throughout China are painted red, and everything lucky and pleasant among the Chinese is of vermilion colour. It is made by mixing together two parts of red sulphur and one part of mercury and sublimating the mixture. Fukein vermilion is said to be the best. Han-Kow supplies an inferior quality.

#### PATENTS.

*Improvements in the Treatment of India-Rubber for the Purpose of Dissolving it or rendering it Soluble.* S. Kenyon, Warrington. Eng. Pat. 14,150, September 7, 1889. 4d.

Two parts of old rubber, finely divided, are heated with one part of a "distillate or foots produced in the manufacture of varnish from gums or gum resins" in a still to a temperature of 120°–150° C. for about 12 hours. During the operation the sulphur volatilises, and the product becomes soluble in carbon bisulphide.—F. H. L.

*Improvements in the Treatment of Textiles by Means of Ammoniac Copper for the Purpose of making them Waterproof and Uninflamable.* C. Baswitz, Berlin, Germany. Eng. Pat. 16,708, October 22, 1889. 6d.

As is well known, cuprammonium affects and ultimately dissolves the cellulose of vegetable textile fibres. It is commercially prepared and applied by the patentee in the following way:—To a solution of copper sulphate, soda lye is added, but not to alkaline reaction, and the precipitate thus obtained collected on a filter and washed. It is then dissolved in ammonia solution of 0.91 specific gravity in the proportion of 1,000 cc. of ammonia solution to 150 grms. of copper sulphate. The textiles to be treated are by means of rollers passed through a vessel containing this solution, whereby their surface becomes parchment-like. Then the ammonia is removed from the textiles in a drying chamber, and the material afterwards passed through a hot solution of aluminium acetate, by which treatment basic aluminium acetate is formed, the waterproof property of which is well known. If a security against inflammability be desired, the aluminium acetate solution may be mixed with aluminium sulphate solution in the proportion of 10:1. At the same time basic ammonium aluminate is formed, which adheres fast to the fibres.—H. S.

*Improvements in Resistant Coverings for Battery-Room Floors or Surfaces, Laboratory Floors, and like uses.* R. E. B. Crompton and B. H. Jenkinson, London. Eng. Pat. 17,623, November 5, 1889. 4d.

See under IX., page 1038.

*Improved Means and Process for Treating Iron and other Metals, and the Production of a Fireproof Coating thereon preparatory to Ornamenting with Fusible Colours.* J. Meese, Leer, Prussia. Eng. Pat. 17,878, November 9, 1889. 4d.

FINELY powdered oxide of nickel is mixed with a small percentage of chromate of iron, lead glass flux is then added and the whole triturated with "stearic oil" and turpentine. The articles are coated with this mixture and "fired" in a muffle. A coating, valuable on account of its light shade and dull appearance, is thus obtained upon which fusible colours or metals in the form of powder can be applied and burnt in.—S. G. R.

*Improvements in the Manufacture of Floor Oil-Cloth and like Painted Fabrics, and Apparatus therefor.* F. E. Warburg, London. From C. van Nueffel, Antwerp, Belgium. Eng. Pat. 18,915, November 25, 1889. 8d.

This invention economises time, simplifies the machinery, and prevents loss in the manufacture of floor cloth, American cloth, table covers, and similar fabrics, by supplanting the different processes and manipulations of shearing, pumicing, coating, and drying by a combination of apparatus which allows a length of fabric sufficient to completely fill a drying chamber to be finished without handling. For detailed information the drawings accompanying the specification must be consulted.—K. E. M.

*An Improved Cement used for Covering Boilers, Steam Pipes, or Vessels containing Steam or Heated Water.* W. H. Lonsdale, Blackburn. Eng. Pat. 19,906, December 11, 1889. 4d.

See under I., page 1024.

*A Furniture Polish and Reviver of Leather and the like.* W. W. Box, Crayford. Eng. Pat. 20,438, December 19, 1889. 4d.

This polish consists of equal parts of linseed oil, vinegar, and methylated spirit, with a small quantity of butter of antimony. Colouring matter may be added if desired.

—F. H. L.

*Improvements in the Process of Manufacturing Thin Sheets of Nitro-Cellulose.* E. N. Todd, Newark, New Jersey, U.S.A. Eng. Pat. 9315, June 16, 1890. 8d.

See under XIX., page 1060.

*The Manufacture of New Material designed to serve as a Substitute for Bone or Celluloid.* W. M. C. Callender, London. Eng. Pat. 12,375, August 7, 1890. 4d.

THE new material termed "lactite," is produced by reducing casein to a gelatinous condition by means of borax, ammonia, &c., and then mixing it with a mineral acid and water. The following procedure gives good results:—10 kilos. of casein are placed in a vessel and 3 kilos. of borax dissolved in 6 kilos. of water are incorporated with it and heated. The water is then run off and to the gelatinous casein 1 kilo. of acetate of lead dissolved in 3 kilos. of acetic acid is added and the mass thoroughly worked together in a mechanical mixer. The acid water is then drawn off and the solid matter subjected to great pressure to drive out all possible moisture. The last traces of moisture should be driven out by the aid of heat, the resulting product being the new material. The new material may be supplied in the form of sheets, &c., and may be coloured by suitable pigments or dyes.—B. H.

## XIV.—TANNING, LEATHER, GLUE, AND SIZE.

### PATENTS.

*Processes for Preserving and Removing or Recovering the Colouring Matters from Tanning and other Vegetable Extracts.* B. Nicholson, South Norwood, and T. Palmer, London. Eng. Pat. 15,450, October 1, 1889. 6d.

For preserving the extract, the means described in Eng. Pat. 15,766 of 1887 (this Journal, 1888, 779) are used. The following method has been found effectual for the removal of the colouring matter from hemlock-bark extract. To the liquor, "at a density of about 40° Barmetre," is added about 1 per cent. by weight of powdered "Cayota" bark and 0.25 grms. mercuric iodide (dissolved in a suitable solvent) to each 1,000 grms. of the liquor. It is preferable to add also 2 per cent. of turpentine, either crude or specially oxidised. In place of "cayota" or in conjunction with it and turpentine, certain bodies, such as "sea-water, milk, egg albumen, blood serum, solution of borax, and the like, also herring brine, and some of the amides which possess an affinity for the camphoraceous and other substances produced during the oxidation of the turpentine" may be used. The liquor is run into oxidising vessels, and a current of air, warmed to a temperature of 100° F. is forced through it for a period of from 20 to 30 hours. Means may be employed to collect the volatilised products. The liquor is then diluted with water, warmed to 180° F., and filtered. The oil of turpentine may be recovered by mixing the liquor with "ether, light turpentine, light petroleum, benzoline, or the like," and separating the liquor from the ethereal solution.

The above process is not suited to the extracts from certain materials, such as chestnut. In the case of these barks the liquor is violently agitated in the cold with petroleum ether, run into a separator, and after standing, the liquor run off from the ethereal solution.—B. H.

*Process and Apparatus for Glazing Leather.* H. Bogenschield and F. Basch, Berlin, Germany. Eng. Pat. 16,595, October 21, 1889. 6d.

This invention is "to improve the glazing or glossing of leather by means of an apparatus in which the glazing cylinder not only moves to and fro, but also has a turning, pendulous or tilting motion given it, owing to which the cylinder presses the leather with greater energy, at the same time sliding, with the alteration in the direction of force, over the leather." Details are given in the specification.

—B. H.

*New or Improved Flexible Material applicable as a Substitute for Wood or Leather, and Process of making the same.* W. P. Thompson, Liverpool. From C. Heepe, Boekenheim, Germany. Eng. Pat. 18,730, November 22, 1889. 8d.

The material consists of wood plates or veneers and a tough and elastic foundation material or core.

The material is manufactured in the following manner:—The core or foundation (hemp, &c.) is laid on a veneer or sheet of wood in such a way that the single threads stand apart at least 6 to 8 mm. A thin layer of glue (containing glycerin or similar substance to prevent the glue becoming brittle) is then put on, and another veneer laid on. The whole is placed in a press, both pressure surfaces of which are coated with a sheet of india-rubber, or the like, and the pressing continued until the shape of the core or foundation is shown on the outer surfaces of the wood, whereby it is judged that the two surfaces of wood have come into complete contact. A characteristic of the invention is the employment of a wide meshed net between the veneers as a core, so that contact of the surfaces takes place between the meshes of the net. Instead of wood, pasteboard may be employed. A drawing is given.—B. H.

## XV.—AGRICULTURE, MANURES, Etc.

*Commercial Fertilisers.* Kentucky Agricultural Experiment Station Bulletin, 29, 1890.

This bulletin is explanatory of the constitution and uses of common commercial fertilisers, and is issued for the instruction of the Kentucky farmer; it therefore contains little that is not well known to agricultural chemists. The following may be noted as bearing upon points which are, perhaps, debatable or new.

Steamed or desiccated bones, if not very strongly steamed, are better for fertilisers than raw bones, and this, notwithstanding that the steaming removes some of the nitrogen. The fat of the raw bones adds weight, clogs the meal, and hinders the decomposition of the bone in the soil.

After standing, or when applied to the soil, the phosphoric acid of superphosphate has reverted to a form insoluble in water. This reverting of the phosphoric acid does not materially change its value as a fertiliser, for experiments (not here quoted) have shown that plants can take up the phosphoric acid in this state as readily as in the soluble form. The term "available phosphate" is sometimes employed to include both "soluble" and "reverted" phosphates.

An acre of wheat, yielding 20 bushels, requires about 28 lb. of potash ( $K_2O$ ?); an average crop of potatoes requires 100 lb. of potash per acre, and an acre of tobacco, yielding 3,800 lb. of leaves and stalks, assimilates over 200 lb. of potash.

Fertilisers are generally best sown broad-cast or drilled. When a small quantity of fertiliser is applied to each hill or row at planting time, it acts mainly as a stimulant to produce an early and vigorous start, which is considered necessary for the tobacco crop, but often renders the crop more sensitive to drought. In any case care should be taken to mix the fertiliser with the soil, so that it shall not come in contact with the seeds or plants. Most fertilisers, and especially those containing much nitrogen, soluble phosphoric acid, or potash, will injure or destroy young plants if brought in contact with them.

The following values per pound are ascribed at this station to the essential ingredients of fertilisers:—Phosphoric acid, soluble in water, 8½ cents; "reverted" phosphoric acid, 8½ cents; insoluble phosphoric acid, 3 cents; phosphoric acid in fine bone (capable of passing through a sieve with meshes one-twenty-fifth sq. in.), 4½ cents; phosphoric acid in medium bone (passing through meshes one-sixth sq. in., but not including fine bone) 4 cents; potash from potassium chloride, 5½ cents; potash from potassium sulphate, 7 cents; nitrogen, 20 cents.

Tables showing the analyses of various fertilisers now in the American market are appended to the bulletin.

—A. G. B.

*International Congress for Agriculture and Forestry, held in Vienna from September 2—6, 1890.* Chem. Zeit. 14, 1246—1247.

In the section of the Congress for agricultural investigations, the methods at present in use for the analysis and valuation of artificial manures received special attention. The following points were discussed:—

*Bone Meals.*—J. Stoklasa recommended the determination of the fat, the degree of fineness, and the character of the nitrogenous substance.

*Thomas Phosphate Powder.*—Stoklasa considers that the phosphoric acid rendered soluble by treatment with 20 per cent. citric acid should be considered the available phosphoric acid.

*Superphosphates.*—N. von Lorenz recommended the "citrate" method as used at Halle. The ammonium citrate solution is prepared by dissolving 1,500 grms. of citric acid in water, to which is added 5,000 cc. of 24 per cent. ammonia, the whole being then diluted to 15 litres. 50 cc. of a solution of the superphosphate (= 1 gm. of substance) are treated with 50 cc. of the ammonium

citrate; 25 cc. of magnesia mixture are immediately added, and the whole well shaken during half an hour. In the case of concentrated or "double" superphosphates, one-half the amount of the solution is taken (= 0.5 gm.) diluted with 50—75 cc. of water, heated on the sand-bath for one hour with 10 cc. of fuming nitric acid, and then neutralised with ammonia, again slightly acidified with nitric acid, and finally treated with 50 cc. of citrate of ammonia and 25 cc. of magnesia mixture as above described.

*Nitrogen in various manures.*—For the determination of nitric nitrogen, both Jodlbauer's modification of Kjeldahl's method and also Schloesing's were recommended by A. Devarda.

In the section for agricultural industries the question was discussed as to what extent saccharine has replaced sugar, more especially beetroot sugar, in commerce, with the result that the evidence indicated that saccharine was not displacing sugar in the markets, although it appears to be without any dangerous or even unpleasant consequences on the human being. During the last four years, 40,000 kilos. of saccharine have been manufactured.—J. W. L.

*The Composition of Vegetable Cell-Membranes.* E. Schulze. Ber. 23, 2579—2583.

See under XVI., page 1051.

## XVI.—SUGAR, STARCH, GUM, Etc.

*Invertase: A Contribution to the History of an Enzyme or Unorganised Ferment.* C. O'Sullivan and F. W. Tompson. J. Chem. Soc. 1890, 834—931.

BEFORE the publication of this paper, little was known concerning the nature and properties of unorganised ferments, and that little was of a very conflicting nature, the statements of various observers differing considerably. The objects which the authors had before them in the pursuit of their work were: to throw some light on the mode of action of these ferments, *i.e.*, to determine whether it was a life action, or, in general, whether it differed in any way from a simple chemical action; and to determine if they had a constant composition, and, if so, their chemical constitution. The authors chose invertase for the purpose of the investigation because its special property, the inversion of cane sugar in the cold and at moderate temperatures, is a very simple action and one which can be easily followed by polarimetric observations; also because they succeeded in discovering a method by which it may be prepared in quantity.

In order to devise a method for determining invertase, it is necessary to first obtain a knowledge of its properties.

Invertase is the only known body which has the property of inverting cane sugar solution in the cold and at moderate temperatures; and this property is the only known distinctive one of it.

It has been thought that this property of invertase was a life property, and that invertase might exist with different amounts of invertive power; if this is so, it is obvious that invertase could not be estimated by a determination of its invertive power. If, however, the invertive power of invertase is a fixed and definite property of invertase, just as the inverting power of dilute sulphuric acid is a fixed and definite property of sulphuric acid, it will be possible to estimate invertase by a determination of its invertive power. To determine this and to discover the laws affecting the action of invertase on cane sugar, the authors have made a large number of experiments under varying conditions. The experiments were in general conducted as follows:—A weighed quantity of cane sugar was dissolved in boiling water, and the solution made up to a definite bulk at 15.5° C., space being left for the invertase solution. The solution was placed in a covered vessel kept at a

constant temperature, and a weighed quantity of a preparation of invertase added and allowed to act on the cane sugar for a definite time. At the conclusion, the inversion was stopped by adding one drop of concentrated potash, and the optical activity observed after an interval of 15 minutes or so.

### THE ACTION OF INVERTASE ON CANE SUGAR.

*Rapidity of the Reaction.*—Three series of experiments were made, one at 15.5° C., one at 35.5° C., and one at 54° C. The results are plotted as a curve, the ordinates representing the percentage of sugar inverted and the abscissae the time units. One time unit is the time taken to invert 10 per cent. of the sugar. The three curves do not materially differ from the curve representing a simple chemical action in which no condition varies but the diminution of the changing substance; there is however a slight divergence.

*Influence of the Proportion of Invertase present.*—Unless the solution contain that amount of sulphuric acid necessary to produce the most rapid inversion (see influence of sulphuric acid), no intelligible results can be obtained; but if this condition is observed, it is found that the time necessary to reach any given percentage of inversion is inversely proportional to the amount of invertase solution employed, *i.e.*, to the amount of invertase. Experiments were made at 15.5° C. and 56.5° C. The results of these experiments were expressed by the number of minutes required to reach the point of no optical activity, that is 74.1 per cent. of cane sugar inverted. These numbers were calculated from the experimental results as follows. From the observed optical activity of the partially inverted solution, the percentage of inversion was calculated; by referring to the curve expressing the rapidity of the action, the number of time units are found which are equivalent to this percentage of inversion. The same curve shows that the point of no optical activity is reached in 12.7 time units. Knowing how many minutes it took to reach the observed optical activity and which have been found to be equivalent to so many time units, a simple proportion will give the number of minutes equivalent to 12.7 time units, that is the number of minutes required to reach the point of no optical activity. For the sake of convenience this is expressed by  $\pm 0 = n'$ .

*Influence of Concentration of the Solution.*—These experiments were made with yeast as the inverting agent at 54° C., and the results calculated in accordance with the previous experiments to the point of no optical activity and a constant amount of invertase. The most favourable concentration was found to be of solutions containing 20 grms. of cane sugar per 100 cc. of solution.

*Influence of Temperature.*—The results were calculated to the number of minutes required to reach the point of no optical activity with 0.1 gm. of invertase preparation, the calculations being made as above explained. The results were plotted as a curve, the temperature being represented on the ordinates and the number of minutes as above, on the abscissae. The curve agrees at low temperatures with that representing a simple chemical reaction taking place at varying temperatures. At high temperatures, the inverting power is much less than it should be if this simple relation held. The authors point out that these temperatures approach very near the point at which the invertase is destroyed, and that this is probably the explanation of the discrepancies.

*Influence of Alkalis.*—Small amounts of alkali completely destroy the inverting power. If a solution of cane sugar undergoing inversion, be "stopped" by a small quantity of alkali, the optical activity is found to decrease on standing, attaining a constant value in about 15 minutes. If a larger quantity of alkali is used, this constant value is reached instantaneously. It is, then, evident that this decrease when using a small quantity of alkali is not due to inversion continuing for a further short time. Additional proof of the truth of this has been derived from determinations of the molecular weight of solutions of cane sugar undergoing inversion, the molecular weight thus determined agrees

with that calculated from the constant value of the optical activity after "stopping" with potash at the moment at which the freezing point was determined, and does not agree with the value of the molecular weight as deduced from the optical activity possessed by the solution at the moment at which the freezing point was determined. This is perfectly analogous to the case of "bi-rotating" dextrose. The molecular weight of such bi-rotating solutions being the same as when the constant value of the optical activity has been reached, and it was found that small quantities of concentrated potash instantaneously destroyed the bi-rotation of dextrose solutions, there can therefore be no doubt that the dextrose is liberated in the bi-rotating state, when cane sugar is inverted in the cold by invertase.

**Influence of Sulphuric Acid on the Speed of Inversion.**—Small quantities of acid greatly increase the rapidity of inversion, larger quantities retard it. It is of great importance to determine the most favourable quantity of acid, and a great number of experiments were made for this purpose. It was found that this varies with the temperature and amount of invertase.

The following table expresses the most important results:—

Invertase Solution, Per cent. on the Sugar.	Most favourable amount of Sulphuric Acid, expressed as Parts of SO <sub>3</sub> per 100,000 of Solution.	
	Temp. 15.5° C.	Temp. 56° C.
0.4	..	1.25
0.7	..	1.25
1.5	7.5	1.5
4.5	15.0	..
15.0	25.0	..

**Influence of Alcohol on the Speed of Inversion.**—This varies in arithmetical progression with the amount present; it retards the reaction. This is in accordance with the influence of foreign bodies on simple chemical reactions.

**Amount of Inverting Power.**—This is practically unlimited. In one experiment, 1 part of invertase inverted 100,000 parts of cane sugar.

From the above experiments it is evident that the action of invertase on cane sugar is a definite and measurable quantity, and that in many ways it follows the course of a simple chemical reaction of which no condition varies but a diminution of the changing substance. The following method for estimating invertase is deduced from the above-described experiments.

Fifty grms. of cane sugar are dissolved in water to nearly 250 cc. and put in a water-bath kept at 15.5° C. When the temperature is constant, 0.5 gm. of the invertase containing preparation is added and the time noted. The solution is quickly made up to 250 cc. and divided fairly equally amongst five beakers which are placed in the water-bath. To the contents of each beaker different amounts of sulphuric acid are added. Under ordinary conditions the amounts may be 0.1, 0.3, 0.6, 1.0, and 1.4 cc. of decinormal sulphuric acid. After standing one hour at 15.5° C., a small quantity of the solution in the third beaker is taken and stopped by a drop of potash, the time noted, and the optical activity determined, and the time required for the solution to reach the point of no optical activity is calculated as explained above. When the calculated time approximately arrives, the inversion in each beaker is stopped by a few drops of potash, the time being accurately noted. After standing a quarter of an hour the optical activity of each solution is determined. If the lowest optical activity is possessed by the solution containing the least or greatest quantity of sulphuric acid, the experiments must be repeated with more suitable quantities of sulphuric acid; if one of the other three solutions has the lowest optical activity, this one is calculated as above explained to the number of minutes required to reach the point of no optical activity.

In some cases it is necessary to vary the conditions from those given above. In the case of yeast, good results can only be obtained at a higher temperature, 54° C. is most convenient; much smaller quantities of sulphuric acid are required; the amounts may be 0.0, 0.05, 0.1, 0.2, 0.3 cc. of decinormal acid for the five beakers. The results multiplied by 7.5 will bring them to the standard temperature of 15.5° C.

The results of a number of determinations made under varying conditions show that constant and reliable numbers are obtained.

#### THE PREPARATION OF INVERTASE.

If sound pressed brewers' yeast be kept in a lightly covered vessel in a warm place it liquefies, but even after several months does not putrefy. If after standing some weeks the liquid be filtered, almost the whole of the invertive power is found to be possessed by the filtrate; and from this alcohol precipitates a syrupy precipitate possessing high invertive power. This precipitate if dissolved in water and filtered yields a solution of invertase which, if a little alcohol be added, will often retain its invertive power for long periods. The residue on the filter is yeast albuminoid.

Full details for preparing the most active preparation are given in the original paper. The following analysis of liquefied yeast is given, which was obtained on allowing pressed yeast to stand for a month in a warm place:—

	Per Cent. on Dry Solid Matter of Yeast.	Grms. per 100 cc. of Solution.	Inverting Activity Calculated on the Yeast Liquor ± 0 =
Cellulose and other insoluble organic matter.....	22.80	..	..
Organic matter soluble in 17 per cent. alcohol .....	56.53	17.72	None.
Yeast albuminoid.....	5.93	1.86	None.
Organic matter insoluble in alcohol and soluble in water (invertase) .....	5.81	1.82	1380'
Ash.....	8.93	2.80	..
Total .....	100.00	24.2	1210'

The invertase above was the most active preparation obtained, and had an activity  $\pm 0 = 25.1'$  (calculated on the dry preparation). From the invertase solution the ash could be separated by dialysis in presence of dilute hydrochloric acid without impairing the activity of the invertase; it was difficult to remove the whole of the ash in this way as the solution began to decompose before the whole of the ash could be dialysed out. The invertase solution, as obtained above, could not be further purified, any attempt at fractional precipitation with alcohol destroying its invertive power. The most active preparations are very unstable; less active ones may be sometimes kept for years without material diminution of their inverting power.

**Yeast Albuminoid.**—As has been stated above, when the precipitate, obtained by adding alcohol to yeast liquor, is dissolved in water, invertase dissolves and a precipitate remains called yeast albuminoid; this resembles other albuminoids; it contains about 15 per cent. nitrogen, it is soluble in alkaline solutions, and is reprecipitated by acids.

#### THE INVERTAN SERIES.

Solutions of invertase having an inverting power expressed by the formula  $\pm 0 = 25' - 30'$  have an optical activity of  $[\alpha]_D^{20} = 70^\circ - 74^\circ$ , and contain 3.5—3.9 per cent. nitrogen. The substance in solution is called  $\beta$ -invertan. When any attempt is made to purify this by fractional precipitation with alcohol, the invertive power is destroyed

and the optical activity sinks to about  $[\alpha]_D = 54^\circ$ , and the fractional precipitates are partly soluble and partly insoluble in water; it is therefore evident that the invertase has been decomposed.

The insoluble body is called *α-invertan*; it is obtained as a crumbly precipitate; it contains 8.35 per cent. of nitrogen, and its optical activity is  $[\alpha]_D = -11^\circ$  to  $-20^\circ$ . If *α-invertan* be dissolved in potash and an alkaline solution of a copper salt and a large excess of potash added, a precipitate is thrown down, from which *ζ-invertan* may be prepared (q.v.); on acidifying the clear solution and adding alcohol a precipitate is obtained, which, when purified, is found to be identical with yeast albuminoid.

The soluble body is called *δ-invertan*, it is obtained as a syrupy precipitate; it contains 2.4 per cent. nitrogen, and has an optical activity of  $[\alpha]_D = 54^\circ$ . If it is fractioned several times by alcohol in the presence of acid it splits up into *α-invertan* and *ε-invertan*.

*ε-invertan* is also sometimes obtained directly in the fractionation of invertase, especially if much acid is present; it contains 2.07 per cent. nitrogen and has  $[\alpha]_D = 65.2^\circ$ . If it is often fractioned by alcohol and acid it breaks down into *ζ-invertan*, and an insoluble body resembling *α-invertan*, which yields *α-invertan* on purification.

*ζ-invertan* may also be obtained from *α-invertan* by forming the copper compound in the presence of a large excess of alkali, and the copper subsequently removed by hydrochloric acid. *ζ-invertan* is very stable, and can be fractioned by acid alcohol repeatedly without alteration. It contains 1.6 per cent. nitrogen, and has an optical activity  $[\alpha]_D = 75^\circ$ . It is broken down slowly when boiled

with dilute sulphuric acid. After boiling  $1\frac{1}{2}$  hours a body is obtained similar to the others of the invertan series, and called *η-invertan*; it contains 1.05 per cent. nitrogen and has an optical activity  $[\alpha]_D = 75.7^\circ$ .

All the invertan compounds yield with an alkaline solution of copper oxide a voluminous precipitate difficult to purify, and containing quantities of copper varying from 14–32 per cent. CuO. All the bodies thus obtained from invertase are evidently intimately related. The purest sample of *β-invertan* (invertase) had an inverting power expressed by the formula  $+0 = 25.1^\circ$ , and as this solution contained nothing but invertase, and the bodies obtained when invertase is decomposed as above, over 80 per cent. being invertase, the inverting activity of pure invertase would be expressed by the formula  $+0 = 22.5^\circ$ . Invertase is a white powder, which, when dry, will withstand the action of a temperature of  $100^\circ\text{C}$ . without much loss of inverting power. In solution its inverting power is diminished by very moderate temperatures and completely destroyed by exposure to a temperature of  $50^\circ\text{C}$ .; but in the presence of a large quantity of cane sugar it can withstand a temperature of  $60^\circ\text{C}$ . without loss of inverting power; this is, however, completely destroyed at  $75^\circ\text{C}$ . The composition of the invertan compounds agrees well with a theory that they are members of a series, each one being a compound of yeast albumen and a carbohydrate.

The following table shows their relation:—

A represents 1 part by weight of albuminoid and 8, 1 part by weight of carbohydrate, *α* represents *α-invertan*, that is  $\Lambda_1S_3$ , *η* represents three times *η-invertan*, that is  $3\Lambda_3S_3$ , so that *η* represents 57 parts by weight and *α*, 7 parts by weight:—

Name of Substance.	Inverting Power, $\pm 0 =$	Optical Activity of $[\alpha]_D =$	Constitution.	Composition Parts by Weight.	Composition According to Theory.			Composition Found.		
					C	H	N	C	H	N
<i>α-invertan</i> .....	$\infty$	$-15^\circ$ (Approx.)	<i>α</i>	$\Lambda_1S_3$	43.41	6.90	8.30	48.06	6.65	8.35

It has already been shown that in the inversion of cane sugar by invertase, the invertase is unaltered. The authors are inclined to consider that the invertase forms a loose compound with cane sugar and water and that this breaks down into invert sugar and invertase.—A. L. S.

actually give. If the other sugar was really galactose, treatment with nitric acid should produce mucic acid. As much as 57.3 per cent. of mucic acid was obtained.

Thus peach gum from either bark or fruit contains certain substances which on hydrolysis yield arabinose and galactose.

—T. L. B.

#### *The Carbohydrates of Peach Gum.* W. E. Stone. Ber. 23, 2574–2576.

WHEN the skin of unripe peaches or the bark of the tree is broken a peculiar gum oozes out, that from the bark being browner than that from the fruit. The presence of a carbohydrate giving galactose, as indicated previously by Bauer, was confirmed in both forms of gum by recognising the presence of furfural and of mucic acid. Evidence was obtained, however, of the presence of a second substance, which on hydrolysis yielded a pentaglucose. To isolate the carbohydrates the gum was heated for 9–10 hours on a water-bath with dilute sulphuric acid (sp. gr. 1.03), the yellow liquid was neutralised with barium carbonate, filtered, and evaporated to a syrup, which crystallised in the course of a few days. Fractional crystallisation was resorted to and the products were examined polarimetrically. In this way products were obtained which, from their specific rotatory power, pointed to the presence of arabinose and galactose. The supposed arabinose should, when distilled with dilute sulphuric acid, give furfuralamide, and this it did

#### *The Composition of Vegetable Cell-Membranes.* E. Schulze. Ber. 23, 2579–2583.

It is well known that many vegetable cell-membranes contain besides true cellulose other carbohydrates which are quickly converted by dilute mineral acids into mannose, galactose, or penta-glucoses. The question arises whether the portion of the cell wall unacted on by dilute acids, and which is generally looked on as true cellulose, furnishes only dextrose on hydrolysis. To decide this point the author has prepared cellulose from various seeds &c., including peas and lupin seeds, coffee beans, wheat bran, cocoa-nut kernels, and lupin shells, by treating these bodies successively with the following solvents: ether, dilute potash, and dilute acid. In some cases cold dilute nitric acid and potassium chlorate were also used. The remaining cellulose was in each instance converted into glucose by treatment with strong sulphuric acid. All the glucose syrups obtained furnished more or less saccharic acid on oxidation with dilute nitric acid, and the preparations from lupin seeds and shells, and wheat bran yielded crystals of dextrose, which was

identified by its optical activity and other properties. The cellulose from lupin shells, although apparently quite pure, was stained an intense violet-red colour when boiled with hydrochloric acid and phloroglucinol. The stained cellulose placed in a 50 per cent. solution of chloral imparted to the latter a similar violet colour. This behaviour could certainly not be due to the presence of lignin, since that body would be all extracted from the cellulose during the purifying process. The cellulose from lupin shells also yielded appreciable quantities of furfural on distillation with sulphuric acid. The glucose from coffee-bean cellulose was found to contain besides dextrose a considerable amount of mannose. Traces of mannose were also present in the preparation from cocoa-nut kernels. None of the glucose syrups contained either galactose or penta-glucoses.

—H. T. P.

*Fucose.* A. Günther and B. Tollens. Ber. 23, 2585—2587.

THE authors have continued the research—commenced by Bieler and Tollens—on fucose, which is prepared from the "fucus" (seaweed). They have obtained the sugar in the crystalline state, by first converting the raw sugar into the corresponding hydrazone, the latter, being, after purification, decomposed in the manner described by Fischer and Hirschberger. The sugar is very soluble, is sweet, and crystallises slowly, forming microscopic needles and plates, having the composition of rhamnose,  $C_6H_{12}O_5$ . Fucose is strongly levo-rotatory and exhibits the phenomenon of bi-rotation. The rotatory power of a freshly-made solution is  $-112^\circ$ , which gradually falls to  $-77^\circ$ . On distillation with hydrochloric acid, fucose yields methyl-furfural. Fucose strongly reduces Fehling's solution; 1 cc. of Fehling's solution = 6—7 mgrms. of fucose. With phloroglucinol, resorcinol, and orcinol, fucose gives merely a yellow solution. The hydrazone and osazone of fucose melt at  $170^\circ$  C. and  $159^\circ$  C. respectively.—H. T. P.

*On the Optical Isomers of Dextrose, Gluconic Acid and Saccharic Acid.* E. Fischer. Ber. 23, 2611—2624.

JUST as *d*-mannonic acid may be converted into *d*-gluconic acid, which may be reduced to *d*-glucose (dextrose) (Ber. 23, 800; this Journal, 1890, 528) so in the same way by heating *l*-mannonic acid (arabinose-carboxylic acid) with quinoline it is converted into *l*-gluconic acid which by reduction yields *l*-glucose. It is, however, difficult to prepare any quantity of *l*-gluconic acid in this way.

In the preparation of *l*-mannonic acid from arabinose, *l*-gluconic acid is also produced, and this is the most convenient source from which to prepare it.

The compound of arabinose and hydrocyanic acid is prepared and saponified by baryta; on removing the baryta by sulphuric acid a mixture of *l*-mannonic and *l*-gluconic acids is obtained; the lactone of *l*-mannonic acid may be almost entirely removed by concentration and crystallisation; *l*-gluconic acid does not crystallise and is soluble in alcohol. The syrup remaining after the separation of the *l*-mannonic acid is diluted and the hydrazide of *l*-gluconic acid precipitated by phenylhydrazine acetate; it is filtered out and purified by treatment with charcoal and crystallisation. The hydrazide is decomposed by boiling with baryta, the phenylhydrazine removed by ether, the baryta removed by sulphuric acid and the acid liquid neutralised with calcium carbonate, and calcium *l*-gluconate precipitated by alcohol and purified by recrystallisation. *l*-gluconic acid,  $C_6H_{12}O_7$ , may be obtained by decomposing the calcium salt by oxalic acid; by boiling with water it is partially converted into the lactone. Neither the acid or lactone crystallise. They are strongly levo-rotatory. The calcium salt is soluble in 3—4 parts of hot water and crystallises from the solution on cooling in cauliflower-like forms strongly resembling the *d*-gluconate. Its optical activity is  $[\alpha]_D^{20} = -6.6$ , being equal and opposite to that of the *d*-gluconate. The acid forms a phenylhydrazide  $C_6H_{11}O_6 \cdot N_2H_2 \cdot C_6H_5$ , melting point  $200^\circ$  C.

In the preparation of *l*-gluconic acid from arabinose as above, 50 grms. of arabinose yielded 20 grms. of pure

*l*-mannonic acid lactone and 8—9 grms. of pure calcium *l*-gluconate; in preparing it from *l*-mannonic acid by heating with quinoline not more than 6 per cent. calcium *l*-gluconate could be obtained; the small yields being due chiefly to the difficulties of purification.

By heating with quinoline, *l*-gluconic acid is partially converted into *l*-mannonic acid; the reaction thus being reversible.

*i*-Gluconic Acid,  $C_6H_{12}O_7$ , is formed by mixing equivalent proportions of *d*- and *l*-gluconic acid. Its properties are similar to those of its components. The calcium salt is very characteristic, being less soluble than the corresponding salts of its component acids. The acids and its salts are optically inactive. It forms a hydrazide,  $C_6H_{11}O_6 \cdot N_2H_2 \cdot C_6H_5$ , melting point  $188^\circ$ — $190^\circ$  C. Analogously to its components it may be formed by heating *i*-mannonic acid with quinoline.

*l*-Glucose,  $C_6H_{12}O_6$  is formed by reducing the lactone of *l*-gluconic acid by sodium amalgam in acid solution. The reduced solution is made alkaline, filtered, neutralised and evaporated until the sodium sulphate begins to crystallise; the syrup is then extracted with alcohol. The alcoholic solution on evaporation yields the sugar as a syrup, which crystallises on standing. It may be purified by recrystallisation from methyl alcohol. It resembles dextrose very closely except that it is not fermentable. Its action on polarised light is equal and opposite to that of dextrose.

*i*-Glucose,  $C_6H_{12}O_6$ , is formed by mixing equal quantities of *d*- and *l*-glucose or by the reduction of *i*-gluconic acid. It resembles its components closely. Yeast ferments it partly and leaves *l*-glucose.

*l*-Saccharic Acid,  $C_6H_{10}O_8$ , is formed just as ordinary saccharic acid by oxidising *l*-gluconic acid by nitric acid, and is isolated as its calcium salt. It forms an acid potassium salt,  $C_6H_9O_8K$ , crystallising in bundles of needles. The silver salt,  $C_6H_7O_8Ag_2$ , is insoluble. It forms with phenylhydrazine a double hydrazide melting point  $214^\circ$ . The acid and all its compounds are levo-rotatory.

*i*-Saccharic Acid,  $C_6H_{10}O_8$ , is formed by mixing solutions of equal quantities of *i*- and *d*-saccharic acid; or by oxidation of *i*-gluconic acid. It forms a double hydrazide melting point  $209$ — $210^\circ$  C. The acid and its compounds are optically inactive.

The acid potassium salt is characteristic of the three saccharic acids; the crystalline form of the inactive salt may be easily distinguished from that of the other two. All three are distinguished one from the other by their optical activities, the rotation for the two active salts being greatly increased by acidifying.

When an organic compound containing an asymmetric carbon atom is formed synthetically an inactive substance is always obtained which is either a combination of two active substances or inactive by internal compensation as inactive tartaric acid. In the case of the acids produced from arabinose by the hydrocyanic reaction the last case is not possible, as arabinose is not symmetrical, but according to Le Bel and Van't Hoff's theory three acids are possible, two with the carbon atom, marked with a star oppositely asymmetrical,  $CH_2(OH) \cdot CH(OH) \cdot CH(OH)CH(OH) \cdot CH(OH) \cdot COOH$ , and a third, a combination of these two. Two of these are known, i.e., *l*-mannonic and *l*-gluconic acids, but they do not appear to combine to form the third. The author has attempted to form a combination of *d*-gluconic and *d*-mannonic acid, but also with no success. It appears that these inactive compounds are only formed between two compounds such as *d*- and *l*-gluconic acid, in which all the carbon atoms are asymmetrically opposite.—A. L. S.

*On some Acids of the Sugar Group.* E. Fischer. Ber. 23, 2625—2628.

*The Lactone of d-Gluconic Acid* may be obtained from calcium gluconate by removing the calcium by oxalic acid and evaporating the acid solution on the water-bath as far as possible; the syrup is placed over sulphuric acid, and in 8—14 days fine needle-shaped crystals separated. The crystals are the lactone of *d*-gluconic acid,  $C_6H_{10}O_6$ , and may be purified by recrystallisation from water. The

crystals melt at  $130^{\circ}$ – $135^{\circ}$ , and are easily soluble in alcohol. It is dextro-rotatory and more so than *d*-mannonic acid lactone;  $[\alpha]_D = 68.2$ , solutions of *d*-gluconic acid are levo-rotatory, but they soon become dextro-rotatory owing to the formation of the lactone.

*Calcium L-Mannonate* is prepared by boiling calcium carbonate with an aqueous solution of *L*-mannonic acid lactone; the filtered solution is evaporated to a small volume and as much alcohol added as possible without precipitating the hot solution. On cooling a syrup falls out, which on standing crystallises.

*Arabonic Acid Phenylhydrazide*,  $C_5H_9O_5 \cdot N_2H_2 \cdot C_6H_5$ , is prepared by heating a solution of arabonic acid or its lactone with an equal weight of phenylhydrazine and 50 per cent. acetic acid for  $1\frac{1}{2}$  hour on a water-bath. On cooling the hydrazide crystallises out, the yield being nearly quantitative. Recrystallised it forms colourless, shining leaves, melting point,  $215^{\circ}$ .

*Xylose Carbonylic Acid* is prepared by the action of hydrocyanic acid on xylose and saponification of the product by baryta. The barium salt,  $C_5H_{11}O_7 \cdot BaOH$ , is difficultly soluble in cold water, and crystallises on cooling from its solution in hot water; decomposed by sulphuric acid it yields an acid, which, when reduced by sodium amalgam yields a sugar not as yet identified with any of the known hexoses.—A. L. S.

#### *Purification of Waste Water from Sugar Refineries, &c.* H. Schreib. Chem. Zeit. 14, 1323–1324.

THE following method for the purification of the waste water of sugar refineries, &c. has been recommended by the Austrian Government inspector:—

The water, after being cleared by the addition of "chemicals," is filtered and pumped to an elevated reservoir, from whence it is allowed to flow over wire gauze for the purpose of thorough aeration, whereby the organic matters are presumed to become oxidised. That such oxidation takes place to only a very limited extent is proved by the results obtained by the application of several other methods having the same object in view. Storer's method, patented in 1880, appears to oxidise about 7 per cent. of the organic substance present; by Leeds' method, according to König, the water contained 17 per cent. of free oxygen and 53 per cent. of carbonic anhydride more than before treatment with air; the results of Knauer's method show that calcium carbonate becomes precipitated in the apparatus, but that the amount of organic substance is not materially reduced, and results obtained by the author with a method in which the water flowed over wire gauze showed that there was practically no change effected in the organic substance present.—J. W. L.

#### *Contributions to a Knowledge of the so-called Nitrogen Free Extract of Barley, particularly in Malt and Beer.* C. J. Lintner. Zeits. f. angew. Chem. 1890, 519–522.

ONE part of barley malt was digested with five parts of water for one day, filtered and washed with water. The filtrate was concentrated whereby some albuminoids were precipitated, filtered from these and alcohol added as long as a precipitate was formed. The precipitate was washed with ether, dried and dissolved in potash solution, the solution was filtered and a solution of copper sulphate added to the filtrate. A precipitate was thrown down, this was washed with water, until all the alkali was removed; it was then dissolved in concentrated hydrochloric acid and the gum precipitated by alcohol, redissolved and reprecipitated once or twice in the presence of hydrochloric acid until free from copper; it was then dehydrated with alcohol washed with ether and dried first in vacuo over sulphuric acid, and then in a current of dry air at  $110^{\circ}$  C. A similar product may be obtained from beer. It is a white powder, non-hygroscopic, and soluble in water to a cloudy solution, having a strongly acid reaction, not reducing Fehling's solution, and rotating the plane of

polarisation to the left  $[\alpha]_D = -27$  approx. After digestion with dilute acid the solution reduces Fehling's solution and becomes dextro-rotatory, but the nature of the sugar or sugars formed was not determined. A determination of the carbon and hydrogen of three different samples gave C = 42.5 to 39.8 per cent., H = 7.5–6.9 per cent. The author is inclined to consider it to have the formula—

It gives several of the reactions which are common to arabinose and xylose and bodies which yield these sugars on hydrolysis, i.e., it yields furfural on boiling with sulphuric acid, it gives with phloroglucinol and hydrochloric acid a cherry-red colouration.

A similar gum occurs in all grains, and a gum is also obtained by treating as above a solution of yeast in boiling water.—A. L. S.

#### *The Transformation of Glucose into Sorbite.* J. Meunier, Compt. Rend. 111, 49–51.

THE author has investigated the action of sodium amalgam on glucose, and describes a method for the preparation of sorbite from glucose by the action of sodium amalgam. A yield of 35–40 per cent. of sorbite has been obtained.

—H. T. P.

#### *Note on the Hydrogenisation of Sorbin and the Oxidation of Sorbite.* C. Vincent and Delachanal. Compt. Rend. 111, 51–53.

THE authors have converted sorbin by reduction into sorbite from which it differs by two atoms of hydrogen; but have not been able to reverse the process, viz., convert sorbite by oxidation into sorbin.—H. T. P.

#### *Automatic Apparatus for Sugar Refineries.* P. Horsin-Déon. Bull. Soc. Chim. [3], 4, 108–112.

*Automatic Measurer.*—This apparatus registers the amount of juice in the measuring back at any time, the time at which it was full, and the time at which it was emptied. The apparatus consists of a float in the measuring back which communicates by a light cord with the apparatus proper. The end of the cord is attached to a reel round which it winds. This reel is furnished with a pin which communicates a vertical motion to a copper rod, which carries a pen or pencil writing on a paper stretched round a revolving drum. The copper rod makes an electrical contact at its highest and lowest positions, which causes a bell to ring. The positions of these contacts are so arranged that they correspond to the empty and full state of the measuring back. There is also a counter which moves forward one unit every time the lowest contact is made, that is, every time the measuring back is emptied, thus registering the number of times the back is emptied.

*Registrating Densimeter.*—This consists of two chambers connected by a tube; the outside end of each chamber is closed by a sheet of caoutchouc. The whole is filled with water and placed vertically in a vessel in which the juice passes in at the bottom and out at the top, so that the height of the liquid is constant. It is evident that if the density of the liquid in the outer vessel increases there, the pressure on the water in the chamber and tube will increase, and the top sheet of caoutchouc will bulge out. This sheet is connected with a system of levers, which carry a pencil writing on a revolving drum, so that the position of the caoutchouc sheet is registered, that is, the density of the liquid passing through the outer vessel is registered. As the water in the chambers and tube is at the same temperature as the liquid passing through the outer vessel, no correction for temperature is necessary.

*Automatic Sampler.*—As the strength of the juice may not be uniform throughout the vessel from which the sample is taken, some arrangement is necessary that the sample taken may be of the average strength of the whole body of liquid. The sampler consists of a tube open at both ends and as long as the back is high. This is placed vertically in the back and fills as the back fills. The contents

of the tube will evidently be a true sample of the contents of the back. The lowest end of the tube is furnished with a three-way cock moved by a float. Whilst the back is filling the cock is placed so that the tube is in connexion with the liquid in the back. When the back is full the float alters the tap so that the contents of the tube flow out through a side tube into a vessel placed to receive them.

—A. L. S.

#### PATENTS.

*Improvements in or relating to Apparatus for Drying Sugar-Cane Trash.* A. J. Boulton, London. From L. Bon, Guantamano, Cuba. Eng. Pat. 4754, March 26, 1890. 6d.

This invention relates to apparatus whereby green sugar-cane trash may be rapidly dried and made available for use as fuel. The apparatus can only be intelligibly described by reference to the drawings accompanying the specification.

—A. J. K.

*Improvements in Sugar Refining.* H. Lake, London. From L. Stenberg, New York, U.S.A. Eng. Pat. 12,635, August 12, 1890. 6d.

A solution of cane sugar of  $10^{\circ}$  to  $15^{\circ}$  B. which contains glucose is boiled for about two hours with caustic lime, strontia, or baryta (preferably lime) in the proportion of 15 to 30 per cent. of lime on the weight of dry sugar plus the weight of glucose present. By this means the glucose is decomposed, and the products of decomposition form with the alkaline earths compounds which are insoluble so long as the solution remains alkaline. In addition to these insoluble compounds, which can be removed immediately by means of a filter-press, there are also formed soluble bodies which may be precipitated by treatment in a "blow-up" with carbonic acid, and finally certain liquid bodies which cannot be thus precipitated, but which are not injurious, because they do not interfere with the crystallisation of the cane sugar. This process is recommended as a useful preliminary to those processes in which low grade syrups are purified by means of lime or strontia and carbonic acid, such as the so-called lime process described in U.S. Pat. 270,879 of 1881.—A. J. K.

## XVII.—BREWING, WINES, SPIRITS, Etc.

*On the Influence of Various Fruit Ferments (Enzymes) on the Bouquet of Fermented Drinks; and on the Production of a Cider from Barley.* G. Jacquemin. Bull. Soc. Chim. [3] 4, 3—6.

The author refers to a previous paper (Compt. Rend. 106, 643; see also this Journal, 1888, 397), in which, starting from Pasteur's theory that the bouquet of an alcoholic liquor depends on the special enzyme used in its production, he described certain experiments on the improvement of barley wines, and was the first to put this theory to the test on a commercial scale. Later on, in 1888, he showed that barley wines made with the enzymes peculiar to the grapes of Beaune, Chablis, and Riquewyhr (Alsace) possessed the bouquet of the wines of these places. M. Quénot of Nancy has, with the author's help, produced in a similar way, on a commercial scale, raisin wines which cannot be distinguished by the taste from the white wines of Alsace and Chablis.

Since then, L. Marx (a pupil of Hansen's) has published an important memoir in the Monit. Scient. (November 1888), and Rommier has published a note (Compt. Rend. 108, 1322) on the same subject.

In the autumn of 1889 the author used the enzymes of grapes from Ay, in Champagne, from Beaune, Chablis, and Barsac in the making of barley wine. Each experiment was carried out on 60 hectolitres of must in one of the German *Gerstenwein* breweries, and the results showed how largely the special ferment influences the bouquet of the wine. In order to preserve the purified culture of the enzyme, with all its properties, Pasteur has shown that it

must be made dormant by cultivation in a 10 per cent. solution of sugar, which is renewed until fermentation ceases. The dormant ferment kept under the sugar solution becomes active as soon as it is placed in a must containing the necessary elements for its nutrition, such as a grape or barley must. The author has observed that in the period preceding the dormant state, so long as the enzyme acts at all on the sugar solution, the characteristic bouquet is still developed. The decanted sugar solution contains very little alcohol, but nevertheless has a delicious taste, the bouquet being more marked than in the wine itself.

Two practical applications of this discovery are possible:—(1.) Special liqueurs may be manufactured by adding alcohol to the saccharine solutions containing the bouquet of some first-class wine. (2.) These saccharine bouquets may be added by wine-growers to the must for new wines in conjunction with the special enzymes.

The author intends to attempt to isolate the bouquets this autumn by dissolving in ether and carbon disulphide.

*Barley Cider.*—In January 1890, the author isolated an apple enzyme from the lees of a Picardy cider. The cells were pyriform in shape, but on cultivation in a barley must containing tartrate, they become ellipsoidal, like most of the saccharomyces.

This apple enzyme, after purification, was finally employed to ferment 50 litres of barley-must, to which 3 per cent. of citric acid had been added, in order to prevent the competition of undesirable enzymes. The results of the experiment are favourable, and the fermented product possesses the peculiar taste of cider.

Barley-cider contains from 50 to 60 and even 70 grms. of solid extract per litre, and is, therefore, richer than ordinary cider. It contains from 5.5 to 6.5 per cent. of alcohol.

Barley-cider may easily be distinguished from ordinary cider, as a small quantity of a solution of tannin precipitates the tannates of the albuminoids derived from the barley, a reaction which does not take place with ordinary cider.

The new drink, which is more nourishing than cider, will probably replace it—at any rate, during seasons when there is a failure of the apple crop.

The author is continuing his investigations.—P. J. H.

*A New Apparatus for the Manufacture of Pure Yeast.* A. Fernbach. Bull. Soc. Chim. [3], 4, 113—116.

The apparatus consists of a tinned copper vessel furnished with a conical lid, which may be secured to it by clamps (see figure), a perfectly tight joint being produced by an

THE MANUFACTURE OF PURE YEAST.

india-rubber washer. There are two windows in the lid G, through which the contents of the vessel may be seen. Four tubes pass through the lid, one, A, passing to the bottom, and connected with a flattened coil lying on the bottom, and perforated with holes; a second, E, just passing through the lid; a third, D, passing to within 1 cm. of the bottom; and a fourth, C, passing down to a small recess in the bottom.

To use the apparatus, it is filled with a malt extract rich in maltose, and the contents boiled for some time so as to sterilise them and the vessel. The ends of the tubes A and E are connected by india-rubber tubing with short glass tubes loosely plugged with sterilised cotton wool, and the ends of the tubes C and D with short pieces of india-rubber tubing plugged with glass rods. When the apparatus is properly sterilised, the boiling is stopped and the vessel cooled by immersing it in cold water, and a stream of water allowed to trickle over it by the tube F.

When cold, the pure yeast is introduced by the tube E, after carefully removing the plugged glass tube, and replacing it as soon as the yeast is in. The liquid is kept well aerated by drawing a current of air through the apparatus by connecting E with an aspirator, the air entering at A. By this means a large growth of yeast is obtained.

When the fermentation is finished, the yeast is allowed to settle, and the fermented liquid drawn off by D, and then on agitating the liquid remaining, the yeast may be drawn off by the tube C.—A. L. S.

*A New Method for Determining the Amount of Sugar which it is necessary to add to Wines which are to become Sparkling with a Pressure of n-Atmospheres.*

M. E. J. Maumené. Bull. Soc. Chim. [3], 4, 119—122.

A COPPER vessel, silvered inside, is filled with a litre of the wine, and weighed; it is then connected with a manometer, and a reservoir of compressed carbonic acid gas. The absorption of gas is allowed to go on until the manometer indicates a constant pressure equal to the pressure required in the finished wine. The vessel, with the wine charged with gas, is reweighed, and the increase in weight shows the amount of carbonic acid required. The amount of sugar necessary to produce a given amount of carbonic acid is known, and so that the amount necessary in any particular case can be easily calculated. The only alteration in the wine after the fermentation of the added sugar, besides the production of carbonic acid, is the production of a small quantity of alcohol and other bodies, but the effect of these on the absorptive power of the wine is so small that they may be neglected.—A. L. S.

*The Preparation of certain Ethers by Fermentation.*

G. Jaquemin. Bull. Soc. Chim. [3], 4, 256—257.

DURING his studies on lactic fermentation the author has observed that under certain conditions mixed ethers are formed during fermentation. Sterilised barley-wort containing an excess of chalk was sown with a small quantity of a liquid in which a lactic fermentation had been previously started by means of cheese. This liquid contained lactic and butyric ferments and also yeast cells. The wort was contained in a flask so arranged as to permit the escape of gas but not the entrance of air. Some days afterwards the wort was found to possess an ethereal odour, and when distilled yielded a considerable amount of butyric ether and ethyl alcohol mixed with higher alcohols. The residue contained calcium butyrate and a little calcium lactate. A similar fermentation exposed to the air only led to the production of calcium lactate and very little calcium butyrate without any ethers. In another experiment, sterilised barley-wort was sown with a pure cultivation of the lactic ferment. After eight days' fermentation in presence of chalk and of pure air, a pure cultivation of *Saccharomyces ellipsoideus* was added, with the result that lactic ether was formed. The production of ether is probably owing to the facility afforded to the alcohol and acid of acting on each other whilst in the nascent state.

—H. T. P.

*New Uses for Fluorides and Hydrofluoric Acid.* Chemist and Druggist, 1890, 542.

J. EFFRONT, of Brussels, has described a number of experiments showing the beneficial influence of fluorides and hydrofluoric acid on diastase and yeast during the saccharifying and fermenting processes. In view of modern discoveries the effect seems to be one of selection, fluorides impeding or preventing the formation of lactic and butyric ferments, and thereby promoting pure alcoholic fermentation. Effront has succeeded in obtaining from maize 96 per cent. of the theoretical amount of maltose and 4 per cent. of dextrin, the solution yielding by simple evaporation crystallised maltose. The proportion of acid needed is very small, but not quite clearly stated. The temperature preferred is 30° C. instead of 50° C. as usual. To produce alcohol the author prefers potassium fluoride. He has found that with the addition of the fluoride maize may, without previous saccharification, be fermented at once after boiling to dissolve the starch and cooling. As a typical experiment, 9 kilos. of maize, 1 kilo. of malt, and water enough to make 54 kilos. of mash, on being, with 270 grms. of yeast and 27 centigrams. of potassium fluoride, set to ferment for three days at a temperature of 30° C., will yield in alcohol 63.26 per cent. of the weight of dry starch contained in the materials, while, under most favourable circumstances, the alcohol obtainable without fluoride averages 41 to 42 per cent. Another advantage claimed for the process is that, no butyric acid forming during the fermentation, the spirit obtained is free from unpleasant taste and smell. The process has been patented (this Journal, 1890, 960; Eng. Pat. 16,093 of 1889).

*Report on Wines.* Report of the Central Laboratory of the Italian Customs Department, 1836—1889, 3—59.

A SHORT time ago an extensive fraud on the Italian Customs was detected and exposed by the work of the laboratory. From Switzerland and Austria-Hungary so-called Cyprus, Samos, Smyrna, and Cephalonia wines were imported, but these liquids, generally of a musty odour, consisted of water, alcohol, and cane sugar; a red wine was made up by the addition of an aniline dye. These mixtures were worked up with suitable drugs and exported as vermouth. A double fraud was thus committed, *firstly*, on importation, when the liquids were assessed as wines and not as spirits; and, *secondly*, on exportation, when a claim was made for repayment of the duty on alcohol, a duty which had, however, never been paid. Analytical results are given of these mixtures, and the results compared with those of wines of undoubted genuineness.

In order to pass a judgment rapidly upon a sample the administration of the laboratory determined the proportion of alcohol by weight and by volume and the amount of sugar after inversion. The results are also given for the alcohol, by weight and volume, the grape sugar saccharose, and dry extract without sugar of 437 samples of typical genuine wine. It is also pointed out in the report that in the old Custom house tariff no definition was given of the word "wine," but in the recent (1888) regulations it is defined as follows:—

"Wine is the natural product of the fermentation of grape juice; under spirituous liquors shall be included so-called wines which contain saccharose, or other matters not contained in natural wines, as also those which are wanting in any of the characteristic components of wines, or which contain a quantity of these components in excess of the limits met with in natural wines or of the limits of the reciprocal relations found in these wines. Natural wines, of alcoholic strength of more than 15° shall pay, in addition to the proper duty on wine for every degree exceeding such a limit, the duty and surcharge on alcohol in the ratio of a litre of anhydrous spirit per degree and per hectolitre. Fractions of a degree less than five-tenths shall pass, in excess of five-tenths shall be counted as one degree."

The Department points out that in accordance with this definition the analysis of disputed samples of wine must be as complete as possible, so as to include not only artificial

beverages but also natural wines which have been sophisticated with water, alcohol, sugar, or glycerol. The method of analysis laid down by the German Imperial Commission of 1884 has been adopted, together with certain modifications proposed by the Austrian Wine Congress at Bozen (1887). Analyses made by these methods of 328 samples are given in a series of tables.

The beneficial effect of the work of the laboratory is shown in the relation of importation of wine and exportation during the last few years. In 1886 the importation of wine was about 300,000 hectolitres, and the exportation rose to 253,367 hectolitres. In 1887, when the fraud of the Cyprus wines was detected, the importation decreased to 132,520 hectolitres, though the duty remained the same. Again, from January 1st to June 30th, 1888, the importation was 24,670 hectolitres, but in the same period in 1889, under more rigorous regulations, the importation decreased to 5,604 hectolitres, a diminution traced, however, not only to the causes above mentioned, but also to others without the sphere of the laboratory.—V. H. V.

*Report on Syrups.* Report of the Central Laboratory of the Italian Customs Department, 1886—1889, 282—286.

The tariff report defines syrups generally as juices of fruit to which sugar has been added. If the juices of the fruit are natural they are classed in Category III. as orange juice, crude juice of citron and lemon, and concentrated juice of citron and lemon.

The report further lays down that "juice of orange, pine apple, berry, raspberry, pomegranate, ribes, prickly grape, and the like," pay as "orange juice"; "juice of orange, pine apple, &c. as above mixed with sugar, without alcohol pay as drinking syrups."

Juice of cherries, apples, and pears, fermented or not fermented, included as "elder," are classed with "wine." With syrups is also classed "carmine acid, mixed with sugar, which serves to colour saccharine matters," but syrups containing medicinal compounds are classed as medicines.

Analyses are given of samples sent, and two cases are specially mentioned of very intensely red liquids, of strong acid reaction, the one possessing the odour of pomegranate, the other of raspberry. It was stated on the labels of the bottles that syrup of pomegranate and raspberry could be prepared by adding one litre of the liquid to 100 litres of syrup of sugar. The Direction of the laboratory could not discover, however, the artificial colouring matter, and as no direct evidence could be obtained, these liquids were passed as fruit juice. Another sample was designated as a syrup of carabes and dried figs. The Government inquired if such a syrup might not be used as a substitute for starch syrup or even instead of glucose, in which case it should pay a manufacture tax. The laboratory replied that though it resembles an adulterated syrup of glucose, yet it should not be subjected to a manufacture tax. The product might be used as an inferior kind of food, but not for the manufacture of liquors or syrups; it might be used for certain industries, and even for the manufacture of alcohol.

—V. H. V.

*Report on Spirits.* Report of the Central Laboratory of the Italian Customs Department, 1886—1889, 59—64.

The tariff report distinguishes between "pure spirit and and sweetened or aromatic spirit," including rum, brandy, &c. In the former class are included those which have undergone no special preparation and are not extracts of substances which can impart an aroma to the distillate, while in the second are included liquids having alcohol as their bases and which are not classed under medicines, drugs, and essences.

Spirits, whether pure or not, are taxed according to the proportion of ethyl alcohol therein contained and determined by the official alcoholometer.

Disputes have arisen as to the difference between pure and sweetened spirit, especially if the samples are coloured yellow; an examination is then made to determine whether

the residue left on evaporation consists of tannin, derived from the wood of the containing cask, or of sugar. A liquid consisting of an alcoholic solution of cadmium, bromides, and iodides used in photography, was classed under sweetened and aromatic spirits. The laboratory has also been engaged in questions regarding a *manufacture tax* upon certain manufactured products obtained by extracting lees of wine with spirit; thus, as regards certain samples of various liquids of a red colour, the officials were in doubt as to whether wine had not been fraudulently added, while the importers maintained that the colour and vinous odour were derived from the wine casks in which the liquids had been kept. It was decided in favour of the latter side. Analyses are given of the various samples sent.

*Vermouth.*—This liquid is practically not imported into Italy. On exportation a *drawback* is made for the spirit and saccharose which it contains, it being supposed that the tax has been imposed in the course of the manufacture. The *drawback* for the sugar is settled, not as a result of analysis, but for a fixed proportion of 5 kilogrammes of saccharose per hectolitre. This drawback was conceded by a Ministerial decree, No. 5310 (Series 2), February 22, 1880, in which it is laid down that no drawback can be allowed unless the liquid contains sugar. The methods adopted for the determination of the sugars (dextrose, levulose, and invert) were the same as those used for wines. In all cases the amount of saccharose was in sufficient excess over the proportion fixed by the tariff for the *drawback*.—V. H. V.

## PATENTS.

*Improvements relating to the Pasteurisation of Beer, Wine, and other Liquids.* W. Kuhn, Clermont-Ferrand, France. Eng. Pat. 15,261A, October 23, 1888. Amended July 18, 1890. 6d

THIS patent (this Journal, 1889, 719), which was previously amended on May 31, 1890 (this Journal, 1890, 880) has been further amended by omitting the word "wine," and inserting the words "like fermentable" before the word "liquids" in the title. The body of the specification is amended in accordance, so that it only relates to beer and similar liquids.—A. L. S.

*Improved Processes of Maturing and Mellowing New Whiskey, Brandy, or like Alcoholic Liquors.* J. F. Gallogly, Dublin. Eng. Pat. 15,568, October 4, 1889. 4d.

THE "maturing" of the spirit is effected by inserting through the bung-hole or other opening of the containing vessel a prepared rod of charcoal or carbon. The carbon rod may be of any suitable size and shape, and is so arranged that its lower end dips into the alcoholic liquid. The rods are prepared by moulding and heating vegetable or animal charcoal, or a mixture of the two. Or a rod of oak, converted into charcoal and freed from noxious substances by some suitable treatment, may be employed. The rod of charcoal absorbs the deleterious substances from the spirit, and by bringing them into contact with the condensed oxygen in its pores, effects their conversion into wholesome flavouring bodies. For the further "mellowing" of the spirit the inventor immerses the containing vessel, either wholly or partially under water, the term "wet storage" being applied to this portion of the invention.

—H. T. P.

*An Improved Cooling Apparatus for Brewing and Domestic Purposes.* C. Huelser, London. From N. Reif, Hanover, Germany. Eng. Pat. 16,079, October 12, 1889. 8d.

THE object of this invention is to effect rapid cooling with comparatively little water. For this purpose a cylindrical mashing tub is surrounded by a circular porous cooling water reservoir, the outer mantle of which is corrugated in order to increase its surface. This mantle is perforated, and a second smaller cylinder, also perforated, is placed between the tub and the reservoir, the intervening spaces being packed with wood-flock or other fibrous or porous material.

The whole arrangement is surrounded at some distance by an outer casing in which a greater or less degree of rarefaction can be maintained by means of a ventilator. The rate of evaporation of the water passing through the porous reservoir is thus accelerated. The moist atmosphere removed by aspiration is forced into a box where a portion of the water condenses and is returned to the reservoir. The remainder of the moist air is diffused through a fan-shaped opening over the surface of the liquid in the tub, thus leading to further cooling. The cooler for domestic purposes is similar in principle to the above apparatus.

—H. T. P.

*An Improvement in the Manufacture of Beer.* H. T. Brown and G. H. Morris, Burton-on-Trent, and E. R. Moritz, London. Eng. Pat. 19,003, November 26, 1889. 6d.

MALT worts contain a greater or less proportion of substances called amyloins. Amyloins are unfermentable during the primary stage of wort fermentation, but are slowly decomposed during the secondary fermentation in cask. Amyloins are rapidly converted into maltose under the influence of diastase. When unfermented, the amyloins are mainly the source of the palate-fulness of beer; afterwards it is to the result of their fermentation that the "condition" or briskness of beer is due. The object of this invention is to ensure the presence of amyloins in beer in such proportion as may be most suitable to obtain the required palate-fulness and condition. If the wort be deficient in amyloins a sufficient quantity may be at once added. In presence of excess of amyloins diastase is added in order to destroy them; afterwards the correct proportion of amyloins is restored to the wort. The method for the estimation of amyloins, given in this Journal, 1890, 533—535, usually suffices, according to the patentee. A wort should contain about 12—20 per cent. of amyloins, reckoned on the wort solids before fermentation. Amyloins may be added to the beer after primary fermentation, alone, or along with other brewing sugars, and with or without cold-water malt extract, according as to whether a rapid or slow secondary fermentation is desired.

Amyloins may be prepared in the following manner: 100 parts of starch, 300 parts of water, and 3 parts of sulphuric acid are boiled together until the product has a specific rotatory power of about  $193^\circ$ , and a copper oxide redning power of about 21, the cold sample giving at the same time a full red colour with iodine solution. At this stage the boiling is discontinued, and the liquid neutralised. The liquid should be filtered and concentrated. By varying the proportions of the materials, and the conditions as to time or temperature under which the reaction takes place, various amyloins may be produced.—H. T. P.

*Improvements in Maturing Spirits and other Liquors and Apparatus connected therewith.* J. McKinless, Manchester. Eng. Pat. 4108, March 17, 1890. 8d.

This is for the purpose of maturing spirits by compressed air or oxygen, or a mixture of these. Two kinds of apparatus are described. The first consists of a closed cylinder, furnished with two or more perforated diaphragms, one near the top being of metal, with small holes about  $\frac{1}{4}$  inch diameter, and the others of wire gauze, with meshes about 30 to the inch. An air pipe communicates between the space between the diaphragms and the top of the vessel, so that as the liquid runs down the air may pass up.

The liquor to be treated is run into the vessels, the pressure of air within increased by about  $\frac{1}{2}$  atmosphere and the liquid drawn off at the bottom and passed in again at the top by a pump, whence it falls through the vessel, being divided into a fine spray by the diaphragms. This is repeated until the spirit is properly matured by the oxidation.

In the second form of apparatus, the circulation of the liquid, instead of being effected by a pump, is brought about by inverting the vessel at intervals.—A. L. S.

*An Improved Means of Applying certain Antiseptic Agents to Beer, Wine, or other Fermented Drinks.* A. Boake and P. G. A. Roberts, Stratford. Eng. Pat. 10,845, July 12, 1890. 4d.

The antiseptics are weighed out in convenient amounts, mixed with about 5 per cent. of inert gummy matter, and compressed in moulds, so that they become a coherent mass when the pressure is withdrawn. The tablets may be conveniently  $\frac{1}{8}$  oz. in weight.—A. L. S.

*Improvements in "Pasteurising" Apparatus.* A. Regel, Schöningen, Germany. Eng. Pat. 11,249, July 18, 1890. 8d.

The apparatus consists of two closed cylinders whose lower ends are connected by unions with a pipe, which serves to convey the beer to be pasteurised from the cask to the apparatus. The cylinders are jacketed outside, and each is provided with an air-tight piston, operated by compressed air. A thermometer passes through each piston so that the temperature of the space beneath it can be determined. The top of each cylinder is fitted with a glass dome, into which the thermometer fixed in the piston can enter, so that its scale can be observed from the outside. Further, each cylinder carries at top a pressure gauge and a tap for the entrance of compressed air. The beer to be pasteurised is forced in at the bottom of the first cylinder by means of air pressure. The entrance of the liquid causes the piston to rise, and the moment when the latter reaches its highest point is indicated by an electric alarm, operated by the piston itself. The beer is now heated to  $82^\circ$  C. by passing steam through the outer jacket of the cylinder. As soon as the beer has reached the required temperature, it is transferred to the second cylinder by forcing air into the top of the first cylinder, thus causing its piston to descend. The beer is rapidly cooled to  $5^\circ$  C. in the second cylinder by passing warm water and then ice-cold water through the outer jacket. The beer is subsequently forced by means of compressed air through a froth-preventing device, and from thence through a draw-off cock and pipe into bottles or casks.—H. T. P.

*Improvements in the Manufacture of Wine and in Apparatus therefor.* G. F. Redfern, London. From G. Perscheid, Jersey City, U.S.A. Eng. Pat. 13,257, August 22, 1890. 6d.

This is for the purpose of manufacturing effervescent wine in bulk, allowing the wine to stand until clear and then bottling the clear wine without loss of carbonic acid. The wine is fermented in a wooden vat, the bottom of which is furnished with a number of hollows to retain the lees. The vat is contained in an air-tight receiver capable of resisting considerable pressure. The wine in fermenting evolves carbonic acid, which raises the pressure within the receiver; if the pressure becomes too great, the excess of gas is allowed to escape into a separate reservoir. When the fermentation is complete, the wine is cooled by an ice jacket, and allowed to stand 12 hours in order that it may become clear; it is then led through a filter into the bottles to contain it, a second pipe from the receiver leading the carbonic acid to the bottles, and the bottling is conducted as usual with aerated water.—A. L. S.

*Improvements in Apparatus for Cooling and Aërating Wort in the Manufacture of Malt Liquors.* H. H. Lake, London. From the Hanford-Stanford Company, Portland, U.S.A. Eng. Pat. 13,428, August 26, 1890. 8d.

This describes improvements in the apparatus described in Eng. Pat. 4982 (this Journal, 1890, 960); these are:—

1. An arrangement whereby the spray is thrown over only half or a quarter the area of a circle, over the centre of which the apparatus is situated. This is done by continuing the walls of the vertical tube downwards along half or three-quarters of its circumference; so that along this part no annular slit is formed when the conical deflector is

pulled down. Thus it is possible to arrange the spray producers over the edges of the cooler and have the wort thrown so that it may all fall into the cooler.

2. The conical deflector is furnished with a shoulder, so that the film of wort, as it issues through the annular opening, is deflected upwards and outwards, thus producing a more perfect spray and a more rapid cooling.

3. The cords connected with the levers to which the conical deflectors are attached are all brought to a common axle which may be moved by a lever, thus causing the deflectors to move away from the ends of the tubes and produce a simultaneous flushing. The axle is furnished with an arrangement, whereby the cords controlling the deflectors may be separately adjusted. Detailed drawings of the apparatus accompany the specification.—A. L. S.

## XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

### (A.)—CHEMISTRY OF FOOD.

*On the Phenomenon of Coagulation.* A. Béchamp. Bull. Soc. Chim. [3], 4, 181—186.

See under XXIII., page 1073.

*Report on Cocoa.* Report of the Central Laboratory of the Italian Customs Department, 288—289.

A DESCRIPTION is given of certain samples sent to the laboratory. It was decided to class a sample declared as cocoa powder, resembling the products found in commerce as soluble cocoa of Van Houten, &c., as "cocoa in powder or paste" and not as "chocolate." Certain samples were found to be sweetened, not with sugar, but with saccharine, though the importation of saccharine and products containing saccharine is strictly prohibited by Royal Decree No. 6407 (Series 3), September 29, 1889 (Journal, 9, 831). An exception is, however, made in the case of pharmaceutical products by Ministerial Decree No. 6416 (Series 3), October 5, 1889.—V. H. V.

### PATENT.

*A New or Improved Process and Apparatus for Preserving Organic Substances, and especially Alimentary Substances.* C. L. Bachelerie, Paris, France. Eng. Pat. 13,089, August 20, 1890. 8d.

THE articles—carcases of animals, poultry, fish, eggs, vegetables, &c.—are exposed, under a pressure varying with their size, to the carbonic anhydride and spray of hydrochloric acid evolved by the sudden addition of the desired quantity of hydrochloric acid to the requisite amount of sodium hydrogen carbonate.

The invention includes the design for a chamber capable of resisting the pressure, and fitted with movable supports for the material or articles, with arrangements:—for tipping the hydrochloric acid all at once on to the carbonate, for charging the chamber, for washing out the products, and for discharging them and also provided with the requisite safety-valves, indicators, &c.—D. A. L.

### (B.)—SANITARY CHEMISTRY.

*Purification of Waste Water from Sugar Refineries, &c.* H. Schreib. Chem. Zeit. 14, 1323—1324.

See under XVI., page 1053.

*On the alleged Sterilisation of River Water by Mine Water.* A. A. Breneman. J. Amer. Chem. Soc. 12, 12—15.

DURING an epidemic of typhoid fever which occurred in the city of Wilkesbarre in 1889, questions arose as to the purity of the different sources of water upon which the city depended, and the author was called upon to examine the waters. It was found that the supply from the Susquehanna river was preferred by the public and by local physicians in spite of the fact that it receives above Wilkesbarre the sewage of nearly 100,000 people in the course of 10 miles. It was believed by the people of Wilkesbarre that the river water was peculiarly free from possibility of transmitting infectious diseases because of the considerable quantities of mine water which it receives, the mine water being supposed to exert a sterilising effect through its well-known constituents, free sulphuric acid and sulphates of iron, but the results of the examination of the waters were sufficient to dispel this fancied security. Samples of water were taken:—1. From the Susquehanna river at the intake of the Wilkesbarre Water Co. 2. From the mouth of the shaft of the Hollenbach coal mine, the drainage from which runs into the river above Wilkesbarre. 3. (For comparison only) from the Hazleton coal mine at a depth of 300 feet from the surface.

### RESULTS OF CHEMICAL EXAMINATION.

	Grains per Gallon.					
	Total SO <sub>3</sub>	Free H <sub>2</sub> SO <sub>4</sub>	Fe <sub>2</sub> O <sub>3</sub>	CaO	MgO	SiO <sub>2</sub>
River .....	1.00	.00	.71	1.88	.16	..
Hollenbach mine	51.16	15.59	12.23	8.21	4.00	2.50
Hazleton mine...	127.30	20.85	65.40	2.55	4.27	2.70

The river water was alkaline in reaction and contained no iron in solution, the portion present being suspended ferric oxide. These data alone dispel the idea that the river water can retain at Wilkesbarre any of the germicidal power that may be possible to salts of iron or free sulphuric acid, whilst the effect of any inflow from the mines is shown to be insignificant. Fresh samples of the waters 1 and 2 were taken in sterilised bottles for bacteriological examination. The river water was found to contain 400 to 500 germs per cc. of at least 14 different species, six of these being of species that liquefy gelatin (putrefactive bacteria), and after sterilisation by discontinuous heating, the water was found capable of supporting the growth of true typhoid bacillus introduced by inoculation. The growth of typhoid bacillus was also possible in No. 2 after sterilisation, but not in No. 3. It is evident from these results that no effective sterilisation of the water of any large stream can result from the small and varying contributions made to its volume by mine drainage, and even mine waters of considerable strength, and undiluted, cannot be relied upon for certain effect against the high resisting power that the typhoid bacillus is known to possess.

It is certain, moreover, that a water rich enough in sulphuric acid or iron salts to act as a disinfectant would be entirely unsuited for drinking.—G. H. B.

### PATENTS.

*Improvements in and relating to Apparatus for Handling and Treating Sewage.* W. S. West, New York, U.S.A. Eng. Pat. 8239, May 27, 1890. 8d.

THE invention consists of arranging a pumping station for distributing sewage from sewers on to filter beds or elsewhere in such a manner that paper, insoluble matters and grease are intercepted and good ventilation is provided. The sewage enters the underground portions of the building, the discharge being regulated by gate-valves, and passes on to screens constructed of boards and framework filled in with sawdust or other suitable combustible material, and

supported on beams. Paper, grease, &c., are retained by this screening material, which is from time to time cleared out and burnt; whilst the liquid portions run on to the inclined floor in a chamber below, and collect in a tank in which suction pumps work. For ventilation the chimneys from the boilers are enclosed together in one external wall, leaving an intervening air space all round them, extending from the bottom to the top of the chimney; this air space connects with the underground chambers and with the sewage inlet pipes, and at a suitable height up also with the main chimney by openings in the wall, so that noxious fumes may not only be drawn up but portion of them also consumed. Suitable ducts are provided for conducting fresh air down into the underground chambers both above and below the screening floor. The invention includes an arrangement for preventing clogging at the connexion of the house with the sewer pipe and a pan for reducing grease, obtained from the sewage, by means of waste heat.

—D. A. L.

*Improvements in and relating to Preserving Compounds for Embalming Purposes.* W. P. Thompson, Liverpool. From J. R. Bate, F. W. Owen, and J. W. Simcock, Detroit, U.S.A. Eng. Pat. 13,046, August 19, 1890. 4d.

THE body to be preserved is placed, without any preliminary preparation, not even removal of clothes if human, in a chamber and exposed to fumes produced by the combustion of a mixture containing:—three parts of sulphur, three parts of charcoal, two parts of borax, two parts of sodium chloride, and two parts of calcium chloride all powdered and dry.

According to the patentees, “a chemical union takes place between the fumes or gases thus produced and the liquids of the body, producing acids which arrest present and prevent future decomposition.”—D. A. L.

## (C)—DISINFECTANTS.

## PATENTS.

*An Improved Means of Applying Certain Antiseptic Agents to Beer, Wine, or other Fermented Drinks.* A. Boake and F. G. A. Roberts, Stratford. Eng. Pat. 10,845, July 12, 1890. 4d.

See under XVII., page 1057.

*The Manufacture and Production of a New Antiseptic.* J. Y. Johnson, London. From E. Salomon, Paris, France. Eng. Pat. 13,488, August 27, 1890. 4d.

To produce a non-poisonous but powerful antiseptic a solution containing from 1 gm. to 0.5 gm. of mercuric chloride per litre is mixed with 8 to 10 per cent. of sodium chloride, and with a variable proportion of a sulphate such as zinc, copper, or best of all cadmium sulphate, tartaric acid may also be added. The accessory constituents are intended to contribute emetic properties and prevent poisoning by absorption.—D. A. L.

## XIX.—PAPER, PASTEBOARD, Etc.

*On the Qualitative Determination of Mechanical Wood-Pulp in Paper.* W. Herzberg. Mitt. Königl. tech. Versuchs. 1890, 132—140.

See under XXIII., page 1068.

*On the Quality of Certain Hand-Made Papers.* W. Herzberg. Mitt. Königl. tech. Versuchs. 1890, 141—143.

DIFFERENCES which occur in the tearing length and elongation at fracture in testing the same paper, originate partly in inequalities of the paper itself, partly in the changes of temperature and moisture of the testing room, and partly in the apparatus used for the tests (see Mitt. Königl. tech. Versuchs. 1887, 36, and 1888, 78). A series of seven different hand-made papers tested at the beginning, in the middle, and at the end of the manufacturing process, gives some further information on this subject. The tests were made with Wendler's apparatus, strips of 180 × 5 mm. being torn in both directions (five across and five along the web) for each test. No regular changes of the tearing length and elongation at fracture have been found in comparing the three mentioned stages of manufacture, and the variations are comparatively small. The maximum differences were found in the two following tests:—

Stages in Manufacture.	Ash.	Weight.	Tearing Length.			Elongation at Fracture.			Difference from Total Mean.		Temperature of Testing Room.	Moisture of Testing Room.
			Along Web.	Across Web.	Mean.	Along Web.	Across Web.	Mean.	Tearing Length.	Elongation at Fracture.		

## I.—LINEN FIBRES, WOOD CELLULOSE, AND COTTON FIBRES.

End.....	6.8	383	3.04	2.74	2.89	3.6	3.7	3.7	+17.48	+8.8	16.2	56

No satisfactory explanation is given for the remarkable change of percentage of ash in the second sample, no similar differences being found in any other cases of the whole series. The manufacturer tried to account for it by

suggesting the paper had been improperly treated with china clay, but admitted that a mistake in the manufacture is not impossible.—H. S.

## PATENTS.

*Improvements in the Process of Manufacturing Thin Sheets of Nitro-Cellulose.* E. N. Todd, Newark, New Jersey, U.S.A. Eng. Pat. 9315, June 16, 1890. 8d.

NITRO-CELLULOSE is dissolved in a mixture of acetate of methyl, acetate of amyl, fusel oil, and oil of camphor, with or without the addition of solid camphor. Glass plates are suspended from the top in a vessel fitted with a cover and provided at the bottom with a valve. The glass plates being in position the solution of nitro-cellulose is run in. After remaining some time to allow the escape of air bubbles the solution is slowly run off, leaving a thin layer on the glass plates which quickly dries as a thin film of transparent celluloid. When thoroughly dry the films are stripped from the sheets of glass and the latter are transferred again to the vessel.—E. J. B.

*Improvements in the Preparation or Treatment of Paper for Copying Letters, Documents, and the like, including such as are done with a Type-Writing Machine, and Improvements in Chemical Compounds or Preparations therefor.* W. Rogers, Liverpool. Eng. Pat. 12,139, August 2, 1890. 4d.

For press-copying type-writing the inventor used a mixture of 9 parts of methylated spirit and 1 part of glycerin instead of water. When type-writing and ordinary writing are to be copied at the same time he used a mixture of the above solution with what is known as Roger's Copying Preparation (Eng. Pat. 14,274 of 1886), together with the addition of one or other of the following chemicals: oxalate of potassium or sodium, sulphide of ammonium, vanadate of ammonium, chromate or bichromate of potassium, ferri- or ferrocyanide of potassium, galle, pyrogallie or tannic acid.—E. J. B.

## XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

*Iso- and Allo-Cinnamic Acid.* C. Liebermann. Ber. 23, 2510—2516.

ISO-CINNAMIC acid has been found to be associated with another acid, to which the name of *allo-cinnamic acid* is given, in the acid liquors obtained as a by-product in the manufacture of cocaine, after the removal of the insoluble acids (this Journal, 1890, 541). The two acids resemble each other closely, but differ in their crystalline form, melting point, and solubility in petroleum spirit. This solvent was employed for separating them, *allo-cinnamic acid* being the less soluble. Analyses of the new acid agree with the formula  $C_9H_8O_2$ , i.e., with its being an isomer of cinnamic acid. It melts at  $68^\circ$  (*iso-cinnamic acid* melts at  $57^\circ$ ) and crystallises in the monoclinic system.

Several of the salts and properties of the new acid are described and compared with the corresponding ones of the *iso*-compound.—C. A. K.

### *Theoretical Considerations on the Truxillie Acids.*

C. Liebermann. Ber. 23, 2516—2518.

FOUR truxillie acids (di-cinnamic acids) have been described by the author, all of which he regards as derivatives of tetramethylene.

The formation of cinnamic acid by the distillation of the truxillie acids is also regarded as being a proof of their being derived from tetramethylene.—C. A. K.

*The Oxidation of Ecgonine.* C. Liebermann. Ber. 23, 2518—2522.

EINHORN has pointed out (this Journal 1890, 890) the near relationship existing between tropidine and ecgonine, since anhydro-ecgonine is decomposed by heating with hydrochloric acid to  $280^\circ$  with formation of tropidine.

Should this constitution for anhydro-ecgonine be correct, then the author regards it as probable that ecgonine itself is tropin-carboxylic acid, with the carboxyl group in the side chain, in which case both anhydro-ecgonine and ecgonine should yield when oxidised under like conditions the same oxidation products. The author has studied the oxidation products of ecgonine by means of chromic acid, following Merling's directions.—C. A. K.

*The Formation of Lepidine Derivatives from Quinine and Cinchene.* W. Koenigs. Ber. 23, 2669—2679.

COMSTOCK and Koenigs (this Journal, 1885, 64) have shown the relationship of quinine and conquinine  $C_{20}H_{22}N_2O_2$  to quinine  $C_{20}H_{22}N_2O_2$ , and of cinehonine and cinechonidine  $C_{19}H_{20}N_2O$  to cinchene  $C_{19}H_{20}N_2$ .

Quinine, cinehonine, and cinchene are now studied by the author, and further derivatives are prepared.

Since cinechonine is decomposed by concentrated alkali with the formation of both quinoline and lepidine it would be expected that quinine would yield para-methoxylepidine in conjunction with the para-methoxyquinoline which is known to be formed under the same conditions. In fact Krakau (this Journal, 1885, 688) has shown that when the cinchona alkaloids are heated with caustic potash to  $200^\circ$  in a current of superheated steam a base is formed whose hydrate melts at  $52^\circ$ . The author has repeated this experiment and finds the base to be para-methoxylepidine, identical in all its properties with the base obtained from quinine.

It is found not improbable that the carbon atoms attached to the quinoline residue in quinine and cinchene are doubly linked, thus:  $-C_9H_6N-CH=CH-$  and that in quinine and cinechonine these carbon atoms are attached both to a hydrogen atom and to a hydroxyl group, which would account for the greater difficulty with which they are decomposed when compared with their "anhydro bases," quinine and cinchene (see also this Journal, 1887, 146 and 736.)—C. A. K.

*Substitution Products of Lepidine.* A. Busch and W. Koenigs. Ber. 23, 2679—2688.

THE following derivatives of lepidine have been prepared:—*Para-lepidine sulphonic acid*, *Benzylidene-lepidine sulphonic acid*, *Para-hydroxylepidine*, and *Para-amido-lepidine*.

Lepidine is treated with a mixture of fuming nitric and sulphuric acids in the cold, and the nitro-compound formed, crystallised from hot alcohol. It is colourless and melts at  $126^\circ$ — $127^\circ$ . Other products appear to be formed in the reaction.—C. A. K.

*Crystalline Veratrine.* F. B. Ahrens. Ber. 23, 2700—2707.

THE material for the following experiments was obtained from Merck of Darmstadt, the identity of the veratrine itself being established by an analysis of its gold double chloride, which gave values corresponding with the formula  $C_{32}H_{49}NO_9 \cdot HCl \cdot AuCl_3$ . The double salt, when dried at  $100^\circ$ , melts, with decomposition, at  $182^\circ$ . The mercuric chloride double salt can also be obtained crystalline from alcoholic solution. It melts and decomposes at  $172^\circ$ . When an aqueous solution of picric acid is added to an alcoholic solution of veratrine hydrochloride, crystals of the picrate separate on standing. These are very stable, and only begin to decompose at  $228^\circ$ . All these salts are very difficultly soluble in water and fairly readily soluble in alcohol.

With platinum chloride, veratrine hydrochloride forms an amorphous precipitate, which dissolves in alcohol, but is decomposed by water.

Veratrine, when treated with bromine water, readily takes up 4 molecules of the halogen, to form a tetra-brom-addition product,  $C_{25}H_{49}NO_5Br_4$ , an amorphous yellow powder insoluble in water, soluble in alcohol, ether, &c. This body is easily decomposed by dilute alkali to form a dibromo-addition product,  $C_{25}H_{49}NO_5Br_2$ , also an amorphous body. Substitution products appear also to be formed when veratrine is treated with bromine, but were not isolated. Aqueous caustic potash, baryta water, ammonia, and even water in a closed tube at  $200^\circ$ , all decompose veratrine more or less completely into angelic acid,  $C_5H_8O_3$ , and a base which appears to have the composition  $C_{25}H_{45}NO_3$ . The latter is probably identical with the so-called "cevin," and differs very little from "ceirdine," the bases obtained by Wright and Luff and by Bosetti respectively, in decomposing veratrine by means of alkali.

By heating veratrine with concentrated hydrochloric acid, tiglic acid,  $CH_3 - CH = C.(CH_3).CO.OH$ , is obtained, together with a basic substance of unknown composition. Oxidising agents act very energetically upon the alkaloid; nitric acid decomposes it completely. With potassium permanganate, acetic and oxalic acids result, whilst chromic acid yields carbon dioxide and acetaldehyde. When subjected to dry distillation, tiglic acid and  $\beta$ -picoline are formed, whilst when heated with lime  $\beta$ -picolin, a secondary base,  $\beta$ -pipercoline,  $C_6H_{13}N$ , and iso-butane appear to result.—C. A. K.

#### On Strychnine. J. Tafel. Ber. 23, 2731—2739.

TWENTY years ago Stahl Schmidt found (Pogg. Ann. 108, 513) that methyl iodide forms with strychnine an addition product from which may be obtained the base methyl-strychnine. The author has undertaken an examination of this compound and of its further derivatives, with a view to ascertaining the constitution of strychnine. The strychnine-methyl iodide Stahl Schmidt looked upon as a hydriodide, viz.,  $C_{23}H_{29}N_2O_3.IH$ , although it is unacted on by potash. Strychnine-methyl iodide has the true character of an ammonium iodide, it possesses a neutral reaction, and gives, in aqueous solution with silver oxide, an alkaline base. This base, when neutralised with hydriodic acid, gives the methyl iodide again. It is, without doubt, the ammonium hydroxide corresponding to the strychnine-methyl iodide.

By molecular change from this ammonium base, methyl-strychnine is obtained.

Methyl-strychnine unites at ordinary temperatures with methyl iodide, forming a methyl iodide,  $C_{23}H_{29}N_2O_3.I$ , which with silver oxide gives an alkaline substance, but as secondary product a beautifully crystalline neutral body of the formula  $C_{23}H_{28}N_2O_3$ . This the author calls dimethyl-strychnine. It forms salts, which monomethyl-strychnine does not do.

Dimethyl-strychnine further unites with methyl iodide, giving a product of the composition  $C_{24}H_{31}N_2O_3.I$ . This product is a true methyl iodide, giving an alkaline basic substance on treatment with silver oxide; all attempts at isolation proved fruitless, however, strychnine itself being always re-formed—

The author has also undertaken an examination of the hydrate of strychnine.

Gal and Etard (Bull. Soc. Chim. 31, 98) obtained a compound,  $C_{21}H_{26}N_2O_4$ , by heating strychnine with baryta water in a closed tube at  $130^\circ$ — $140^\circ$ ; this compound they called dihydro-strychnine. Loebisch and Schoop (Monatsh. 7, 83), by the action of alcoholic sodium hydrate on strychnine, obtained a compound which they called "strychnol." This, from the present memoir, appears to differ from the preceding compound by the elements of water. Hence, the former substance is termed here strychnine dihydrate, the latter strychnine monohydrate.

The soda salt of strychnine dihydrate by the action of methyl iodide gives the methyl iodide of a tetramethyl-strychnine dihydrate.—T. L. B.

#### Tropidine. A. Einhorn. Ber. 23, 2889—2894.

TROPIDINE, when treated with an aqueous solution of hypochlorous acid, yields two products, which can be separated by virtue of their different solubilities in a mixture of alcohol (2 parts) and water (3 parts). The more soluble of these melts at  $108^\circ$ — $109^\circ$ , and appears to have the composition  $C_5H_{13}N(HClO)_2$ . The less soluble body was only obtained in small quantity, and no analysis is given; it melts at  $138^\circ$ . Further investigations on the decomposition products of this body are delayed by the author, owing to the publication of Ladenburg's work on allied subjects (Ber. 23, 1780 and 2225).—C. A. K.

#### Contribution to the Knowledge of Papaveroline. K. Krauss. Monatsh. 11, 350—362.

PAPAYEROLINE is prepared by heating 30 grms. of papaverine and 250 grms. of hydriodic acid (sp. gr. 1.96) for 10—11 hours. On cooling, the hydriodide of the base crystallises out, and is purified by recrystallisation from water. The free base is obtained by adding a solution of sodium bicarbonate saturated with carbon dioxide to a cold saturated solution of the hydriodide. The base is precipitated as a white crystalline powder. It has a composition expressed by the formula  $C_{16}H_{13}NO_4.2H_2O$ . It contains four hydroxyl groups and is consequently a very feeble base, being precipitated from solutions of its salts by sodium acetate.

The base is easily soluble in dilute mineral acids and oxalic acid and also in acetic acid and glycerol, even if somewhat dilute. It is fairly easily soluble in alcohol, especially in warming. It is but slightly soluble in ether and chloroform and insoluble in benzene, petroleum spirit, and water. A weak alcoholic solution gives a fine blue colouration with a little potash, and with an excess of the latter a dark reddish-violet colouration; addition of hydrochloric acid causes the colour to become brown and potash again converts this into blue.

The author has also investigated the products of the distillation of the base with zinc; he obtained  $\alpha$ -methyl-isquinoline and another base which he was not able to identify with certainty.—A. L. S.

#### A Double Salt of Cocaine. W. Müller. Pharm. Zeit. 35, 522.

On mixing fairly concentrated solutions of mercuric chloride and cocaine hydrochloride, the double salt  $C_{17}H_{19}NO_4.HgCl_2.2H_2O$  separates as a bulky precipitate, having a fine crystalline appearance after washing, and drying in the desiccator. It melts at  $124^\circ$  C. to a clear colourless liquid, which solidifies on cooling to an opaque mass. It has a distinct metallic taste characteristic of mercury compounds, perceptible in spite of the anæsthetic action of the cocaine on the tongue.—B. B.

#### The Preparation and Properties of Aricine. H. Moissan and E. Landrin. Bull. Soc. Chim. [3], 4, 257—260.

ARICINE was first prepared and described by Pelletier and Coriol, who obtained it from a bark bearing the name of "Quinquina de Cusco" or "Arica bark." Since then the alkaloid has been examined by various observers. The bark employed by the authors was of a grey colour externally and reddish inside. It contained neither quinine nor cinchonine, and was particularly rich in aricine, of which it contained 3—3.5 per cent. The method adopted for extracting the alkaloid was as follows.—One kilo. of the coarsely powdered bark is mixed with 100 grms. of lime and 100 grms. of soda lye at  $40^\circ$ , the mixture being evaporated almost to dryness on the water-bath. The residue is continuously shaken for half an hour with 4 litres of ether. The ether is decanted and shaken for a short time with 100 grms. of sulphuric acid (1 in 10) and 60 cc. of water. Insoluble aricine sulphate separates as a yellowish cheesy mass. The ether is decanted, being employed to extract a further quantity of alkaloid from the bark. The ethereal extract is treated with sulphuric acid as before, and so on, the operation being repeated about six times. The aricine

sulphate is separated from the united acid liquids by filtration. The clear filtrate gives with caustic soda a precipitate of an uncrystallisable alkaloid which will be referred to at some future time. To obtain the arietine in a state of purity, 150 grms. of the crude sulphate are dissolved in 5 litres of boiling water, and ammonia is added until the base is completely precipitated. 115 grms. of a viscous mass are thus obtained which solidifies on cooling to a friable substance resembling resin. The precipitate is powdered and dissolved in boiling alcohol at the rate of 100 grms. per litre. On cooling the arietine crystallises out. The operation is repeated until the crystals are colourless.

Arietine forms beautiful transparent crystals, 5—8 mm. in length, which on exposure to sunlight assume after some time a slight yellow tinge. If the crystals be not quite pure the colouration is rapidly produced. Arietine is insoluble in water; at 15° C., one litre of alcohol dissolves 10 grms. and at the boiling point, 90 grms. Ether takes up 30 grms. per litre at 15° C. Arietine melts at 188°—189° C. Its specific rotatory power in alcoholic solution (alcohol of 95 per cent.) was found to be  $(\alpha)_D = -58.18'$  at 16.6° C., the solution containing about 0.8 gm. per 100 cc. In alcoholic hydrochloric acid solution arietine has the specific rotatory power  $(\alpha)_D = -14.30'$ .

The melting point and optical activity serve to differentiate arietine from euscimine, with which it is isomeric.—H. T. P.

*The Manufacture of Commercial Hydrogen Dioxide and its Applications.* A. Bourgongnon. J. Amer. Chem. Soc. 12, 64—69.

THE author describes the following method for the production of hydrogen peroxide on a commercial scale. The first step, and a very important one, is the hydration of the barium peroxide, which is effected by pouring the powdered substance into a cylindrical stone pot half full of water, and stirring the mixture with a wooden spatula occasionally during three or four hours, when the barium peroxide forms a thick, perfectly white and smooth, pasty mass resembling white clay mixed with water. While the hydration is progressing, a mixture of water and hydrofluoric acid is made in a vessel lined with sheet lead and surrounded with ice water so as to keep the temperature of the acid mixture below 10° C. The hydrated barium peroxide is then added in portions of three to four pounds at a time to the acid mixture, stirring all the time to mix the contents of the vessel thoroughly. All the barium is transferred to the acidulated water in about two hours, and the agitation continued for four hours. If the operation has been well conducted all the barium peroxide is transformed into fluoride, which falls to the bottom of the vessel. When this precipitate is well settled the supernatant liquid is decanted into a vessel similar to the one used for its production, and also surrounded by ice-water. The clear liquid contains an excess of acid and impurities derived from the materials employed, consisting chiefly of ferric oxide, alumina, and manganese oxide, which must be removed to insure the keeping properties of the product. To this end small quantities of hydrated barium peroxide are added with stirring to the cold solution until the last traces of acid are saturated, when the appearance of the solution suddenly changes from a bright yellow to a greyish colour, and the impurities separate and collect at the surface of the liquid. Without losing time the liquid is filtered through a cheese cloth stretched on a frame, and received in a vessel which contains a small quantity of dilute sulphuric acid (one part acid to eight parts water). This filtration must be quickly done. As long as the solution is alkaline there is great danger of decomposition and loss of oxygen. If the liquid is thrown upon the filter the latter will be quickly clogged, the filtration stopped, and the hydrogen peroxide will rapidly decompose, emitting large bubbles of oxygen with a hissing noise; but as the precipitated impurities collect first on the top of the liquid the solution is syphoned from below these impurities, and it filters quickly and satisfactorily. The filtered liquid is tested for barium and sulphuric acid is added until all is removed. The liquid is left over night, the precipitate of barium sulphate settles,

and the perfectly clear and colourless solution is ready for the market. All the precipitates are separated by pressure from the liquid they contain, which is added to the water employed in the next operation. Nearly 40 gallons of hydrogen peroxide were produced at the following cost:—

	Dollars.
60 lb. barium peroxide at 25 cents ...	15.00
25 lb. hydrofluoric acid at 18 cents ...	4.50
Ice .....	0.50
	<hr/> 20.00

The method recommended by Thomsen consists in dissolving the barium dioxide in dilute nitric acid, whereby a large amount of the barium becomes precipitated as nitrate, from which barium peroxide can be recovered by ignition; the small quantity of barium remaining in solution is removed by addition of sulphuric acid. The barium peroxide may also be suspended in water and decomposed by a stream of carbonic acid, which produces a very pure solution of hydrogen peroxide, but too weak for industrial applications.—G. H. B.

*On the Preparation of Thiophen.* L. H. Friedburg. J. Amer. Chem. Soc. 12, 83—90.

THE author gives full details of the method of preparation of thiophen by Volhard and Erdmann's method (Ber. 18, 454) from sodium succinate and phosphorus trisulphide. The sodium succinate was prepared from succinic acid and sodium carbonate and dehydrated at 110°; the phosphorus trisulphide was got by heating the mixture of phosphorus and sulphur in a porcelain crucible, small portions being added at intervals after the first portion had been ignited.

To prepare the thiophen, 155 grms. of sodium succinate and 310 grms. of well crushed phosphorus trisulphide were distilled from a 3-litre tubulated retort, heated over the free flame. The distillate was redistilled from the water-bath, washed with sodium hydrate, dried over metallic sodium and redistilled. 150 grms. of pure thiophen were obtained from 610 grms. of sodium succinate and 1,200 grms. of phosphorus trisulphide. It was found advisable to prepare several lots of thiophen before subjecting them to the final purification, on account of the mechanical loss that takes place in the latter process.

The residue in the retort evolves sulphuretted hydrogen on the addition of water, and appears to contain either phosphorus acid or phosphites or both.—C. A. K.

*Is Saccharine Innocuous?* Chem. Zeit. Rep. 14, 189—207.

FAHLBERG, List and Co., publish from time to time the opinion of numerous authorities on this subject. One of the first medical men in Austria has stated that saccharine does not appear to be injurious either to healthy or to sick persons, even when administered in considerable quantities. Professors Javorsky and Rosenzweig have come to the conclusion that a daily dose of 100 grms. has no disturbing effect on the organs of sense, the nervous system, the circulation, or the respiratory or urinary organs. In the digestive organs any dose above 25 grms. per day causes irregularities. Larger doses produce diarrhoea, but less so than an equal weight of common salt would do. Acute diseases do not seem to be affected in any way by saccharine. It does not reduce the appetite. The saliva does not absorb it, but the urine contains almost the total quantity taken after about half an hour. The yearly consumption of the sodium salt of saccharine per head might be taken at 109—172 grms.; the action of this quantity on the functions of the body must be practically nil, and very small indeed on the digestive organs, much less so, at least, than the spices usually employed. In certain diseases, such as diabetes mellitus, obesity, cancer of the stomach, &c., the new sweetening agent is warmly recommended.—A. R.

*Report on Compounded Medicines, Gums, and Resins.*

Report of the Central Laboratory of the Italian Customs Department, 1886—1889, 352—356.

COMPOUNDED medicines are subject to a duty of 120 lire per quintal, and are defined in a note as follows: "Medicinal drugs mixed together or mixed with pulps, sugars, extracts, whether moist or dissolved with syrups, mucilages, spirits, &c., or when such mixtures are found in the form of powder or dried paste, or when they are soft or in the liquid state. Among compounded medicines shall likewise be reckoned artificial balsams and effervescent citrates of magnesia and lithia.

The following cases, among others, are specially cited: A liquid declared as "sweetened spirit" was found to contain besides alcohol and sugar, a considerable quantity of extract of quinine and quassia, coloured brown with caramel and flavoured with orange essence. It was classified under the title in the tariff report "of stomachic and pharmaceutical elixirs of every sort." A sample declared as chrome iron-stone was found to be nothing but reduced iron, which is specially mentioned in the report.

In the case of sulphonal a Ministerial decree decided (October 28, 1888) that this substance is to be classed with chloral hydrate under the category of "compounded medicines not specified" (with alcohol as a basis). Ichthyol and its preparations were classed by a decree (December 13, 1888) in the same category; similar decrees were issued regarding malt extract (Gesundheits-bier) and pepsin with hydrochloric acid (April 6, 1889).—V. H. V.

*Report on Perfumery.* Report of the Central Laboratory of the Italian Customs Department, 366—367.

IN the tariff report perfumery is classed as alcoholic and non-alcoholic, the former paying, besides the tax of 100 lire per quintal, the surcharge on the alcohol contained therein. Among substances specially mentioned are a sample, declared as common soap, but recognised as a perfumed fat containing sandstone, another as fatty perfumery, recognised as alcoholic perfumery, containing brilliantine.—V. H. V.

## PATENTS.

*Improvements in the Treatment of the Disulphones for Medicinal Purposes.* G. Lunan, Edinburgh. Eng. Pat. 18,434, November 19, 1889. 4d.

THE disulphones (sulphonal, trional, tetranal, &c.) are dissolved in chloroform, ether, &c., and the dissolved drug separated in an amorphous condition either by precipitation with water or by evaporating off the solvent. The drugs thus prepared, or whilst still in solution, are acted on by an oleaginous solvent such as olive oil, castor oil, hydrocarbon oil, or jellies, whereby they are obtained in a more soluble form and one in which they possess an improved physiological action. This may be done enclosed in a flexible gelatin capsule or other suitable material.—C. A. K.

*Improvements in the Manufacture of Tetrachloride of Carbon.* W. H. Lever, J. D. Lever, and E. J. Scott, Port Sunlight. Eng. Pat. 18,990, November 26, 1889. 6d.

DRY chlorine is passed slowly and in a fine stream into carbon bisulphide, in which is dissolved from 2—12 per cent. of its weight of iodine, the following reaction taking place,  $\text{CS}_2 + 3 \text{Cl}_2 = \text{CCl}_4 + \text{S}_2\text{Cl}_2$ , the iodine acting as a carrier of chlorine. When the original volume of the carbon bisulphide has increased threefold the product is slowly distilled, the tetrachloride coming over first and the sulphur chloride remaining behind. The former is refractionated, washed with alkali, and redistilled. The iodine is recovered from the alkaline washings. Bromine and pentachloride of antimony can be substituted for the iodine, but are less efficacious.—C. A. K.

## XXII.—EXPLOSIVES, MATCHES, Etc.

*Determinations of the Firing Points of Various Explosives.* C. E. Munroe. J. Amer. Chem. Soc. 12, 57—64.

For this purpose an apparatus, devised by Horsley, was used, which consisted of an iron stand with a ring support holding a hemispherical iron vessel, in which paraffin or tin was put. Above this was another movable support, from which a thermometer was suspended and so adjusted that its bulb was immersed in molten material in the iron vessel. A thin copper cartridge case,  $\frac{3}{4}$  in. in diameter and  $1\frac{1}{8}$  in. long, was suspended over the bath by means of a triangle so that the end of the case was 1 in. below the surface of the liquid. On beginning the experiment, the material in the bath was heated to just above the melting point, the thermometer was inserted in it, and a minute quantity of the explosive was placed in the bottom of the cartridge case. The temperature marked by the thermometer was noted as the *initial temperature*, the cartridge case containing the explosive was inserted in the bath, and the temperature quickly raised until the explosive flashed off or exploded, when the temperature marked by the thermometer was again noted as the *firing point*. The tables given show the results of about six experiments with each explosive. The initial temperatures range from 65 to 280 °C. in some cases, but as the firing points remain fairly constant, only the extremes of the latter are quoted in the following table:—

Description of Explosive.	Firing Point in ° C.

## PATENTS.

*Improvements in or connected with Wax Matches.* P. Molyneux, London. Eng. Pat. 16,028, October 11, 1889. 4d.

THE material for the stems of the matches is made by forcing a mass of some fibrous pulp, such as Swedish wood pulp and paraffin mixed with a small quantity of stearin, and rendered plastic by heat, through a jet or orifice, whence it issues in the form of a long thin rod, which becomes hard on cooling, and is afterwards cut into suitable lengths and dipped in the usual way. Or the wood pulp may be rendered plastic by mixing it with one of the lighter petroleum spirits, and formed into a rod as before, and then passed through a bath of melted paraffin and stearin.—W. M.

*Improvements in Plant for Burning Special Charcoal for the Manufacture of Gunpowder.* J. S. Taylor and S. W. Challen, Birmingham. Eng. Pat. 16,426, October 18, 1889. 8d.

THE improvements consist in constructing the revolving drum, which contains the wood to be carbonised, and the lower part of which is in a furnace, with hollow trunnions, or with a hollow shaft which passes right through the centre of the drum, and which is perforated. The gases which are given off during the carbonisation of the wood escape by the hollow trunnions or shaft, and are led into the furnace, where they are consumed, and thus effect a saving in the main supply of fuel. The shaft is attached to the cylinder or drum in such a way that when the latter burns out it can easily be removed and a new one substituted for it.—W. M.

*Improvements in Plant for Preparing Gunpowder Carbon, consisting in the Application of Gaseous or Liquid Fuel to Heat the Carbonising Vessel.* J. S. Taylor and S. W. Challen, Birmingham. Eng. Pat. 16,629, October 22, 1889. 8d.

IN this patent "any ordinary well-known system of furnace suitable for burning liquid or gaseous fuel" is employed in conjunction with the patentee's improved method of supplementing the fuel by conducting the gases evolved from the material during its carbonisation (see Eng. Pat. 16,426, preceding abstract), into the fire chamber. Drawings accompany the specification.—W. M.

*An Apparatus for Nitrifying Cotton, Cellulose, Straw, and similar Material.* E. Müller, Cologne, Germany. Eng. Pat. 8843, June 7, 1890. 6d.

THE material is treated with acid in a vessel provided with a perforated false bottom. This vessel is kept cool by a water-jacket. A pipe leads from below the perforated bottom to an acid reservoir, which is in connexion with a vacuum pump. When the process of nitration is ended, communication is established between the vacuum pump, reservoir, and nitrating vessel; the acid is thus all removed from the cellulose, &c. by suction, and drawn into the reservoir, from whence it can be allowed to flow back into the nitrating vessel, after the material has been removed from it, for another operation.—W. M.

*Improvements in or appertaining to Explosive Compounds.* W. P. Thompson, Liverpool. From S. D. Smolianinoff, Washington, U.S.A. Eng. Pat. 11,018, July 15, 1890. 4d.

THE object of this invention is to render nitroglycerin insensitive to concussion.

AN alcohol, preferably methyl alcohol, is added to nitroglycerin in the proportion of one volume of alcohol to three volumes of nitroglycerin. The union is facilitated by slightly heating the nitroglycerin. Or one volume of "acetic ether of glycerin" is added to three volumes of nitroglycerin. The resulting compound may be mixed with the usual absorbents, and can be exploded by a fulminate.—W. M.

*Improved Vacuum Drying Apparatus for Explosive Substances.* H. J. Haddan, London. From J. H. Voelkel, Breslau, Germany. Eng. Pat. 11,745, July 26, 1890. 11d.

ACCORDING to this invention the explosive material is dried in vacuo. The apparatus consists essentially of a drying chamber and an expansion chamber which are in communication and from which the air is more or less exhausted. The drying chamber is provided with air-tight doors opening outwards, so that in the event of an explosion generating more gas than will fill the exhausted space, the pressure is at once relieved by these doors.

The apparatus is fully illustrated by drawings.—W. M.

## XXIII.—ANALYTICAL CHEMISTRY.

## APPARATUS.

*On the Determination of the Viscosity of Lubricating Oils.* A. Martens. Mitt. Königl. techn. Versuchs. 1890, 143—151.

See under XII., page 1042.

INORGANIC CHEMISTRY.—  
QUANTITATIVE.

*Determination of Alumina for Technical Purposes.* M. Kretzschmar. Chem. Zeit. 14, 1223.

THE determination of alumina by the usual gravimetric methods is wasteful of time on account of the tedious washing requisite. Attempts to use the volumetric process consisting in precipitating the alumina in acetic solution with a known quantity of sodium phosphate and titrating the excess of phosphoric acid by the ordinary uranium method, have not met with much success owing to the uncertainty of the point when excess of uranium is indicated by its reaction with potassium ferrocyanide, the perceptible solubility of alumina in ammonium salts, and the delay occasioned by the need for repeated titrations, which renders the rapidity of the process somewhat illusory.

By avoiding the use of ammonium salts altogether, adding sodium phosphate at once in excess and in the cold, and standardising the phosphate solution by means of an aluminium salt of known composition, the process becomes trustworthy.

175 grms. of uranium acetate (not nitrate) are dissolved and made up to five litres, and the exact strength of the solution determined by titration against sodium ammonium phosphate (14.718 grms. per litre), the purity of which has been ascertained by analysis; it is then diluted so that 1 cc. corresponds to about 0.004 grm. of  $P_2O_5$ . 10 grms. of pure potash alum, free from iron, are dissolved in water, sodium acetate and acetic acid added in excess, and the whole made up to 500 cc.; 50 cc. are taken, 10 cc. sodium acetate solution added, a known quantity of standard sodium phosphate solution added in excess, the mixture brought to the boil, and titrated with uranium solution. The titration is performed several times until the quantity requisite is so nearly known that the end point can be determined by the addition of only a few tenths of a cubic centimetre of the solution.

THE standard solution of alum cannot be taken as correct, as even the best and smallest crystals contain excess of water, but its exact content of alumina must be determined as follows: 50 cc. are precipitated by sodium phosphate in excess, followed by sodium acetate, the precipitate being then redissolved by hydrochloric acid. The solution is heated and reprecipitated by sodium thiosulphate in great excess, and boiled until it will settle, leaving the liquid clear; prolonged boiling is to be avoided. It is filtered,

washed with hot water, dried, ignited with free access of air, and weighed as aluminium phosphate. Its weight multiplied by 0.4204 gives that of the alumina present.

In order to avoid the tiresome repetitions of the titration with uranium acetate which are usually necessary, the quantity of alumina present in any given sample to be analysed may be approximately determined by adding to its solution a very little methyl-orange and titrating with caustic potash until the red colour disappears, showing that the free acid has been neutralised. Phenolphthalein is then added and the titration continued until a red colouration is produced; the difference between the first and second titrations gives the quantity of potash corresponding with the alumina present. The determination by means of the phosphate process described above can then be carried out in the ordinary way, one titration sufficing. As in analysis of most aluminium salts the free acid must be determined, no additional consumption of time results from the use of this plan. The application of the method to practical requirements is generally easy. In the case of an ammonia alum, caustic soda should be added and the bulk of the ammonia boiled off before titration. The analysis of an impure ferruginous sample of aluminium sulphate may be taken as an example of the working of the process: 5 grms. are dissolved and made up to 500 cc., the free acid determined by titrating 50 cc. with caustic potash, using methyl-orange as an indicator, and the approximate quantity of alumina by continuing the titration after the addition of phenolphthalein. Another portion of 50 cc. is heated with a few drops of hydrochloric acid containing bromine, sodium acetate added in excess, then a known quantity of sodium phosphate in excess, and the approximate quantity of alumina being known, the exact quantity of unprecipitated phosphate determined by a single titration with uranium acetate.

The total quantity of iron may be determined in another 50 cc. by reduction with zinc and titration with potassium permanganate, and the alumina corresponding to it calculated and deducted from the result of the uranium titration, giving the real percentage of alumina present.

The proportion of ferrous iron may be determined by direct titration with permanganate.

In the case of aluminium sulphate it is oxidised to sulphate by means of bromine and dealt with in the same way.—B. B.

#### *Estimation of Available Phosphoric Acid in Fertilisers containing Cotton-Seed Meal.* F. B. Daney. Pamphlet, 1890.

By dissolving fertilisers containing cotton-seed meal in concentrated nitric acid with a little hydrochloric acid, as recommended by the Association of Official Agricultural Chemists (United States) in one of their alternative methods for analysing phosphates, or in hydrochloric acid and potassium chlorate, a solution is obtained from which the phosphoric acid is not wholly precipitated by molybdic solution, therefore methods entailing these modes of treatment yield low results, which are more marked in new than in old samples of cotton-seed meal. The author has investigated this subject and finds that fusion with a mixture of equal parts of sodium carbonate and potassium nitrate, and probably also incineration and solution in hydrochloric acid are reliable modes of dealing with the fertilisers in question. In course of this investigation it was noticed that nitric acid is not an adequate solvent for incinerated phosphate.—D. A. L.

#### *Bénger and Stingl's Method of Softening Water.* W. Kalmann. Mitt. des k.k. tech. Gew.-Museums, 1890, 10—15.

To explain Bénger and Stingl's method, the author finds it convenient to divide the hardening substances into three classes, of which the first class comprises all lime salts except the bicarbonate, the second the bicarbonates of lime and magnesia, and the third all magnesium salts other than the bicarbonate. The members of the first class are

precipitated with sodium carbonate, 1 mol. of calcium oxide requiring 1 mol. of sodium carbonate, those of the second class by calcium or sodium hydrate, separately or together, 1 mol. of calcium carbonate requiring 1 mol. of calcium hydrate or 2 mols. of sodium hydrate, whilst 1 mol. of magnesium carbonate requires 2 mols. of calcium hydrate or 4 mols. of sodium hydrate since magnesium carbonate is soluble in saline water, and it is therefore necessary to precipitate the magnesium in the form of hydrate, which is much less soluble. The members of the third class are removed with sodium hydrate.

When a water contains compounds of both the first and second classes and sodium hydrate is used as the precipitant, an equivalent amount of sodium carbonate is produced, which in turn reacts with the salts of the first group, so that in this case a correspondingly less amount of sodium carbonate requires to be added. In fact, the relative amounts of sodium hydrate and carbonate required depend on the relative amounts of the compounds of these two classes which are present, and the precise mode of treatment will vary according as—

(Case 1.) The quantity of sodium carbonate required for precipitation is less than that formed in the decomposition of the salts of the second class. In this case the excess of sodium hydrate may with advantage be replaced by lime, a mixture of sodium and calcium hydrates being used.

(Case 2.) The quantity of sodium carbonate formed in the decomposition of the salts of the second class exactly suffices to precipitate the salts of the first class. In this case sodium hydrate alone is employed.

(Case 3.) More sodium carbonate is required than is formed from the sodium hydrate in the course of the precipitation; a mixture of sodium hydrate and carbonate must therefore be used.

In order to ascertain the quantities of softening reagents which are to be added to the water, the following points must be ascertained: 1. The quantity of combined carbon dioxide contained in the water, which may be readily estimated with standard acid and methyl-orange. 2. The quantity of calcium oxide contained in the water. 3. The total hardness.

Then, suppose  $a$  represents the amount of sodium carbonate equivalent to the combined carbon dioxide present, and that  $x$  represents the amount of sodium carbonate equivalent to the calcium carbonate, and  $y$  that equivalent to the magnesium carbonate, we have—

$$x + y = a \dots \dots \dots (1).$$

And if  $b$  represents the amount of sodium carbonate equivalent to the hardness due to lime salts,  $x$  parts of  $b$ , being equivalent to the calcium carbonate, and  $y$  parts of the same to other calcium salts, we have—

$$x + z = b \dots \dots \dots (2).$$

Taking  $c$  to denote the total hardness of the water, we have  $x$ ,  $y$ , and  $z$  equivalents of sodium carbonate required for the removal of the lime salts and magnesium carbonate and representing by  $r$  the soda equivalent to the magnesium salts other than the carbonate, we have—

$$x + y + z + r = c \dots \dots \dots (3).$$

The soda represented by  $z$  and  $r$  must be causticised, completely or partially, according to circumstances.

From equations (1) and (3) it follows that—

$$z + r = c - a \dots \dots \dots (4).$$

In precipitating the carbonates with sodium hydrate  $x + 2y$  parts by weight of sodium carbonate are formed, and of these,  $z$  parts are required for the precipitation of the lime salts of the above-mentioned first class. The difference  $x + 2y - z$  represents the amount or equivalent of sodium carbonate required in any of the above-cited three cases. In the first case  $x + 2y$  is less than, in the second equal to, and in the third greater than  $z$ . Now, from equations (1) and (2)—

$$x + 2y - z = 2a - b \dots \dots (5).$$

With  $2a - b = +m$  (first case),  $c - a$  parts of soda (equation 4) must be causticised for use and  $m$  parts of soda may be replaced by their equivalent of calcium hydrate.

With  $2a - b = 0$  (second case),  $c - a$  parts by weight of soda must be used in the form of hydrate, and with  $2a - b = -n$  (third case),  $c - a - n$  parts by weight of soda must be causticised and  $n$  parts used uncausticised.

The author, further, gives a volumetric method of estimating the quantity of lime contained in water. The principle of the method consists in precipitating the lime with an excess of standard solution of sodium oxalate, filtering, and determining the excess with standard potassium permanganate. 100 cc. of the water to be tested are placed in a 250 cc. flask, a few cc. of ammonium chloride solution added, then a slight excess of standard solution of sodium oxalate (0.3 gm. of crystallised salt per litre) and the flask filled to the mark. After allowing the contents to stand 2–3 hours, 100 cc. are withdrawn, filtered, and titrated with potassium permanganate, the amount of lime being estimated by the difference between the oxalate added and that found. Allowance must be made for the permanganate decolourised by the organic matters originally present in the water. Should other oxides precipitable by oxalic acid be present the ultimate result will not be affected, as such substances will require removal in the process of softening the water. The author adds that there are some waters which must be completely analysed before any method of purification can be adopted for them, but that chemists will quickly discover when they have such exceptional cases to deal with.—E. B.

#### *Determination of Lithium in Mineral Waters.* E. Waller. J. Amer. Chem. Soc. **12**, 214–223.

THERE are three methods in general use for the determination of lithium, viz., (a) Mayer's modification of the phosphate method (Ann. **98**, 193); (b) the amyl alcohol method (Gooch, Amer. Chem. Jour. **9**, 33); (c) the fluoride method (Carnot, Bull. Soc. Chim. [3], **1**, 280).

For all these processes it is necessary to obtain from a known quantity of the water the alkalis as chlorides free from admixture with other bases, and in most cases a large proportion of the sodium and potassium salts, which usually predominate largely over those of lithium, must be removed. The usual method is to acidify with hydrochloric acid, to evaporate, treat with barium hydrate, remove excess of baryta by ammonium carbonate, drive off the ammonium salts, and then to extract with alcohol to remove lithium chloride, which is inevitably accompanied by some sodium and potassium chlorides.

The spectroscope is used to determine when the washing is complete. Barium precipitates are very apt to mechanically take down lithium compounds with them, and it seems better to work with rather dilute solutions.

Then, in carrying out the phosphate method, an excess of hydrogen disodium phosphate and a moderate excess of sodium hydrate are added, the whole is evaporated to dryness and the residue is taken up with warm water; strong ammonia is next added and the mixture is warmed and allowed to stand for 12 hours. The precipitate is ignited and weighed as  $\text{Li}_3\text{PO}_4$ . Further quantities may be obtained from the filtrate. The whole of the lithium can scarcely be obtained by this method.

Gooch takes the concentrated solution of the alkaline chlorides (which should contain only about 0.2 gm. of salts in all), and adds 30–50 cc. of pure anhydrous amyl alcohol. The whole is then heated for some time carefully on a sand-bath, a few drops of hydrochloric acid are added, the heating repeated, and the alcohol then filtered into a measuring cylinder and its volume noted (usually 10–15 cc.). The undissolved salts are washed with cold amyl alcohol until no trace of lithium is perceptible in them by the spectroscope; the filtrate and washings are evaporated in a weighed platinum dish, and the chlorides converted into sulphates, ignited and weighed. From this weight, for every 10 cc. of

amyl alcohol which remained in contact with the chlorides after heating, the following deduction is made:—

	Gm.
If only sodium and lithium chlorides present .....	0.0005
" potassium " " " .....	0.00059
If sodium, potassium, and lithium chlorides present .....	0.00109

In Carnot's method the mixed alkaline chlorides after being taken nearly to dryness are extracted with a mixture of about equal volumes of 90 per cent. alcohol and ether so as to obtain the lithium chloride comparatively free from the others. After evaporating off the alcohol and ether, the salts are dissolved in the least possible quantity of water and filtered into a weighed platinum dish. Pure ammonium fluoride and ammonia are added to the concentrated filtrate, and the whole is allowed to stand 12 hours. The fluoride is collected and converted into the sulphate and weighed as such. 0.004 gm. is added for every 7 cc. of filtrate and washings (ammonium fluoride and ammonia must be used for washing the fluoride). The process is good, but tends to yield results slightly high.

An examination of various American natural lithia waters was made by the fluoride method with the result that some waters were found to contain mere traces of lithium and others only very small quantities.—T. L. B.

#### *A New Method for Determining the Value of Bleaching Powder.* L. Vanins. Zeits. f. angew. Chem. 1890, 509–510.

A WEIGHED quantity of bleaching powder is triturated with water and placed in a flask; sufficient of a solution of hydrogen dioxide is added to decompose the bleaching powder, and the oxygen which is evolved collected in a large glass jar. The volume of the water displaced is measured, and this gives the volume of the oxygen liberated, the weight of which may be found in the usual way. The results are accurate to 0.5 per cent.—A. L. S.

#### *Electrolytic Determination of Nitric Acid.* G. Vortmann. Ber. **23**, 2798–2801.

THE author has ascertained the conditions under which the nitric acid of nitrates may conveniently be reduced electrolytically to ammonia.

On passing a galvanic current through dilute nitric acid, or through a solution of the nitrate of an alkali, acidified with sulphuric acid, no ammonia is formed; but, if there be present a metallic salt whose acidified solution is decomposed by the current with deposition of the metal, then reduction of the nitric acid to ammonia takes place. A copper salt is found to work best, but complete reduction takes place also in presence of platinum or mercury salts. When zinc salts are used, complete reduction is not certain. The determination of the nitric acid is carried out as follows:—To the solution of the nitrate in a platinum dish is added a sufficiency of pure copper sulphate; the whole is acidified with sulphuric acid and electrolysed. After all the copper has been deposited, the solution is evaporated to small bulk and the ammonia is distilled as usual. It is convenient to use a current liberating 1–2 cc. of electrolytic gas per minute. The amount of copper salt to be used depends on the quantity of nitric acid present; in determining the nitric acid in potassium nitrate it is necessary to take half as much crystallised copper sulphate as potassium nitrate. A smaller amount may be used, but in such a case the copper must be more slowly deposited.

The following experiment illustrates a modification of the method which may be used in cases where a neutral nitrate is under consideration, or where other salts are present, which undergo no permanent decomposition: potassium nitrate is dissolved in water and to the solution is added a measured quantity of sulphuric acid of known strength. The positive electrode is coppered, and the current is now passed until all the copper has been deposited on the negative electrode. The excess of sulphuric acid is then

determined by titration. It is to be noted in this particular instance that part of the titrated acid is taken up by the potassium, thus—

—T. L. B.

*Volumetric Determination of Manganese.* G. Vortmann.  
Ber. 23, 2801—2803.

It is found that in presence of a salt of a sesquioxide (of aluminium or iron) manganous salts may be completely oxidised by iodine in presence of an alkali. Hence the following method serves for estimation of manganese:—The weighed salt of manganese is dissolved in water together with two to three times its weight of potash alum; a measured quantity of decinormal iodine solution is added, and some pure caustic soda solution. The whole is warmed for 5–10 minutes on a water-bath, allowed to cool, and then made up to known volume. An aliquot part is filtered through a dry fluted filter and acidified, and the excess of iodine is determined with sodium thiosulphate solution. Two atomic weights of iodine correspond to one atomic weight of manganese.—T. L. B.

*Electrolytic Separations.* E. F. Smith and L. K. Frankel.  
Amer. Chem. J. 12, 428—435.

It has already been stated by the authors (Amer. Chem. J. 12, 212) that the deposition of palladium from the solution of its double cyanide was not possible so long as any undecomposed potassium cyanide remained in the solution, and acting upon this they have now attempted the separation of palladium from the metals which are deposited from their double cyanide solutions. (See also this Journal, 1889, 639; and 1890, 108, 656, and 808—809.)

*Mercury from Palladium.*—Solutions of mercuric chloride and of palladium chloride were used in these experiments, potassium cyanide being added so that the precipitate first formed completely dissolved. The potassium cyanide was as a rule in large excess to prevent any danger of precipitating the cyanides from the solution. The current used varied from 0.08 to 0.22 cc. of OH gas per minute, and the results from -0.66 to +0.85 per cent. of the mercury actually present in the original solution.

*Silver and Cadmium* being metals like mercury and separating quite readily from cyanide solutions when acted upon by a feeble current, it was expected that they could be separated from palladium without any particular difficulty, but out of a series of 10 experiments made with varying quantities of alkaline cyanide and with currents varying from 0.5 cc. to 0.1 cc. of oxyhydrogen gas per minute, neither silver nor cadmium could be obtained free from palladium. In fact, the presence of these two metals appeared to favour the deposition of the palladium from the solution.

*Mercury from Arsenic.*—It was found that arsenic could not be deposited from solution of alkaline arsenites or arsenates, or from solutions containing alkaline cyanides. In the separation of mercury from arsenic, the precipitate formed on adding a solution of mercuric chloride to a solution either of potassium arsenite or arsenate was dissolved in potassium cyanide and subjected to the action of the current.

The separation proceeded without any difficulty, the amount of mercury found varied from -0.66 to +0.48 per cent. from the theoretical.

*Cadmium from Arsenic.*—The separation was not complete unless the arsenic existed in the solution as the higher oxide. In experiments with arsenious compounds, deposits of cadmium were obtained, which were invariably dotted over its surface with black spots of metallic arsenic. With the arsenic present as arsenate, the cadmium obtained varied from -0.93 to +0.19.

*Silver from Arsenic.*—The conditions essential for complete deposition are similar to the preceding. Attempts to separate the two metals from solutions in which the arsenic

existed as lower oxide resulted in the deposition of the arsenic with the silver. Using arseniate solutions, the results obtained varied from -0.31 to +0.63 per cent. of silver.

*Copper from Arsenic.*—The conditions are the same as in the preceding case, except that increased strength of current is necessary for the deposition of the copper. The amount of copper varied from -0.56 to +0.33 per cent. The potassium cyanide should be carefully added until the precipitate formed dissolves and the solution assumes a pink tinge. An excess of potassium cyanide is not harmful, but the greater the excess the longer will be the time required for the deposition, since the current will not deposit the copper till the excess is decomposed. Copper may be separated from arsenic in a solution containing an excess of ammonia, but the method requires skill and close attention to details for its successful performance, the copper from such a solution being deposited in a spongy coating, having a tendency to carry down and retain the salts of the alkalis which may be in the solution. In three experiments in which 0.1772 grm. of copper was present, the amount of deposit obtained varied from 0.1754 to 0.1797.

The authors having found that the oxides of tungsten and molybdenum dissolve readily in potassium cyanide, and that such solutions or solutions of ammonium tungstate or molybdate in the presence of potassium cyanide give no deposit of metal, even when electrolysed by strong currents, have based the following separations upon them.

*Mercury from Tungsten.*—For this separation, weighed quantities of mercuric chloride and ammonium tungstate were dissolved in water, the precipitate of mercury tungstate dissolved in potassium cyanide, and the resulting solution electrolysed. The amount of mercury varied from +0.09 to +0.70 per cent. The current should not exceed 0.8 cc. of OH gas.

*Silver from Tungsten.*—The conditions are the same as in the preceding case. The results varied from -0.38 to +0.95 per cent. of silver.

*Cadmium from Tungsten.*—In this separation the strength of the current is extremely important. If the current exceed 0.6 cc. of gas per minute, the deposits are apt to become spongy, and the results correspondingly high. The results usually vary from -0.38 to +0.95 per cent. of cadmium.

*Mercury from Molybdenum.*—The method was carried out as in the separation of mercury from tungsten. The results varied from +0.22 to +0.79 per cent.

*Silver from Molybdenum.*—The silver was added as nitrate, the conditions being otherwise similar to those in the preceding separation. The results varied from +0.06 to +0.70 per cent. of silver.

*Cadmium from Molybdenum.*—In these experiments the tendency of the cadmium to form spongy deposits was not so noticeable. In most cases the coating was dense and compact, and hence permitted thorough washing. The results varied from -0.66 to +0.91 per cent. of cadmium.

*Copper from Bismuth.*—Up to the present no successful method has been proposed for the electrolytic separation of these two metals. The authors have found that by adding a solution of copper sulphate to a solution of bismuth citrate containing an excess of alkali, afterwards adding a slight excess of potassium cyanide, bismuth can be deposited without carrying down any of the copper. It is necessary for complete deposition that sufficient citrate and alkali be present to keep the solution clear on the addition of the potassium cyanide. The results vary from -0.63 to +0.63. The above conditions must be carefully complied with.

In all the above separations, the deposited metal was washed with boiling water, except in the case of bismuth, where washing with cold water and absolute alcohol proved decidedly advantageous. The drying was done upon a moderately warm iron plate. The current in all cases was derived from Daniell cells of the crowfoot pattern, and the current was passed for 16 hours.—O. H.

## ORGANIC CHEMISTRY.—QUALITATIVE.

*Examination of Acetanilide.* E. Ritsert. Pharm. Zeit. 1890, **35**, 306.

MANY statements have been made on this subject, but the author is of opinion that all these are insufficient to decide whether the sample of acetanilide tested is pure or not. He has ascertained that absolutely pure acetanilide shows the following properties and reactions:—(1.) The melting point of pure acetanilide, dried at 105° C., is exactly 114° C., not 112° or 113° C., as hitherto assumed. (2.) 0.1 gm. shaken with 1 cc. of concentrated hydrochloric acid dissolves to a clear solution, which after a few moments precipitates acetanilide hydrochloride (exalgin, if present, is not precipitated). No colouration appears when a drop of nitric acid is added, whilst the presence of oxyethyl- and oxymethylacetanilide would after some time produce a yellow or brown colouration. (3.) 0.1 gm. boiled several times with 2 cc. of concentrated hydrochloric acid, and mixed, when cold, with a little chlorine water, gives a beautifully blue colouration, which, however, soon disappears. (4.) An aqueous solution of pure acetanilide shows no acid reaction (no acetic acid present), and if boiled and some drops of ferric chloride are added, a dark red-brown colouration appears. The addition of a mineral acid, however, causes this colouration to disappear. (5.) If 1 gm. of pure acetanilide be boiled with 30 grms. of water, and a drop of an aqueous solution of potassium permanganate (0.1 per cent.) be added, a pink colouration appears, which lasts for about five minutes, and does not change to yellow or yield precipitates, if the solution be boiled again (the latter takes place, if acetoluidines, free aniline, resinous products, or other impurities are present). (6.) No residue is left when heated on platinum foil (compare this Journal, 1890, 329 and 555).—H. S.

*On the Qualitative Determination of Mechanical Wood Pulp in Paper.* W. Herzberg. Mitt. König. tech. Versuchs. 1890, 132—140.

THE author shows that chemical tests are not in all cases sufficient to distinguish mechanical wood pulp from other substances which may be used in the manufacture of paper, and recommends a microscopical examination in addition to the chemical one. For this purpose portions of the paper are boiled in a dilute solution of caustic soda, then washed with water in a fine sieve, and then disintegrated by shaking with garnets; the liquid for the microscopical objects is an aqueous solution of iodine which is well known to give a yellow colour to all cells containing lignified substances. (Compare this Journal, 1890, 112.) This alone is not sufficient, but the anatomical distinctions of the different fibrous substances are so characteristic that in all cases mistakes are entirely excluded. The colouration of mechanical wood pulp under the microscope is light or dark yellow, according to the thickness of the substance. Isolated cells are not found entire, the result of the grinding process being irregular bundles or particles of cells; the ends of the cells are very seldom found. Very characteristic are the pitted vessels, the concentric circles of which are generally plainly discernible. Also the cells of medullary rays are very characteristic of mechanical wood-pulp. Contrary to these properties, imperfectly boiled wood cellulose is of a lighter colour, and on account of the chemical treatment, only isolated cells or parts of them are found microscopically. Unseparated bundles or pieces of cells are never found, whilst these, as we have seen, are the characteristic features of mechanical wood-pulp. The ends of the cells are always found in great numbers. On account of the chemical treatment, the structure of the cells is much less discernible, especially the concentric circles of pitted vessels which appear only as light spots of circular or elliptic shape. The cells of medullary rays which are, as we have seen, highly characteristic of mechanical wood pulp, are entirely absent in imperfectly boiled wood cellulose. From all these statements it is evident that the differences between these two materials are so great and characteristic that errors in testing are entirely out of the question.—H. S.

## ORGANIC CHEMISTRY.—QUANTITATIVE.

*Lubricating Oils.* A. C. J. Charlier. The Engineer, 1890, 305—306.

See under XII., page 1043.

*Determination of Morphine in Opium.* G. Looff. Apoth. Zeit. 1890, **5**, 271.

1. *Opium Powder.*—5 grms. of fine opium powder were well mixed with water, diluted to 75 grms., and after having been shaken several times, allowed to stand for about two hours and then filtered. To 60.8 grms. of the filtrate (containing 4 grms. of opium) 0.2 gm. of oxalic acid were added, this mixture was well shaken and allowed to stand for half an hour. Then 5.2 grms. of potassium carbonate solution (1:2) were mixed with it without shaking, and the solution quickly filtered through a dry folded filter before any morphine was precipitated. 16.5 grms. of the filtrate (containing 1 gm. of opium) were mixed in a small Erlenmeyer flask with 5 grms. of pure ether, the flask stoppered and vigorously shaken for 10 minutes. Then the ether was evaporated at ordinary temperature, the residue filtered, the precipitate thoroughly washed with water, saturated with ether, and dried at 40—50° C. The morphine thus obtained was removed from the filter by means of a small brush, and dried until the weight remained constant.

2. *Opium Solution.*—To 50 grms. 0.2 gm. of oxalic acid were added, and the solution evaporated to the consistency of treacle, diluted by slowly adding water to 70 grms., 5 grms. of potassium carbonate solution (1:2) added, filtered and 15 grms. of the filtrate further treated as above.

3. *Opium Extract.*—2.5 grms. were dissolved, 0.2 gm. of oxalic acid added, diluted to 70 grms., and further treated as No. 2.

E. Schmidt states that this method gives very exact results, the maximum differences of various tests having been not more than 0.3 per cent. It gives about 1 per cent. of morphine less than Dieterich's method, as more liquid is used in the described test, and as the morphine obtained is purer.—H. S.

*Determination of Tartar, Tartaric Acid, and Malic Acid in Wines, and some Remarks on the Inorganic Salts contained in Wines.* M. Schneider. Mitt. a. d. Pharm. Inst. d. Univers. Erlangen, 1890, **3**, 57; Chem. Zeit. Rep. **14**, 174.

THE method proposed by the "Reichsgesundheitsamt" (Chem. Zeit. **8**, 965) for the determination of tartar and tartaric acid is a good one, but it gives somewhat too high results, as the greater part of the acid salts contained in wines is by this method precipitated and titrated together with the tartar. It is therefore necessary for the exact determination of tartar and tartaric acid, to dissolve the precipitated tartar in boiling water, to neutralise with decinormal alkali, evaporate, incinerate, and to determine tartar and tartaric acid from the ash (carbon dioxide determination). It has not been possible to determine malic acid in wines by the methods employed hitherto, as part of this acid was always decomposed. The author recommends that the wine be neutralised by decinormal alkali, evaporated, incinerated, and the tarter determined as above. From this calculation, which is of course too high, the actual amount of tartar and tartaric acid (calculated as tartar) is subtracted, and the difference corresponds to the quantity of malic acid, and is calculated accordingly.

The following substances have been found in wines by the author:—Free tartaric and malic acids, tartar, acid potassium phosphate, sodium chloride, calcium sulphate and acid calcium phosphate, magnesium phosphate and ferric phosphate.

For making the above tests the author recommends the following process:—100 cc. of wine are evaporated to a syrup, treated with alcohol and the mixture allowed to stand

in a cool place for about 12 hours, before dissolving the tartar in boiling water. The incineration has to be effected very carefully.—H. S.

*Determination of Caffeine in Tea.* F. Vité. Mitt. a. d. Pharm. Inst. d. Univers. Erlangen, 1890, **3**, 113; Chem. Zeit. Rep. **14**, 174—175.

THE author considers Hilger's method to be the best, and applies it as follows:—5 grms. of tea are boiled for three consecutive times for one hour, each time in 300 cc. of water. The extract obtained is evaporated to one-fourth of its volume, and, while hot, mixed with freshly precipitated lead hydroxide and quartz sand; then evaporated on the water-bath, and extracted with chloroform for three hours in Soxhlet's or Flückiger's apparatus. Then the chloroform is removed by distillation, the residue dissolved in hot water, filtered, the filtrate evaporated on the water-bath, and the dry residue weighed.—H. S.

*A New Method for the Determination of Theine in Tea.* G. L. Spencer. Jour. Anal. Chem. 1890, **4**, 158.

To two or three grms. of finely powdered tea, 3 or 4 cc. water are added, the mixture boiled, allowed to stand, and then decanted. This operation is repeated seven times, the residue washed, and about 8 cc. of basic lead acetate added to the solution, which is then filtered, washed with hot water, and freed from lead with sulphuretted hydrogen; 5 grms. of hydrate of magnesia or of lime are added, the filtrate concentrated to about 50 cc., filtered, the residue washed with hot water, and the filtrate, when cold, seven times extracted with chloroform. Then the chloroform is removed

by distillation, the theine thus obtained dried at 75 °C., and weighed. The theine prepared in this way is very pure. (Compare this Journal, 1886, 178.)—H. S.

*The Oxidation of the Sulphur contained in Organic Bodies.* Berthelot, André, and Matignon. Compt. Rend. **111**, 6—9.

THE various methods in use for the oxidation of organic sulphur into sulphuric acid are tedious and difficult. The process described by the authors is not only a very accurate, but also a very rapid one, and is applicable to all organic sulphur compounds. It consists in burning the substance with oxygen under a pressure of 25 atmospheres in a calorimetric bomb, in presence of 10 cc. of water. The combustion takes place instantaneously, dilute sulphuric acid only being produced, provided the substance taken contained sufficient hydrogen. Bodies poor in hydrogen lead to the production of a little sulphurous acid. In such cases the substance must be mixed with from one-half to its own weight of camphor prior to combustion. Finally, the contents of the bomb are washed into a beaker, and the sulphuric acid is precipitated by barium chloride in the usual way. The test analyses, which include the estimation of sulphur in such bodies as albumin, taurine, carbon disulphide, &c., are exceedingly satisfactory.—H. T. P.

*Wet Method of Estimating Carbon in Organic Substances.* J. Messinger. Ber. **23**, 2756—2760.

THIS is an improvement on the author's method of two years ago (Ber. **21**, 2910). The method is now applicable to compounds with which previously low results were obtained.

THE ESTIMATION OF CARBON IN ORGANIC SUBSTANCES.

The substance is weighed into a small tube 24 mm. long and 11 mm. wide, and is then introduced into the decomposition flask, which contains 6—8 grms. of chromic acid, care being taken that the chromic acid does not come into contact with the substance under analysis. The decomposition flask is fitted with a thistle funnel, and is connected to the reversed condenser and apparatus shown in the figure. 50 cc. of concentrated sulphuric acid are run into the flask. During the whole of the operation a gentle current of air (free from carbon dioxide) is passed through the apparatus. The asbestos plate underneath the flask is then warmed and thus the flask and contents are warmed by radiant heat from the plate alone until the sulphuric acid darkens. At this point, where decomposition of

the organic substance begins, the flame is entirely removed. The carbon dioxide (with some carbon monoxide) passes through the condenser and then over a heated mixture of copper oxide and lead chromate contained in a tube 15 cm. long. The gas ( $\text{CO}_2$ ) then passes through a U-tube, in one limb of which is sulphuric acid, in the other glacial phosphoric acid.

Thus dried it passes through weighed potash bulbs, after which is placed for safety a small tube containing soda lime and phosphoric acid. After the lapse of about 20 minutes warming may be once more proceeded with in the same manner as before, and after about 2½ hours the asbestos plate may be placed directly below the flask, and more strongly heated.

The whole operation is very easily carried out, and needs no watching.

With substances containing halogens, it is advisable to place, after the copper oxide tube, a small washing flask containing potassium iodide solution.—T. L. B.

*Apparatus for the Determination of Ammonias in Filter Sand and Sewage.* A. Hazen. Amer. Chem. J. **12**, 427—428.

In examining sand from filters it has been thought desirable to determine free and albuminoid ammonia, as this indicates the amount of organic matter stored, in the same terms as given for the filtered water or the sewage. The author carries out the determination by blowing steam, generated in a flask containing ammonia-free water, through another flask containing a quantity of the sand to be tested, and connected with a condenser. The steam very rapidly carries off the free ammonia which is invariably contained in the first 50 cc. of the distillate. Alkaline permanganate is then added to the sand, and the steaming continued. The first portion which distils over usually contains at least eight- or nine-tenths of the whole and the second portion almost all the rest.

The amount of free ammonia obtained in the case of sewage is the same as that found by the usual process of dilution with pure water and direct distillation. The albuminoid ammonia is commonly a little greater, owing to the concentration of the permanganate, but the results are sharper, and different determinations agree with each other more closely.—O. H.

*Volumetric Determination of Phenols.* J. Messinger and G. Vortmann. Ber. **23**, 2753—2756.

THE authors have described (Ber. **22**, 2312) a class of iodised phenols obtained by the action of iodine on alkaline solutions of the phenols. The formation of these compounds is made use of for the estimation of phenols, and a quantitative method has been worked out in the case of phenol, of thymol, of naphthol, and of salicylic acid.

**Phenol.**—In the reaction between iodine and an alkaline solution of phenol, 6 atoms of iodine are required for each molecule of phenol. The quantitative determination of phenol is carried out in the following manner:—2—3 grms. of the phenol are dissolved in caustic soda (at least 3 mols. of caustic soda to one of phenol). The solution is diluted to 250 or 500 cc., and of this, 5 or 10 cc., accurately measured, are warmed to about 60° in a small flask; decinormal iodine solution is now run in until the liquid has attained a deep yellow colour, due to excess of iodine. The whole is cooled, acidified with dilute sulphuric acid, and made up to 250 or 500 cc., and an aliquot part (about 100 cc.) is filtered and titrated with decinormal sodium thiosulphate solution. The amount of iodine used, multiplied by the factor 0.123518, gives the quantity of pure phenol. Thus:—

$$\begin{array}{rcl} 1 \text{ mol. phenol} & = & 93.78 \\ 6 \text{ atoms iodine} & = & 759.24 \\ & = & 0.123518. \end{array}$$

**Thymol.**—From an alkaline thymol solution the whole of the thymol is precipitated in the cold by iodine. For each molecule of thymol 4 atoms of iodine are necessary. The factor here is therefore—

$$\begin{array}{rcl} 1 \text{ mol. thymol} & = & 149.66 \\ 4 \text{ atoms iodine} & = & 598.64 \\ & = & 0.2956772. \end{array}$$

For the determination 0.1—0.3 grm. of thymol is dissolved in caustic soda (4 mols. of caustic soda to 1 of thymol), the solution has excess of decinormal iodine solution added to it, and is then acidified and further treated as in the case of phenol.

**$\beta$ -Naphthol.**—The alkaline solution (4 mols. of caustic soda to 1 of naphthol) must be heated to 50—60° before the addition of the iodine. The determination is carried out exactly as in the case of phenol. The factor is—

$$\begin{array}{rcl} 1 \text{ mol. naphthol} & = & 143.66 \\ 3 \text{ atoms iodine} & = & 379.62 \\ & = & 0.37843106. \end{array}$$

**Salicylic Acid.**—For solution of the salicylic acid it seems best to take 4 mols. of caustic soda to 1 of salicylic acid.

If too little alkali has been used a yellowish precipitate forms before an excess of iodine has been added; in such a case it is necessary to dissolve this precipitate by further addition of caustic soda. Precipitation should first occur when excess of iodine has been added. The alkaline solution requires warming to 50—60° before addition of the iodine. The factor here is—

$$\begin{array}{rcl} 1 \text{ mol. salicylic acid} & = & 137.67 \\ 6 \text{ atoms iodine} & = & 759.24 \\ & = & 0.18132606. \end{array}$$

Of course alkali free from nitrite must be used, or else the amount of iodine set free by a certain number of cc. of alkali on acidifying must be ascertained, and then the alkali used must always be accurately measured.—T. L. B.

*A Simplification of the Volumetric Determination of Free Acid in Oils.* Holde. Mitt. Königl. tech. Versuchs. 1890 151—153.

The method described in Mitt. Königl. tech. Versuchs. 1889, 116—119 (this Journal, 1890, 112), may be conveniently arranged for practical purposes as follows:—

1. **Light-coloured Oils.**—Ethereal solutions of which show the colour reactions of phenolphthalein.

The funnel B (see Fig. 1) is fitted into the cork A, which has two holes; and the cork then inserted into the mouth of the Erlenmeyer flask C, whose capacity is about 300 cc.; B is marked at *a* for 10 cc. and this quantity of the oil to

Fig. 1.

Fig. 2.

Fig. 3.

be tested, is poured into it, then the stop-cock S is opened and after the oil has flowed into C, B is washed with a neutralised mixture of ether (8 parts) and alcohol (2 parts) containing phenolphthalein, until the flask is filled to about c. Then A and B are removed and the liquid titrated. The burette D (see Fig. 2) contains an alcoholic solution of caustic soda 1 cc. of which corresponds to 0.005 gm. of sulphuric anhydride ( $\text{SO}_3$ ). The titration is continued until the red colouration becomes permanent. The graduation of D is such as to indicate directly the percentage of free acid contained in the oil, calculated as sulphuric anhydride, the latter being calculated as follows:—

If  $x$  cc. caustic soda be necessary to neutralise 10 cc. of oil, containing 1 per cent. free acid, then we have the equations—

$$\frac{10 \cdot x \times 0.005}{0.914} = 1, \text{ and } x = 18.3 \text{ cc.}$$

Where 0.914 is taken as an average specific gravity of the oils which are usually used for lubricating purposes, and 0.005 gm. as the quantity of sulphuric anhydride corresponding to 1 cc. of caustic soda, hence 18.3 cc. of the burette correspond with 1 per cent. of free acid in the oils, and this space is divided again so as to enable the operator to read  $\frac{1}{10}$ ,  $\frac{1}{100}$ ,  $\frac{1}{1000}$ , &c. per cents. Two per cent. is the maximum which the burette indicates.

2. *Dark-coloured Oils.*—The solutions of which in ether and alcohol do not show the reactions of phenolphthalein.

20 cc. of the oil to be tested are poured into the graduated and stoppered measure E (see Fig. 3), and 50 cc. of absolute alcohol added. Then both liquids are well shaken and allowed to stand. After the separation of the liquids 25 cc. of the alcoholic portion are poured into the Erlenmeyer flask, 20 cc. of the above described mixture of ether, alcohol, and phenolphthalein added, and then the liquid titrated as above. When the acid found is more than 0.03 per cent. then the remaining 25 cc. alcohol in the graduated measure has to be poured off and again shaken with 50 cc. of absolute alcohol. A second titration is then made, and the amount of acid found this time is the correct one. The calculation is the same as above, as for each titration 10 cc. oil (of the 20 cc. taken) were used.

The advantage of working according to this method lies in the convenience with which the necessary quantities of the substances are easily and exactly obtained, and in entirely excluding all possible losses of substance, as well as all tedious calculations.

The following table gives proofs of the correctness of this method, by comparing it with the method of Geissler (see this Journal, 1890, 112):—

No.	Kind of Oil.	Percentage of Acid calculated as $\text{SO}_3$ .	
		Geissler.	Holde.
1	Refined rape oil.....	0.64	0.64
2	" " .....	0.60	0.59
3	" " .....	0.95	0.95
4	Olive oil .....	0.44	0.44
5	" .....	2.82	2.82
6	Refined rape oil.....	1.00	1.01
7	" " .....	0.63	0.61
8	" " .....	0.28	0.28

—H. S.

#### *A Method for Comparing the Solidifying Points of different Sorts of Tallow.* Finkener. Mitt. König. tech. Versuchs. 1890, 153—158.

In an article upon the determination of the fatty acids of tallow, &c. (see Mitt. König. tech. Versuchs. 1889, 27—41; this Journal, 1889, 423—424), it is explained that different

quantities of tallow used in the tests, and different ways of cooling the melted tallow, change the solidifying points considerably. For comparisons it is therefore essential that the working of the methods should always be the same.

The author used for the following experiments small globular flasks (see figure) of about 50 mm. diameter, and instead of covering them with wadding (compare this

THE SOLIDIFYING POINTS OF TALLOW.

Journal, 1889, 423), to effect a slow cooling of the tallow, he found it a more practical arrangement to place the flasks containing the tallow in a wooden box of 144 mm. in height and 70 mm. in length and width (see figure). In the middle of the bottom is fixed a piece of cork 22 mm. high, with a small hollow in which the flask rests. A thermometer is so arranged as to bring its bulb into the centre of the flask. The flask is marked for a determined quantity of tallow, and the thermometer has a rim, so that the tallow is always under the ordinary atmospheric pressure. The top of the box has two flaps, which can be closed as the figure shows, by which arrangement the thermometer as well as the flask are kept in the middle of the box. The middle part of the flask is 25 mm. wide, the upper 12 mm. The bulb of the thermometer has 9 mm. and its tube 5 mm. diameter.

The graduation of the thermometer which indicates  $\frac{1}{2}^{\circ}\text{C}$ . should go to about  $120^{\circ}\text{C}$ . This apparatus is used as follows:—150 grms. of tallow are melted on a water-bath (the water boiling), and left there not less than half an hour. Then the melted tallow is poured into the flask till the mark is reached, about 80 grms. of tallow being used for each test. Then the thermometer is put into the tallow and the flask placed in the box, as described above. Every two minutes the temperature is noted, the solidifying point being arrived at either when the temperature remains constant for some minutes, or when it ceases to fall and rises again a little; in the latter case the highest point of the rising is the solidifying point. The time necessary for the entire test is two hours; for the cooling alone about one hour; in working with three apparatus at the same time, three tests can conveniently be made in three hours. After the test the tallow is melted again in boiling water, the flask emptied, and cleaned with a little ether. The author has made experiments with different sorts of tallow with this apparatus, and has ascertained what effect alterations in the described details of making the experiments have upon the temperature of the solidifying points. If different maximum temperatures (from  $50^{\circ}$  to  $100^{\circ}\text{C}$ .) are applied in melting the tallow on the water-bath, the experiments show that the solidifying points become lower with the rising of the maximum temperature, but that they always become alike for the same sort of tallow after it has been heated to  $100^{\circ}\text{C}$ . for half an hour; further heating does not affect the test. At ordinary temperatures this result is not changed, but if the temperature of the testing room is

low (about 10° C.) a further reduction of 0.2° C. takes place. It is of no importance at what temperature of the tallow the flask is placed in the box, provided that such temperature is at least 10° C. above the solidifying point. (Compare also this Journal, 1890, 112, and 743—744).

—H. S.

*Determination of Fats in Soap.* M. Saupe. Pharm. C. H. N. F. 1890, 11, 314.

The author recommends shaking with ether as follows:—Two grms. of fine soap shavings taken from the interior of the sample to be tested, are dissolved in 50 cc. of water in a stoppered measure, and 5 cc. of dilute sulphuric acid (1:4) added. Then 54 cc. of dilute ether are added, the mixture shaken three or four times, and allowed to stand. 20 cc. of the clear ether solution of the fats thus obtained are withdrawn with a pipette, put into a small beaker, the ether evaporated, and the residue weighed. The percentage is obtained by multiplying by 125.—H. S.

*The Application of the Oleo-refractometer to the Detection of Adulterations.* F. Jean. Bull. Soc. Chim. [3], 4, 105—108.

The apparatus consists of a collimator, telescope, and a small metal vessel fitted with parallel plate glass sides, and into which is placed a small silver tube with plate glass ends, arranged at a definite angle. The apparatus is so arranged that the light passes through the collimator, the plate glass sides of the outer metal vessel and interior silver cylinder, and thence to the telescope. The collimator, instead of having a slit, has a semicircular stop, which leaves half the field in darkness; the telescope is furnished with a glass scale placed in the focus of the eye-piece. If both the outer metal vessel and the interior silver tube be filled with the same oil, there will be no refraction, and the field will be divided into a light half and a dark half. If the inner tube be filled with a different oil, there will be refraction, the amount depending on the nature of the oil, and being measured by the displacement of the line dividing the field into dark and light, relative to the scale of the telescope. If then one of these oils is known to be a pure sample, and the other a commercial sample, if the latter is pure there will be no refraction, and if it is not, the amount of refraction will indicate the nature of the adulteration and the amount. This method is stated to be particularly adapted to the examination of lard and butter. (See this Journal, 1890, 218.)—A. L. S.

*Japan Wax.* O. Kleinstück. Chem. Zeit. 14, 1303—1304.

In continuation of work previously done and recorded in the Arch. Pharm. 26, 166, the author obtained three samples of Japan wax from different sources for the present investigation. The closeness with which the specific gravity of Japan wax approximates to that of water, coupled with its high coefficient of expansion, gives rise to the curious phenomenon of its floating in water at temperatures above 18° C. and sinking below 15° C. This behaviour is modified by the property, which it shares with other similar substances, of being lighter after fusion and cooling than is proper to the temperature at which it is, its specific gravity becoming normal only some time after it has solidified.

The high coefficient of expansion of Japan wax allows of direct demonstration, a bar 625 mm. long expanding 4 mm. when its temperature is raised from -6° C. to 22° C. A similar experiment with a rod of beeswax gave 3 mm. as a result. The following interesting table, given in the next column, lays bare the whole reason for what is at first sight very puzzling behaviour.

The specific gravity of the Japan wax examined was so constant for fixed temperatures both in the case when it had been recently fused and in the case when it was in its normal and denser condition, that it was found possible to calculate to a nicety the temperature to which water in which it was placed had to be brought in order that the wax might be of the same specific gravity and sink or float indifferently. The change of specific gravity was sufficiently sharply defined to

Temperature °C.	Specific Gravity compared with that of Water at 4° C.		
	Japan Wax.		Water.
	In the Normal Condition.	After recent Fusion.	
6.5	..	1.00237	0.99995
7.2	1.00737	..	0.99991
17.0	..	0.99123	0.99884
17.5	0.99846	..	0.99875
23.0	..	0.98747	0.99762
26.5	0.98615	0.98683	0.99674

permit of a difference of 0.5° C. at the critical temperature determining whether it would float or sink. The mean of the temperature at which it just floated and that at which it just sank was in all cases almost absolutely identical with the calculated temperature at which the specific gravities of the water and wax should be the same. The precision of the occurrence of the phenomenon almost raises it into a means of differentiating Japan wax from similar bodies.

—B. B.

ANALYTICAL AND SCIENTIFIC NOTES.

*On the Action of Nitrous Anhydride (Nitrogen Trioxide), dissolved in Carbon Disulphide, upon different Organic Compounds.* L. H. Friedburg and J. A. Mandel. J. Amer. Chem. Soc. 12, 7—12 and 54—57.

The authors aim at modifying the intense action of free nitrous anhydride on organic bodies by the intervention of a diluent, and for this purpose they dissolve carefully-prepared nitrous anhydride in carbon disulphide. The substance to be acted upon is also dissolved preferably in the same solvent, and the heat of reaction is reduced as much as possible by keeping the solutions in a freezing mixture. By operating in this way on benzene, the products were exclusively mono-nitrobenzene and para-dinitrobenzene. Phenol yielded a mixture of ortho-nitrophenol, para-nitrophenol, and nitrosophenol. Weselsky had previously carried out this reaction in a similar manner, using ordinary ether as a diluent, but he obtained diazophenol nitrate in place of the nitrosophenol.

Diphenylamine was submitted to the reaction in three different ways: by solution in absolute alcohol, in carbon disulphide, and in carbon disulphide in presence of sulphur. By the first method para-mononitro-, para-dinitro-, and ortho-dinitro-diphenylamine were obtained, whilst the other two methods yielded principally para-mononitro-diphenylamine, the sulphur taking no part in the reaction.

The authors apply the method to diphenyl, prepared by passing the vapour of benzene in an atmosphere of carbonic acid several times through a red-hot tube, and purifying the product by distillation with steam and crystallisation from alcohol. On treatment with nitrous anhydride in the manner already described, a substance was obtained which crystallised from alcohol in long colourless brilliant needles, melting at 113° C., which proved to be para-mononitrodiphenyl. Benzoinitrile was prepared by Krüss's method by heating to 190° C. 2 mols. of benzoic acid with 1 mol. of lead sulphocyanide, but no notable reaction was obtained on treating it with nitrous anhydride. Benzaldehyde under the same treatment was simply oxidised to benzoic acid. Benzoic acid furnished a nitroso compound which, after purification, melted at 114° C., and gave numbers agreeing with the formula for nitrosobenzoic acid.—G. H. B.

*The Diffusion of Carbon Dioxide through Caoutchouc.* Kobbe. Thonind. Zeit. 1890, 14, 297.

The author has constructed an apparatus to show that carbon dioxide easily diffuses through caoutchouc. Lime water to about half an inch in depth is poured into two

Erlenmeyer flasks A and B, and A closed loosely, B airtight with corks. A and B are connected with each other by a U-tube, the ends of which reach the lime water in both flasks. The cork of B has two other holes, through which an india rubber tube of 40 cm. length is passed airtight, forming a sling or bend inside B, but not touching the lime water. One end of this tube passes into the open air, the other one is connected with a Woulfe's bottle. The lime water in B remains almost perfectly clear as long as atmospheric air goes through the india-rubber tube, but when the tube is filled with carbon dioxide and closed by screw clamps, and the apparatus allowed to stand, then the lime water in B loses its transparency, whilst that in A shows very little change. After 24 hours the precipitates of both bottles were filtered, washed, and heated to redness. It was thus found that B contained 0.0598 grm. more calcium carbonate than A. The author also ascertained that hydrogen does not show the same degree of diffusibility through caoutchouc as carbon dioxide.—H. S.

*On the Phenomenon of Coagulation.* A. Béchamp. Bull. Soc. Chim. [3], 4, 181—186.

The author points out the great confusion which exists in the use of the term "coagulation." Chemists now use the word "coagulate" as a synonym of "to become insoluble," and when albuminoids are referred to, coagulate = "to become insoluble in water." All colourless albuminoids which are precipitated from the aqueous solution on heating have been by some considered identical: casein has been identified with blood-fibrin, &c., and the precipitation of the albumen has been attributed to the presence of some acid or base as an impurity. Wurtz and the author have however both shown that some pure soluble albumens exist which are coagulable by heat, though other pure albumens are incoagulable.

The term coagulation has been applied to the spontaneous curdling of both fresh and boiled milk, to the curdling of fresh and boiled milk by addition of rennet and to their coagulation by means of a suitable acid. Yet these are essentially different phenomena, since fresh milk never curdles without previously becoming acid, whereas boiled milk may remain neutral and still curdle; rennet coagulates milk even when it is alkaline, &c. It is also evident that curdling in these cases is not again the same as that produced by the addition of an acid.

The author intends to investigate the subject completely; the present communication, however, deals experimentally only with the coagulation of milk by an addition of acid.

*Casein and the other Albuminoids of Milk.*—The author has previously shown that cow's milk does not contain casein, but alkaline caseinates, and concludes that when acetic acid precipitates casein, this is merely a phenomenon of displacement and not of "coagulation proper."

*Pure casein* is prepared as follows: Pure acetic acid is added drop by drop to cow's or goat's milk as soon as possible after it has been drawn from the udder, until the liquid turns litmus paper the colour of onion skin; at this point the diacaseinate first formed is completely decomposed. The milk must *not* be warmed previously to this operation, as the casein obtained would then contain lactalbumin. Shortly after the addition of the acid the milk curdles. It is then filtered and the whey comes through quite clear. The casein precipitated has brought down with it the milk globules and "microzymas"; it must be thoroughly washed to free it from all soluble milk constituents, drained and then treated with ether to dissolve out all the fatty matters. The mass is then again washed with water and stirred into a volume of water equal to that of the milk originally taken; and the liquid is made slightly but unmistakably alkaline with ammonium sesquicarbonate. The casein-precipitate dissolves, but the solution remains turbid owing to the presence of the debris of the globule envelopes and the microzymas. Filtration is hastened by heating up filter-paper with the solution. To the clear filtrate acetic acid is added as before, in just sufficient amount to exactly precipitate the casein.

The casein is then washed with water, and if the product is pure the wash-water will give no precipitate

either on heating or on addition of alcohol. If a precipitate be formed under these circumstances the whole mass must be redissolved and reprecipitated. Prolonged washing with water frees the casein from every trace of acetic acid.

By the above process a pure product is obtained with constant properties. The specific rotatory power in ammoniacal solution for the sensitive tint is  $[\alpha]_D = -130^\circ$ . The lower numbers obtained by previous observations are due to an admixture of lactalbumin. Casein is only slowly and slightly soluble in water at the temperature of the air; 1 litre of water left in contact with excess of the substance for 52 hours, with frequent agitation, dissolves 1.005 grms.

The specific rotatory power of the aqueous solution for sodium light is  $[\alpha]_D = -117^\circ$ . Gradually heated with water to  $100^\circ$  casein becomes softer and softer, and seems to melt. The water in contact with the soft mass contains 2.37 grms. of casein per litre. The solubility therefore increases with rise of temperature. When the quasi-fluid casein cools it becomes hard and may be powdered by grinding under water, redissolved in ammonium sesquicarbonate, and reprecipitated in its original state by the addition of acetic acid. Neither heat nor the addition of an acid coagulates casein solutions.

Casein solutions act on litmus like carbonic acid, and acid caseinate of potassium, sodium, ammonium, and calcium may be obtained which redden litmus and are not precipitated by carbonic acid.

The caseinates of these bases form solutions which are neither precipitated by alcohol nor coagulated on heating. At the boiling point, however, the solution of calcium caseinate becomes cloudy, but again becomes clear on cooling; casein is therefore a substance quite distinct from albumin.

*Whey Albuminoids.*—Whey contains other albuminoids, differing from casein. Whey is coagulable by heat, and the coagulum formed is insoluble both in water and ammonium sesquicarbonate. [It is evident, therefore, that in the preparation of pure casein, as above, the milk must not be warmed before precipitation.]

To the clear whey, "alcohol at  $95^\circ \text{C}.$ " is added until no further precipitate is formed, a volume of alcohol at least equal to twice the original volume being necessary. A voluminous precipitate is formed, which is collected on a filter and washed with "alcohol at  $80^\circ \text{C}.$ " until it is freed from lactose; it is then drained, but before it dries it is stirred into water and after some time filtered. A certain portion of the mass dissolves in water, from which it may be reprecipitated by alcohol; it is therefore washed with water till the wash water gives no precipitate with alcohol. The undissolved portion is taken up with a dilute solution of ammonium sesquicarbonate; a solution of an albuminoid and an inorganic residue are thus obtained. The albuminoid may be precipitated from its solution by means of acetic acid and this product is *lactalbumin*. The portion soluble in water is *galactozymase*; it must be freed from lactalbumin by dissolving in water and reprecipitating several times. The final product is entirely soluble in water, and it may be found impossible to reprecipitate it with alcohol except by adding a trace of sodium or ammonium acetate to the solution. The galactozymase of cow's milk renders starch paste fluid, but does not convert it into sugar.

It is evident that lactalbumin exists in the soluble state in milk, but the treatment with alcohol, which precipitates it, renders it at the same time insoluble in water, though it remains soluble in a solution of ammonium sesquicarbonate. If, however, it be stirred into water and heated to  $100^\circ$ , it contracts without softening, and then becomes insoluble not only in ammonium sesquicarbonate, but also in dilute ammonia.

Galactozymase, on the other hand, is in no wise coagulable by alcohol, but it also yields solutions which are coagulated by heat, and they thereby lose their "zymasic" function.

The study of the specific rotatory power of lactalbumin and galactozymase proves them to be definite chemical compounds.

The author intends to publish further results shortly.

—P. J. H.

## New Books.

**THE THRESHOLD OF SCIENCE.** A variety of simple and amusing experiments illustrating some of the chief Physical and Chemical Properties of Surrounding Objects and the effects upon them of Light and Heat. By C. R. ALDER WRIGHT, D.Sc., F.R.S., Lecturer on Chemistry and Physics in St. Mary's Hospital Medical School, London. London: Charles Griffin and Co., Exeter Street, Strand. 1891.

OCTAVO volume elegantly bound in cloth and gilt, price 7s. 6d., a volume more plainly bound in cloth being offered at 6s. It contains Frontispiece, Table of Contents, Introduction, and Text covering 384 pages, concluded by a copious Alphabetical Index. There are upwards of 203 well-executed wood engravings. The intent of the work may be readily gathered, especially after another glance at the title, from the following paragraph in Dr. C. R. Alder Wright's introduction:—"Whilst the juvenile philosopher finds pastime and entertainment in constructing simple apparatus and preparing elementary experiments, he may at the same time be led to observe correctly what happens, to draw inferences and make deductions therefrom, and by comparing together the results obtained in different cases may gradually acquire some degree of elementary training in the proper exercise of those mental qualities which systematic scientific education chiefly calls forth; and in addition may pick up a variety of pieces of information as to the 'why and wherefore' of things connected with the phenomena of nature generally, and more particularly with matters of every-day occurrence, especially the various arts and manufactures and the innumerable scientific applications nowadays met with on all sides of every-day life." It is claimed, as a special advantage, that the book is written not with a view to aid in preparing for examinations, but rather to foster the habit of scientific thought in an elementary way and of deliberate experimental inquiry.

The work is classified as follows:—§ 1. States of Matter. § 2. Physical Changes of State, due to Heat and Pressure and not accompanied by Chemical Action. § 3. Changes of State, due to Solution, not accompanied by Chemical Action. § 4. Solution and Separation from Solution by Actions involving Chemical Changes. § 5. Chemical Actions producing Change of State without the Employment of Solvents. § 6. Physical Adhesion and allied phenomena of Surface Action. § 7. Effects of Heat upon Bodies, other than Change of State, and Production of Chemical Action. § 8. Radiant Action; Visible Light. § 9. Radiant Action; Invisible Light.

**A TREATISE ON ELECTRO-METALLURGY.** Embracing the Application of Electrolysis to the Plating, Depositing, Smelting and Refining of various Metals, and to the Reproduction of Printing Surfaces and Art-work, &c. By WALTER G. McMILLAN, F.I.C., F.C.S., Chemist and Metallurgist to the Cossipore Foundry and Shell Factory; late Demonstrator of Metallurgy in King's College, London. London: Charles Griffin and Co., Exeter Street, Strand. 1890.

OCTAVO volume, bound in cloth, price 10s. 6d. It contains Preface, Table of Contents, List of Tables used in the treatise, 316 pages of Subject-matter, 29 pages devoted to a glossary of substances commonly employed in Electro-metallurgy, 12½ pages devoted to Addenda, chiefly composed of tables or tabulated matter, terminated by a List of Antidotes to Poisons contained amongst the substances used in Electro-metallurgy, and a copious Alphabetical Index. The text is illustrated by 101 effective and well-executed wood engravings. The matter is brought well up to date, including descriptions such, for example, as that of Elmore's recent process for the manufacture of seamless copper tubes of extraordinary strength and tenacity by electro-deposition of the pure metal, meanwhile continually burnishing it during the whole course of the depositing operation.

The work is sub-divided as follows:—CHAP. I. Introductory and Historical. II. Theoretical and General. III. Sources of Current. IV. General Conditions to be observed

in Electro-Plating. V. Plating Adjuncts and Disposition of Plant. VI. The Cleansing and Preparation of Work for the Depositing Vat, and subsequent Polishing of Plated Goods. VII. The Electro-deposition of Copper. VIII. Electrotyping. IX. The Electro-deposition of Silver. X. The Electro-deposition of Gold. XI. The Electro-deposition of Nickel and Cobalt. XII. The Electro-deposition of Iron. XIII. The Electro-deposition of Platinum, Zinc, Cadmium, Tin, Antimony, and Bismuth; Electro-chromy. XIV. The Electro-deposition of Alloys. XV. Electro-metallurgical Extraction and Refining Processes. XVI. The Recovery of certain Metals from their Solutions or Waste Substances. XVII. The Determination of the proportion of Metal in certain Depositing Solutions. XVIII. A Glossary of Substances commonly employed in Electro-metallurgy. Addenda.

**UNTERSUCHUNGEN AUS DER PRAXIS DER GÄRUNGS-INDUSTRIE.** VON DR. EMIL CHR. HANSEN. I. Heft. Zweite, vermehrte und neubearbeitete Auflage, mit vierzehn Abbildungen. München und Leipzig: Druck und Verlag von R. Oldenbourg. 1890. London: H. Grevel and Co., 33, King Street, Covent Garden.

LARGE 8vo. brochure, in paper cover, being part No. 1 of a work now in the press. It commences with an INTRODUCTION to the first edition, and this is followed by one to the second edition. The text covers 85 pages, and these are illustrated by 14 wood engravings.

The work is sub-divided as follows:—1. The Cultivation of Yeast in the Service of Industry: 1. The introduction of pure and selected Yeasts in the Making of Beer, and the results arrived at. 2. The Manufacture of Pure Cultivated Yeasts. II. Observations on Varieties of Brewery Yeasts: 1. Means of recognising the Varieties of *Saccharomyces*. 2. Higher and Lower Yeasts. 3. Investigations of Varieties of Yeasts, which have been tried in practice. 4. The Variations. 5. Chief Results. III. The Practical Investigation of Beer in the Store Casks, with respect to its permanency.

**REPORT ON ANALYSES AND RESEARCH** conducted in 1886-1889 in the Central Chemical Laboratory of Italian Customs, under the Direction of Senator CANNIZZARO. Compiled by R. NASINI and V. VILAVECCHIA.

This report is dedicated, through Senator Cannizzaro, to the Queen of Italy. Its object is twofold; 1st, to give an account of the industrial and commercial methods, and for the tests and analyses of various goods, together with suitable trade notices to serve as a guide to chemists engaged in analytical work connected with the tariff; and 2nd, to give a description of simple analytical methods and their interpretation, for the instruction of Custom house officials. Some of the analytical methods have been specially devised by the compilers for the exigencies of their work, while others are modifications and simplifications of those already in practice. In the latter case full references are given to scientific memoirs, text-books on commercial analysis, and reports of various congresses. Special attention is given to the criteria adopted by the Direction for the classification of samples under dispute. Reference is also made to certain investigations which are being carried on in the laboratory, especially upon the sophistication of salt, glucose, and spirits, the tariffs on acetic acids, as also on tobaccos in relation to the soil in which they are cultivated in Italy. These investigations will form the subject of special publications from the laboratory.

The report is divided into chapters and sections arranged according to the various categories of the tariff. A description, with plans of the laboratory, is given in the preface.

(See various sections of the Journal and Patent Literature and the Trade Report of this issue.)

**ERRATUM.**—This Journal, 1890, 980, "New Books" column 1, for "*Endiometry*" read "*Endimetry*."

Lead pipe and lead shot	Lb. 0'01½
Lead and all manufactures of lead not otherwise specified	30 % <i>ad val.</i>
Nickel anodes	10 % <i>ad val.</i>
Tinware and manufactures of tin not elsewhere specified.	25 % <i>ad val.</i>
Tin crystals	20 % <i>ad val.</i>
Zinc chloride, salts and sulphate of	5 % <i>ad val.</i>
Zinc, manufactures of, not elsewhere specified	25 % <i>ad val.</i>
Cement, burnt and unground.	100 lb. 0'07½
Cement, hydraulic, or water lime, ground, including barrels	Barrel 0'40
Cement in bulk or in bags	Bushel 0'09
Cement, Portland or Roman, shall be classed with all other cement at specific rates as above provided.	
Water limestone or cement stone	Ton of 13 cub. ft. 1'00
Coal tar and coal pitch.	10 % <i>ad val.</i>
Plaster of Paris or gypsum, ground, not calcined	100 lb. 0'10
Plaster of Paris, calcined or manufactured, 15 cents per 100 lb. or 45 cents per barrel of not over 300 lb.	" 0'15
Pimblago.	15 % <i>ad val.</i>
Do., all manufactures of, not otherwise specified.	30 % <i>ad val.</i>
Saltpetre	20 % <i>ad val.</i>
Asbestos, in any form other than crude, and all manufactures thereof	25 % <i>ad val.</i>
Celluloid, moulded into sizes for handles of knives and forks, not bored or otherwise manufactured; also moulded celluloid balls and cylinders coated with tin foil or not, but not finished or further manufactured	10 % <i>ad val.</i>
Fireworks	25 % <i>ad val.</i>
Blasting and mining powder	Lb. 0'03
Canister powder in pound and a half tins	" 0'15
Cannon and musket powder in kegs and barrels.	" 0'04
Giant powder, duxin, dynamite, and other explosives in which nitro-glycerin is a constituent part	" 0'05 and 20 % <i>ad val.</i>
Gun, rifle, and sporting powder in kegs, half kegs, or quarter kegs, and other similar packages.	Lb. 0'05
Nitro-glycerin	" 0'10 and 20 % <i>ad val.</i>
Electric arc light carbons or carbon points not exceeding 12 in. in length 2 dols. 50 cents per 1,000, and in proportion for greater or less lengths.	1,000 2'50
Oil, spermaceti, whale and other fish oils, and all other articles the produce of the fisheries, not specially provided for.	20 % <i>ad val.</i>

*Exemptions.*—The following articles are exempt from Customs duty:—

Ambergris.	Pelts, raw.
Bones, crude, not manufactured, burned, calcined, ground, or steamed.	Skins, undressed, dried, salted, or pickled.
Bone-dust and bone-ash for manufacture of phosphate and fertilisers.	Celluloid xylonite or xyolite in sheets, and in lumps, blocks, or balls, in the rough.
Guano and other animal and vegetable manures.	Ammonia, sulphate of.
Hides, raw, whether dry, salted, or pickled.	Sal-ammoniac.
	Aloes, ground or unground.
	Alum, in bulk only, ground or unground.

CUSTOMS TARIFF OF CANADA—*cont.*

Alumina or aluminium and alumina and chloride of aluminium or chloralum, sulphate of alumina and alum cake.

Antimony, not ground, pulverised, or otherwise manufactured.

Arsenic.

Argals or arzols, not refined.

Cream of tartar, in crystals.

Borax, ground or unground, in bulk of not less than 25 lb. only.

Boric acid.

Brimstone, crude, or in roll or flower.

Sulphur in roll or flower.

Bromine.

Cherry heat welding compound.

Cinnabar.

Cobalt, ore of.

Ashes, pot and pearl, in packages of not less than 25 lb. weight.

Kainite or German potash salts for fertilisers.

Potash, German mineral.

Potash, muriate and bichromate of, crude.

Soda, sulphate of, crude, known as salt cake.

Soda ash, caustic soda in drums, silicate of soda in crystals or in solution, bichromate of soda, nitrate of soda, or cubic nitre, salsoda, sulphide of sodium, arseniate, binarsenate, chloride and stannate of soda.

Iodine, crude.

Litbarze.

Manganese, oxide of.

Phosphorus.

Sulphate of iron (copperas), and sulphate of copper (blue vitriol).

Ultramarine blue, dry or in pulp.

Verdigris, or sub-acetate of copper, dry.

Whiting or whitening, gilders' whiting and Paris white.

Dragon's blood.

Musk, in pods or in grains.

Oxalic acid.

Quinine, sulphate of, in powder.

Aniline dyes and coal-tar dyes, in bulk or in packages of not less than 1 lb. in weight, including alizarin and artificial alizarin.

Aniline oil, crude.

Aniline salts and arseniate of aniline.

Annato, liquid or solid.

Annato seed.

Barilla.

Berries for dyeing or used for composing dyes.

Cochineal.

Dyeing or tanning articles, in a crude state, used in dyeing or tanning, not elsewhere specified.

Iron liquor, solution of acetate of iron for dyeing and calico printing.

Red liquor, a crude acetate of aluminium, prepared from pyroigneous acid, for dyeing and calico printing.

Extracts of logwood, fustic, oak, and of oak bark.

Indigo.

Indigo auxiliary or zine dust.

Do, paste, and extract of.

Lac dye, crude, seed, button, stick and shell.

Varnish, black and bright, for ships' use.

Cacoutheou, unmanufactured.

India-rubber, unmanufactured.

Rubber, crude, and hard rubber in sheets, but not further manufactured.

Recovered rubber and rubber substitute.

Gutta-percha, crude.

Madder and munjeet, or Indian madder, ground or prepared, and all extracts of.

Persis, or extract of arehail and cudbear.

Terra Japonica, gambier or cutch.

Turmeric.

Chloride of lime.

Colours, metallic, viz.: Oxides of cobalt, zinc, and tin, not elsewhere specified.

Ores of metals of all kinds.

Gypsum, crude (sulphate of lime).

Asphalt and bone pitch, crude only.

Clays.

Fire-clay.

Pipe-clay, unmanufactured.

Fullers' earth.

Cryolite.

Bismuth, metallic, in its natural state.

Copper, in sheets or plates of not less than 4 in. in width.

Precipitate of copper, crude.

Nickel.

Quicksilver.

Silver, German silver, and nickel silver, rolled or in sheets.

Spelter, in blocks and bars.

Tin in blocks, pigs, bars, and sheets, and plates and tinfoil.

Yellow metal, in bolts, bars, and for sheathing.

Zinc, in blocks, pigs, and sheets.

Cinchona bark.

Hemlock bark.

Oak bark.

Tanners' bark.

Cannwood and sumac and extract for dyeing or tanning purposes, when not further manufactured than crushed or ground.

Nut galls.

Litmus and all lichens, prepared and not prepared.

Alkanet root, crude, crushed, or ground.

Root, medicinal, viz.:—aconite, columba, ipæacuanha, sarsaparilla, squills, taraxacum, rhubarb, and valerian.

Gums, viz.:—amber, arabic, Australian, copal, dammar, kaurie, mastic, sandarac, Senegal, shellac; and white shellac in gum or flake, for manufacturing purposes; and gum tragacanth, gum goida, and gum tarberry.

Resin or rosin, in packages of not less than 100 lb.

Turpentine, raw or crude.

Foot grease, being the refuse of cotton seed after the oil has been pressed out, but not when treated with alkalis.

Oil cake and oil-cake meal, cotton-seed cake and cotton-seed meal, and palm-nut cake and meal.

Oils, viz.:—Cocoanut and palm in their natural state; ottar or attar of roses and oil of roses.

Blood albumen, tannic acid, antimony salts, tartar emetic and grey tartar, when imported by manufacturers for use in their factories only.

Chlorate of potash in crystals, when imported for manufacturing purposes only.

Esparto or Spanish grass, and other grasses, and pulp of, for the manufacture of paper.

Platinum wire, and retorts, pans, condensers, tubing, and pipe made of platinum, when imported by manufacturers of sulphuric acid for use in their works in the manufacture or concentration of sulphuric acid.

White shellac, for manufacturing purposes.

—Board of Trade J.

## RUSSIA.

*Chemicals in Russia.*

It is said that the new Russian Customs tariff, which is to come into force in July 1891, and is now being drafted by a commission sitting in St. Petersburg, will be particularly severe on chemical products. The duties on these goods will be advanced in an unprecedented manner, and no loopholes will be left by which it will be possible to import them at lower rates under other denominations.—*Chemist and Druggist.*

## MISCELLANEOUS TRADE NOTICES.

## THE OUTPUT OF PLATINUM.

In view of the recent enormous advance in the price of platinum, the following figures, showing the output of the crude ore in Russia, are of interest:—In 1881 2,986 kilos.; were produced; in 1882, 4,081 kilos.; in 1883, 3,537 kilos.; in 1884, 2,237 kilos.; in 1885, 2,591 kilos.; and in 1886, 4,317 kilos., or an average of hardly 660 cwt. a year. All this platinum is found in two districts of the Government of Perm. The mines of Goroblagodsk yield about two-thirds, those of Nigi-Tagnitsk one-third of the supply. The syndicate which is said to be cornering the platinum supply have, no doubt, in view the enormously growing demand for platinum for electric industries, but the cut-throat policy they are reported to pursue is likely to have the effect of stimulating the working of platinum deposits in other parts of the world, as well as putting electricians on their mettle in finding a substitute for platinum. In the Oural mines, until some years ago, platinum was obtained as a kind of by-product in the working of the auriferous deposits the existence of which led to the opening of these mines. But during the last few years the gold ore has become much scarcer, and platinum has superseded gold as the principal product of the mines. Besides the operations of the syndicate, the recent advance in the metal is attributed partly to the increasing scarcity of the ore and to the fact that labour, always an uncertain factor in the Oural mines, has become excessively scarce since the commencement of the Trans-Siberian railway. According to later advices, the whole of the platinum which will be produced in the Oural mines for the next 10 years has been sold in advance to certain foreign companies. Owing to these contracts the price of platinum has advanced from 2,500 to 12,500 roubles per pood. News comes opportunely from Mexico of the discovery of platinum in the ores extracted from certain mines in Sinaloa, a State famous for its mineral wealth.—*Chemist and Druggist.*

## THE MINERAL WEALTH OF CANADA.

It is fully established that Canada is rich beyond compare in all the more useful minerals, and that she possesses deposits of nickel, silver, and other ores of great extent. The Dominion has coal and iron in close proximity to each other on both her seaboard, and in each instance the fuel and the ores are of the highest qualities. In Nova Scotia there are, within six miles of the Atlantic, huge deposits of fine ironstone alongside pure limestone, and with coking coal in seams 30 feet thick. It is in this part—most probably in Pictou county—that the cheapest and best pig iron in the world will be made at no distant date, and it may be that from the Nova Scotian blast-furnaces, built and run by British capital, we shall at some future date derive a large proportion of our supplies of imported iron. Situated close to the sea, and with proper shipping facilities, these great mineral deposits have a future which is indubitable, and they are sure to attract capital and skill before many years have elapsed. In the Sudbury district the deposits of nickel ore are only just being opened up, but they have a bright future, not only because nickel is likely to be largely used as an alloy with steel, but because nickel itself possesses intrinsic merits which will ensure its free use so soon as it can be sold at reasonable prices and

in quantity. In the Algoma district of Lake Superior there are great deposits of copper ore—stated by Mr. Erastus Wiman to be at least twenty-five times as extensive as those of the Calumet and Hecla district on the American side of the lake. There is also silver in rich lodes and platinum in unusual quantities. Further west, in British Columbia, the mineral deposits are vast and varied. They include gold, silver, lead, iron, and coal, and exist in quantities not yet fully ascertained or appreciated, but known to be exceedingly great. On the Pacific coast, in Puget Sound and elsewhere, the deposits of iron ores and coal are on a tremendous scale, both being very high in quality, and so close together as to render it most easy and economical to carry on blast-furnace work.—*Ironmonger*.

#### THE UNITED ALKALI CO. (LIMITED).

This is the title under which the Chemical Union has been registered by a Liverpool firm of solicitors. The capital of the concern is 6,000,000*l.*, half in preference and half in ordinary shares of 10*l.* each. The first subscribers comprise the following, nearly all well known in the chemical trade:—J. Brock, Widnes; H. Gaskell, Widnes; J. K. Huntley, Flint; C. Wigg, Liverpool; J. H. Dennis, Liverpool; A. W. Allhusen, Gateshead; J. E. Davidson, Newcastle-on-Tyne; G. E. Barlow, Widnes; J. C. Stevenson, M.P., South Shields; J. Tennant, Saltwell, Gateshead; G. L. Wigg, Runcorn; P. J. Worsley, Bristol; J. A. E. Rayner, St. Helen's; E. K. Muspratt, Dale Street, Liverpool; W. J. Menzies, St. Helen's; H. Gaskell, jun., Widnes; R. Shaw, Widnes. The company also possesses in addition to its ordinary directors, one honorary president (Sir Charles Tennant) and four honorary vice-presidents, Sir E. Sullivan, and Messrs. H. Gaskell, J. K. Huntley, and J. H. Dennis. The qualification of each of these officers is holding 5,000*l.* shares in the company. Besides the honorary officers, who are directors *ex officio*, the board is to consist of from 9 to 20 directors, the first being: Messrs. John Brock, Chairman; Chas. Wigg and J. C. Stevenson, M.P., vice-chairmen; Thos. Alexander, Glasgow; A. Allhusen, C. E. Barlow, E. Baxter, J. E. Davidson, H. Gaskell, jun., Jas. Gaskell, W. J. Menzies, E. K. Muspratt, G. Pilkington, J. A. E. Rayner, R. Shaw, James Tennant, G. L. Wigg, and P. J. Worsley. Their qualification is 1,000*l.* The remuneration of the chairman is 2,500*l.*, with a further 500*l.* after 8 per cent. dividend on the ordinary shares; that of each of the other directors is 400*l.*, one half of which shall be paid irrespective of the number of attendances at board meetings, and the remainder to be decided at the end of the year according to the number of their respective attendances. The objects of the company are described as follows:—To carry on business as manufacturers of chemical products and drugs of all kinds and in all branches of such business; as colliery owners and rock-salt proprietors, miners, brine owners, and white salt manufacturers; as dyers, drysalts, and manufacturers of dyes, stains, colours, varnishes, paints, and pigments; as manufacturers of manure, soap, paper-pulp, paper grass, bricks, pottery, terra-cotta, and sanitary and disinfecting preparations, coke, cement, and artificial stone; as waterproofer, and india-rubber and leather manufacturers; as millwrights, makers of locomotive engines, waggons, and rolling stock, stone and limestone quarry proprietors, lime-burners, owners of mines of all descriptions, and winners and workers of minerals and mineral oils, and the business of preparing mineral substances for sale or for treatment in manufacturing processes; as metallurgists in all branches; to manufacture and supply gas to the property of the company or the neighbourhood, and, in connexion therewith, to carry on the business of a gasworks company; to carry on any business directly or indirectly connected with the generation, accumulation, distribution, supply, or application of electricity.

#### EXPORTATION OF CUBAN MANGANESE.

It is announced that during the month of August, 5,200 tons of manganese were exported from St. Jago de Cuba. Owing to the ready sale the manganese meets with in the

United States its production is fast increasing, and the exports for September will be larger than ever before. The owners of the mines have formed a syndicate to work themselves, some American companies which first undertook to work the mines having failed to fulfil their contracts. The exports of manganese ore from 1st July 1889 to 30th June 1890, amounted to 2,240 tons, and from 1st July to 20th August 1890, to 4,190 tons. In other words, the Cuban syndicate exported more in 51 days than American contractors did in one year.—*Chemical Trade Journal*.

#### THE TRADE IN SULPHURIC ACID IN TURKEY.

According to the Belgian *Bulletin du Musée Commercial*, for October 4th, there is at present but a relatively unimportant import of sulphuric acid into Constantinople. In Turkey, as elsewhere, the trade in this article is in direct proportion to the development of the industries which make use of it. The manufacture of mineral waters, the dye-works, the cloth factories belonging to the State, the electrical offices, such as telegraphs, fortifications, marine, and the jewellers' workshops are the principal clients. The annual consumption amounts to about 40,000 kilos, net, the value being about 2,000*l.*

The Custom house administration makes no distinction between nitric acid and sulphuric acid, and returns general figures which make it impossible to give more than a roughly approximate division. The following table gives the amounts of sulphuric and nitric acid imported into Constantinople and into the other parts of the Ottoman Empire in the course of the year 1888—89:—

From	To Constantinople	Import Duties.	Other Parts of the Empire.	Import Duties.
	Kilos.	Piastres.	Kilos.	Piastres.
England .....	..	..	2,186	210
Austro-Hungary .....	3,963	521	13,832	2,116
Italy .....	..	..	58	21
Bulgaria .....	..	..	80	37
Tunis .....	..	..	510	59
Servia .....	..	..	64	14
France .....	88,220	7,193	42,751	4,299
Greece .....	..	..	30	9
	92,222	7,714	59,511	6,765

About four-fifths of the total importation concern sulphuric acid, of which 10,000 kilos are used in the Imperial factories at Stamboul, Makrikeni, and Ismidt. Most of the sulphuric acid brought into Turkey comes from Marseilles, notably from the Rio Tinto Company and from the Saint Gobain factory. A certain important proportion of the consumption is indirectly supplied by England and Germany, through agents in London and Hamburg. For some little time past a house at Antwerp has been sending small quantities of sulphuric acid to Constantinople. The importation by way of Trieste and Galatz, from the Black Sea, is much less than it was.

Steamers are apt to refuse to take large cargoes of this article, as being dangerous. There is therefore serious difficulty in importing it from London and Hamburg, as most of the steam navigation companies now decline to carry inflammable articles. If, however, they do consent to take sulphuric acid on board, it ought to be highly insured, as such articles are thrown overboard at the least threat of danger. The Austro-Hungarian Lloyd has a limit of 15 cases, beyond which it will accept no consignment of this acid. Sailing vessels are much more accommodating and their freight is lower.

## REPORT ON ALKALOIDS.

*Report of the Central Laboratory of the Italian Customs Department, 339—341.*

According to the tariff, alkaloids are distinguished as "quinine salts, and alkaloids not specified and their salts;" both classes pay 12 lire per kilo. These are distinguished from medicinal extracts, which pay 120 lire per quintal, and are defined as follows:—"Medicinal extracts, liquid as well as solid, such as the extracts of aconite, monkshood, juniper, &c. &c., and such other herb, root, flower, wood, and fruit appertaining to pharmacy."

Among substances sent to the laboratory was phenacetine, used medicinally as an antipyretic and antineuralgic; though strictly speaking this substance is not an alkaloid, yet as the tariff report classes antifebrine (acetanilide) among the alkaloids, phenacetine must also be included in the same category. A sample of quinidine was classed as a quinine alkaloid, and one of pyridine as an unspecified alkaloid.

—V. H. V.

## REPORT ON MEDICINAL SUBSTANCES.

*Report of the Central Laboratory of the Italian Customs Department, 349—352.*

Among the substances declared under the category of medicines (duty, 10 lire per quintal, tariff No. 61) were samples of thymol, sawdust soaked with corrosive sublimate, and quinol, which the laboratory decided were rightly classed as medicines "specified and not specified." Their decision on quinol was based upon a verdict given in the case of resorcinol. Another importation declared as earbolic acid was found to consist of the substance known commercially as creoline; this was the subject of a Ministerial decree (February 25, 1889), as follows:—"The Minister, considering that creoline is used as an antiseptic, and as regards its therapeutic properties is to be classified among medicinal substances such as iodol, salol, and other similar products of analogous therapeutic property, decides, in accordance with the Consulting College of Experts, that creoline is to be classed with medicines not specified, and is subject to a duty of 10 lire per quintal. A decree of a similar kind was given (September 4, 1889) concerning the oil of the *Laurus cerasus*, "used exclusively in veterinary practice."—V. H. V.

## REPORT ON MINERALS, METALS, &amp;c.

*Report of the Central Laboratory of the Italian Customs Department, 405—411.*

The tariff classifies, under the generic title of metallic minerals, substances obtained from the surface or interior of the earth which serves as the first materials for the preparation of industrial metals such as iron, zinc, copper, lead, antimony, tin, &c. Such minerals are free of import duty, but on exportation pay 22 lire per ton of lead minerals, 2.20 lire for copper, and 5.50 lire for zinc. Scoriae of metallic minerals are free both of export and import duty.

The report also distinguishes between "natural oxide of manganese" classed with "minerals of all sorts" and "prepared oxide of manganese," which is subject to the same duty as the oxides of iron and lead.

In the former case the oxide is free of duty, in the latter it pays 4 lire per quintal. The Direction point out that though it is not difficult for a practised chemist to distinguish between a natural and a prepared oxide of manganese, yet this problem is beyond a Custom house official. Mention is made of certain disputed samples.

As regards antimony, the report distinguishes between the metal which pays 8 lire per quintal, "antimony sulphide," also called "crude antimony," which pays 4 lire per quintal, and metallic alloys of lead and antimony, and of lead, antimony, and tin classed under the sections 214a and 215a. Disputes have arisen on these points. Again, the report states that "spiegeleisen" occurs sometimes in a faceted form and sometimes in acicular bundles of a various iridescent colour; it should not contain more than 30 per cent. of manganese. Beyond this limit it is to be

classed among metallic alloys not specified. In the latter case it pays 5 lire per quintal for the crude state and 100 lire per quintal for the manufactured articles. The Direction of the laboratory do not agree with the distinction drawn by Ledebur (Die Metallurgie, vol. 290) between spiegeleisen containing less than 25 per cent. of manganese and ferromanganese containing more than 25 per cent.; the former shows a characteristic fracture consisting of regular lamellae and of a silver-white colour, which is made up of small prisms of rhombohedral system, while the fracture of the latter is completely granular. It is pointed out that these distinctions are not valid, and for the decision in case of disputed samples the Direction adopted the process proposed by Volhard, confirming their results by those of Kessler or Pattinson.

Controversies also arose concerning various manufactured articles, especially those which were supposed to contain silver or gold. Thus certain gilded tea-trays were found to be gilded with alloy of tin and lead. Certain spectacles supposed by the Custom house officials to be covered with silver, did not contain this metal but only tin, though other spectacles declared as gilded silver were composed entirely of gold.—V. H. V.

## REPORT ON ANIMAL AND IVORY BLACK.

*Report of the Central Laboratory of the Italian Customs Department, 381—385.*

Under this heading the tariff includes bone-black, lamp-black, and other blacks prepared by the carbonisation of wood, tar, &c.; the first named pays 50 lire, and the last 5 lire per quintal. Residues, however, from sugar refinery, and residues of animal black, are classed as "concime" (refuse), and are then free of duty. According to the instructions it is necessary to distinguish between lamp- and bone-black; the Direction, therefore, determines the amount of ash, the power of absorbing colouring matters, and the amount of volatile matters by calcining in a porcelain crucible in a current of hydrogen (Köhler, Die Fabrikation des Russes und der Schwärze, 102).

## IMPORTATION INTO ITALY OF CHEMICAL PRODUCTS NOT SPECIFIED IN THE CUSTOMS TARIFF.

*Report of the Central Laboratory of the Italian Customs Department, 343—349.*

In this report an account is given of attempted frauds on the Italian Customs, some few of which are selected. A consignment labelled "concime" (refuse), and thus free from duty, was found to consist principally of naphthalene, which is a substance specially mentioned among the unclassified chemicals. A double oxalate of potassium and antimony was introduced as tartar emetic, iodoform as picric acid, silver nitrate as caustic potash, chloral as sodium sulphate, santonine as boric acid, magistery of bismuth as calcium phosphate, reduced iron as antimony sulphide, and ealomal as corrosive sublimate.

Frequently mixtures intended for the manufacture of fireworks were declared among the unspecified chemicals, and not as explosive matters. Examples are given of mixtures of barium nitrate and resin and eye-straw containing some nitro product which is used for the preparation of a certain kind of dynamite.—V. H. V.

## NOTES FROM BAKU.

Chem. Zeit. 14, 1330.

It is reported that a large quantity of platinum ore has been found in the neighbourhood of Werchoturje, near Jekaterinenburg. An increase in the duty on imported soda is expected, and consequently the price of soda in Russia has already experienced a rise. The Minister of Finance has received a deputation representing the Baku naphtha industry, which urged (1) that those Imperial lands that produce naphtha shall be "free" in order to increase the production of the raw material and lower the price; (2), that the rate of freight shall be lowered on the Baku-Batoum railway; (3), that a duty shall be placed on all exported raw naphtha oil.—J. W. L.

## THIRTEENTH MEETING OF THE SOCIETY FOR PROTECTING THE INTERESTS OF GERMAN CHEMICAL INDUSTRY.

(Chem. Ind. 1890, 13, 403—430.)

The chemical industry of Germany, which has been constantly improving for several years, has made further progress during the past year, owing to the fact that the volume of trade was considerably greater than in the preceding year. No great profit was made by the rise in prices which took place in several branches, this being counter-balanced by higher wages and higher prices of materials, especially coal. The number of chemical establishments was 4,809, against 4,464 in the previous year; and 90,585 workpeople were employed, against 84,315, an increase of 7.44 per cent. This corresponds to a total of 27,379,200 working days, against 25,100,024 in 1888; and 71,611,050 marks wages against 65,644,013 in 1888. The average wages increased from 773 to 783 marks. Another indirect proof of the progress of German chemical industry is an increase of 147,000 tons in the imports of raw materials for the production of chemical products; whilst the export of such raw materials was reduced by 29,000 tons. The price of exported chemicals was about 10 per cent. higher than in the preceding year (561 marks per ton against 508 marks), and the increased production was not due to larger export, but to an increased home demand. In 1889 the number of chemical establishments carried on by limited companies was 85, and these, on a capital of 188,203,600 marks, earned 19,922,168 marks in dividends equal to 10.58 per cent. (compare this Journal, 1890, 121).

The average dividends paid since 1882 by limited companies manufacturing chemical products were as follow:—

	Per Cent.
1882 .....	12.82
1883 .....	10.02
1884 .....	7.96
1885 .....	6.37
1886 .....	7.17
1887 .....	8.92
1888 .....	9.78
1889 .....	10.58

In the different industries the results were as follow:—

## ALKALI INDUSTRY.—The average dividends were:—

	Per Cent.
1885 .....	5.86
1886 .....	6.06
1887 .....	6.95
1888 .....	7.71
1889 .....	7.44

The slight decrease in 1889 was due chiefly to a falling off in the export of *Stassfurt salts*. The quantity of kainite obtained at Stassfurt last year was 324,500 tons, against 318,500 tons in the previous year, but the other salts showed a decrease from 916,750 to 861,300 tons. The Stassfurt industry used:—

	Tons.
Carnallite .....	769,947
Kainite .....	69,700
Sylvanite .....	15,883
Schoenite .....	41,917

and manufactured from these:—

	Tons.
Potassium chloride .....	123,748
Potassium sulphate .....	6,221
Calcined potassium—magnesium sulphate .....	9,215
Crystal potassium—magnesium sulphate .....	671
Chemical manures .....	2,238
Calcined kieserite .....	31,824

The *Potassium Industry* showed no progress during last year. This was due, partly to the introduction of smokeless powder, partly to the competition in potash manufacture, and partly to the low prices of potassium chlorate. The *Soda Industry* much improved, although costs were considerably higher, owing to the higher prices of coal and raw

materials; but a large demand stimulated sales, and it is hoped that the English "Chemical Union" will have the effect of steadying the prices in the German soda trade. The use of hydrochloric acid decreased during the last year, more sulphuric acid being used instead. The bleaching powder manufacture was very unfavourably influenced by the collapse of the English convention.

The *COAL-TAR COLOUR INDUSTRY* showed much more progress, as the following average dividends indicate:—

	Per Cent.
1885 .....	7.05
1886 .....	9.94
1887 .....	13.25
1888 .....	15.44
1889 .....	17.50

The higher profits were due chiefly to the increased production. Many new colouring matters, some of great value, were manufactured, and the chemistry of the azo-compounds showed especial progress. This was the case too with alizarine colours, the export of which was higher by 1.7 millions of marks than in the previous year.

*PHARMACEUTICAL, PHOTOGRAPHIC, AND OTHER TECHNICAL CHEMICALS* gave the following average dividends:—

	Per Cent.
1885 .....	10.13
1886 .....	10.60
1887 .....	12.50
1888 .....	8.90
1889 .....	9.00

The diminution in the last two years was caused by higher prices of raw materials and reagents (soda, sulphuric acid, &c.) as well as by a rise in wages and keen competition. Pharmaceutical substances suffered a further disadvantage, in that many new articles manufactured were of little therapeutical value, and disappeared after a short trial, while others were required in such a state of purity that their manufacture could not possibly pay. A considerable increase however in the export of fine chemicals took place, the export of alkaloids alone increasing by 1½ millions of marks. *Alcoholic Substances* are still suffering from the new brandy taxation bill. The manufacture of *Inorganic Colouring Matters* has made good progress in spite of competition. The exports of copper and lead colours, zinc white and zinc sulphide showed an increase, and even the ultramarine trade, which has been in an unsatisfactory state for some time past, improved a little, as the dividends show a rise of from 1.38 to 2.04 per cent., and it is hoped that this progress will continue, as the manufacture is now syndicated, thus putting an end to unsound competition.

The *SOAP INDUSTRY* suffered greatly from the increased prices of raw materials, this increase being due partly to the import of cattle being prohibited. Competition has however been regulated by a number of conventions which were formed in the last two years in different parts of Germany.

The trade in *EXPLOSIVES* showed the following dividends:—

	Per Cent.
1885 .....	10.65
1886 .....	16.09
1887 .....	14.08
1888 .....	15.41
1889 .....	13.00

The reason that last year's dividend was lower than in the three previous years was due to the leading dynamite establishments having formed a so-called "cartel" with several powder mills. The result, however, was unsatisfactory to the dynamite trade; but the trade will probably succeed better in the current year. The trade in *nitro-glycerin explosives* was not bad, there being more competition and also a greater demand than hitherto, and the prices were better than in 1888, while the export was large. In *percussion-cap manufacture* small profits were the rule, owing to sharp competition produced by the opening of three new establishments. The convention for protecting the trade in *blasting powder* was not renewed, and the result was that prices receded considerably, leaving hardly

any profits. The invention of the new smokeless powder, and its introduction into the different armies, had of course a very bad influence upon the trade in ordinary gunpowder. *Gun-Cotton* will probably be only in temporary demand, as the various Governments are anxious to manufacture their own article, and to become as independent as possible of private industry.

The ARTIFICIAL MANURE TRADE showed the following average dividends:—

	Per Cent.
1885 .....	3'14
1886 .....	2'41
1887 .....	5'14
1888 .....	7'97
1889 .....	9'98

This improvement, chiefly due to the splendid results obtained by the experimental stations ("Versuchsstationen") caused a general inquiry for artificial manures and a rise in superphosphate prices; but it is feared that this improvement will not last.

The above-mentioned progress in the different branches of the German chemical industry is further shown by the fact that during the last year nine new limited companies were formed with paid-up shares of 10,100,000 marks, and the capital of ten other companies was increased by a total sum of 7,044,000 marks, whilst four other companies reduced their capital by 1,615,142 marks. The following figures show that notwithstanding the high average dividends of the last year, a considerable number of establishments yielded no profits, or hardly any.

The total number of German chemical establishments was 85.

Twenty-four of these, or 28·23 per cent. of the whole, yielded no profits at all.

Four, or 4·71 per cent., divided 2½ per cent.

Seven, or 8·24 per cent., divided from 2½ to 5 per cent.

Eight, or 9·41 per cent., divided from 5 to 7½ per cent.

Twenty-two, or 25·88 per cent., divided from 7½ to 10 per cent.

Thirteen, or 15·29 per cent., divided from 10 to 15 per cent.

Seven, or 8·24 per cent., divided more than 15 per cent.

Compared with previous years, the progress of the last two years is striking, as the following table shows:—

Year.	No Dividend.	Under 5 per Cent. Dividend.	5 to 10 per Cent. Dividend.	Over 10 per Cent. Dividend.
	Per Cent.	Per Cent.	Per Cent.	Per Cent.
1885	34	22	28	16
1886	38	24	18	20
1887	38	12	30	20
1888	32·5	16·25	26·25	25
1889	28·23	12·95	35·29	23·53

(Compare this Journal, 1890, 121.)

The proposed alterations of the GERMAN PATENT LAW, as published in a bill (see *Reichsanzeiger*, March 17th, 1890), were investigated by a Commission, which reported favourably on its main features. The main features in these alterations, are: Firstly, it has not been thought advisable to give an exact definition of what is called a patentable invention, the decision being left in each case to science and law. The position of chemical inventions in this respect will be seen below. Secondly, for some time past it has been uncertain how far a German patent for a chemical process protected the products manufactured by that process, and inventors suffered considerable loss by chemical products imported which had been manufactured in foreign countries by processes patented in Germany. In 1886, and again in 1888, this importation was declared illegal; but to remove all doubt it is proposed to add a clause to the new Patent Law Bill, to the effect that nobody shall be allowed to import into Germany and sell therein chemical products

manufactured in other countries by processes patented in Germany, unless the special permission of the patentee has been obtained. Further, that *novel* chemical products are to be regarded as having been manufactured by the said processes, unless otherwise proved. Thirdly, the bill also contains the clause that, if a new process is patented, all products manufactured by this process are likewise protected. As this definition is rather vague, and may cause considerable trouble and uncertainty, it is proposed to change the clause to the effect that all products *directly* obtained by patented processes are protected by the patents. Fourthly, by the new bill not only mechanical apparatus, but also the technical use of new chemicals, dyeing materials, &c. will be within the sphere of the patent law. It is therefore hoped that chemical inventions will greatly benefit by the firmer control which will thus be possible. Fifthly, hitherto it has been necessary for the German inventor to prove that a new chemical product has been manufactured by his patented process if he wishes to prevent its import from a foreign country. In many instances this is either extremely difficult or altogether impossible; and it is therefore proposed that in future no such product should be imported, unless it is proved by the importer that it has been manufactured in a different way. Another proposal, with the same object, is to grant patents not only for new chemical processes, but also for such chemical products manufactured by these processes as are entirely new. But as soon as these products are proved to have been manufactured by other methods they may be freely sold anywhere. Also, by this second proposal, German inventors would be well protected against foreign import, without being subjected to such restrictions as might prevent progress. The bill proposed by the Government is however not favourable to either of these proposals, owing to foreign competition being considered too unimportant in this direction. Sixthly, it is proposed that the new patent law should contain a precise definition of what is termed a "special chemical process" as follows:—A special chemical process is the application of one or several combined chemical reactions, in order to obtain a special industrial purpose by certain means or analogous ones which may be substituted for them. It follows from this definition that for every patent application a clearly defined description of the whole process, from beginning to end, is required. Substances or methods which can plainly be substituted for others need not be specially mentioned in the patent specifications. Seventhly, in view of all these points, the Commission recommends the following clause:—If a patent for a special chemical process is granted, the corresponding chemical products shall be regarded as being manufactured by this process, unless otherwise proved.

The bill further intends to define clearly the authority of the Patent Office concerning the granting of patents, as follows:—(a.) If the examination by the Patent Office authorities shows that the invention is not new, the patent must be refused. (b.) If an invention is found to be partially new, the relations of the previous to the subsequent patents have in every case to be defined as clearly as possible, so that the value of the former patents is not affected. (c.) If two patents are found to be totally or partially equal, the Patent Office shall, according to the proposed new bill, be entitled to declare the second totally or partially void, whilst under the existing law no remedy is possible if the second patent has been granted before the publication of the first. (d.) The existing examination of patent applications in the German Patent Office has long been found insufficient, owing to the enormous amount of labour connected therewith. It has often been remarked that it would be much simpler to let time and competition decide the value of patents, many of which are always perfectly valueless. The difficulties in examining the patent applications are especially great in patents referring to chemical industry. But on the other hand the chief object of the Patent Office is not to eliminate valueless applications, but to promote valuable inventions. A reorganisation in this direction which is recommended by the new bill, requires firstly that in future patent applications shall be examined exclusively by especially selected authorities of the central office, and, secondly, that the department for appeals which

is at present united with the application department, shall be entirely separate from it. Thirdly, appeals shall be verbal, if requested by one of the parties. Such verbal discussions would be a most valuable guarantee for the correctness of the final decisions of the Patent Office, especially with reference to chemical processes, if no models, drawings, &c., can be given.

The above-mentioned features of the new Patent Bill will doubtless exert an influence for good upon the chemical industry of Germany; but it cannot be overlooked that the bill also has drawbacks and omissions. The first of these is, there is no sufficient provision for protecting the inventor by granting him patents which had been granted in error to others. Such patents are void, but the real inventor has no right to apply for the patent instead, and this is decidedly unfair. The Government is of opinion that nothing can be done until the introduction of the new Civil Code now in preparation. Secondly, errors in the official examination of patents can never be entirely excluded, even if the examination be made in the most minute and careful way. It is therefore wrong that there should be no appeal against the decision of the Patent Office, if an application is refused by mistake. Thirdly, it is proposed that foreign inventors should not be granted patents or patent rights in Germany, if their countries do not grant the same patent rights to German subjects as to the subjects of other countries. Such a clause must be most decidedly objected to, for while it would have no practical value, it would be sure to produce international friction.

In the further course of the meeting it was strongly urged that Germany should join the international union for the protection of industrial property. The right of priority for six or seven months in case of patent applications in the countries of the union would be a great boon for inventors compared with the present system; and in many cases it would then be very convenient to make a foreign application prior to the German one, owing to the great number of refusals (58 per cent. last year) of the German Patent Office. Germany's joining the union would further be a great advantage for the international regulation of the trade-mark question.—H. S.

### BOARD OF TRADE RETURNS

#### SUMMARY OF IMPORTS.

	Month ended 31st October	
	1889.	1890.
Metals.....	£ 1,735,623	£ 2,073,732
Chemicals and dyestuffs.....	560,897	458,458
Oils.....	753,432	636,067
Raw materials for non-textile industries.....	4,735,798	4,105,988
Total value of all imports ....	38,230,614	37,746,236

## Monthly Patent List.

\* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

### I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

#### APPLICATIONS.

16,679. W. H. Le Mesurier. Improvements in apparatus for refrigerating air, also applicable to the evaporation of liquids. October 20.

16,761. W. P. Thompson.—From A. Mason and J. Wilson, United States. Improvements in and appertaining to effecting and maintaining combustion in secondary chambers of boiler and other furnaces, and in apparatus therefor. Complete Specification. October 21.

16,881. J. F. Pease. Improvements in furnaces. Complete Specification. Filed October 22. Date applied for April 7, 1890, being date of application in United States.

16,924. M. Edgar and W. J. Warnock. Improvements in and relating to furnaces. October 23.

16,935. E. Edwards.—From J. Langheck, Germany. Improvements in furnaces. October 23.

16,940. L. C. Riggs. Improvements in refrigerating apparatus. Complete Specification. October 23.

17,113. W. Bireb. Improved apparatus for filtering sewage and other liquids. October 27.

17,117. D. Rylands. Improved means of manufacturing glass vessels and adapting the same for the storage and conveyance of compressed gases, and for similar purposes. October 27.

17,218. J. Zeller. Process for obtaining a new material from bituminous slate, and its application as a filtering medium, and as a colouring matter. October 28.

17,237. P. Callibures. An improved and completed system of apparatus for evaporation and distillation. Complete Specification. Filed October 28. Date applied for July 15, 1890, being date of application in France.

17,385. J. G. Galley. Improvements in apparatus for burning refuse, calcining ores or other substances, burning cement, and other purposes of the like kind. October 30.

17,446. R. Wood. Improvements in means or apparatus for filtering, more especially applicable in the manufacture of varnish and japan. October 31.

17,702. C. J. Copeland. Improvements in apparatus for feeding fuel to gas producers. November 4.

17,718. H. H. Lake.—From E. Bolton, United States. Improvements in distilling and condensing apparatus. Complete Specification. November 4.

17,815. F. Ellershausen. Improvements in reverberatory furnaces. November 5.

17,820. R. Gubbins. Improvements in retorts. November 5.

17,855. W. Blagg. Improvements in or appertaining to furnaces or heating apparatus for salt pans and other like purposes. November 6.

17,970. J. Donald. Improvements in charring or drying retorts. November 8.

18,050. T. Thorp. A new and improved apparatus for the clarifying of liquids. November 10.

18,099. T. P. Hinde. See Class XVII.

#### COMPLETE SPECIFICATIONS ACCEPTED.\*

1889.

17,938. J. G. Chamberlain and G. E. Davis. Apparatus for evaporation of liquids. November 5.

18,108. J. Ruseoe. Apparatus for charging and drawing retorts mechanically. November 19.

20,784. R. A. Robertson and W. J. Mirrlees. Apparatus for evaporating, concentrating, and distilling liquids. November 5.

20,954. J. Wright. Apparatus for distilling, evaporating, or concentrating liquids, &c. November 5.

1890.

210. T. Thorp. A frictionless metallic gas-pressure gauge. November 12.

398. W. Wild. Apparatus for evaporation of liquids. November 19.

828. A. Smith. Filters. November 19.

1239. D. Bethmont. Apparatus for instantaneous production of vapour from water or other liquids. November 12.

5419. Transferred to XV. and XVIII.—B.

6032. M. W. Dewey. See Class XI.

12,325. J. Jackson. Pressure and vacuum gauges. November 12.

13,084. C. J. Cario. Thermometers and pyrometers. November 19.

14,846. W. H. Kennedy. See Class X.

### II.—FUEL, GAS, AND LIGHT.

#### APPLICATIONS.

16,738. F. J. Jones. An improvement in the manufacture of coke and gas. October 21.

16,760. W. P. Thompson.—From A. Mason, United States. New or improved method of and apparatus for burning coal and hydrocarbon fuel. Complete Specification. October 21.

16,762. W. P. Thompson.—From A. Mason and J. Wilson, United States. Improvements in or relating to burning petroleum and other hydrocarbons, and apparatus connected therewith. Complete Specification. October 21.

16,846. F. E. Ross. Improved method of and apparatus for producing gases from bituminous fuel. October 22.

17,000. J. J. Thomas. Coal-gas generating apparatus. Complete Specification. October 24.

17,030. J. Lyon-Field. An improved manufacture of night-lights. October 24.

17,154. B. F. Field. Improvements in and relating to a process or mode of manufacturing fuel, and in and to the product obtained by said process. Complete Specification. October 27.

17,159. T. G. Springer. Improvements in the manufacture of gas. Complete Specification. October 27.

17,182. G. Love. Improved coke-oven doors. October 28.

17,183. J. F. Craddock. An improved fire-lighter. October 28.

17,201. L. Van Vestrout. Improvements in setting inclined carbonising or gas retorts. October 28.

17,287. W. Smith. Improvements in the manufacture of peat fuel and peat-moss litter. October 29.

17,321. J. Morris. The manufacture of an improved artificial fuel, and of briquettes. October 29.

17,466. H. H. Lake.—From The Standard Coal and Fuel Co., United States. A compound for treating fuel. Complete Specification. October 31.

17,470. H. H. Lake.—From The Standard Coal and Fuel Co., United States. An improved compound for treating fuel. Complete Specification. October 31.

17,484. H. H. Lake.—From The Standard Coal and Fuel Co., United States. An improved compound for treating fuel. Complete Specification. October 31.

17,710. W. Wren. Improvements in or additions to retorts such as are used in the manufacture of coal-gas. November 4.

17,745. T. Cooke. Improvements in the method of setting clay retorts for the manufacture of coal-gas, to be called "The Bristol Retort Setting." November 5.

17,921. C. Eidle. Machine for charging gas retorts. Complete Specification. November 7.

18,047. Unsworth and Richmond, Lim., and W. Unsworth. Improvements in material for use in incandescent gas fires. November 10.

18,115. S. Pointon. Improvements in apparatus connected with the manufacture of gas for heating purposes. November 11.

18,175. A. J. Boulton.—From H. K. Flagler, United States. Improvements in solutions for facilitating the combustion of fuel. November 11.

18,176. A. J. Boulton.—From H. K. Flagler, United States. Improvements in apparatus for burning liquid fuel. November 11.

18,230. L. Van Vestrant and M. Graham. Improvements in the construction of shoots for charging inclined gas retorts. November 12.

18,360. H. Guyon and L. Métai. Improvements in the manufacture of combustible gas for heating, lighting, and generating of motive power. November 14.

18,419. G. B. Falconer. Improvements in or relating to apparatus for charging inclined gas retorts. November 15.

18,457. M. M. Brophy. Improvements in the utilisation of gas for heating purposes, and in apparatus therefor. November 15.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

18,163. F. Pritchard. Enriching and increasing the volume of gas from coal, and utilising the waste heat of retort settings. November 12.

19,721. F. J. Jones. Process and apparatus for the manufacture of illuminating gas. November 5.

19,763. F. Morris. Apparatus for charging inclined gas retorts. October 29.

20,551. J. West. Machines for charging gas retorts. November 5.

1890.

67. T. Parker. Distillation of coal, shale, &c., and production of a special coke. November 19.

343. W. T. Cotton and E. F. B. Crowther. Improvements in the manufacture of gas. November 19.

788. W. W. Horn.—From C. W. Jarrell. Apparatus for washing gas. November 19.

6553. A. Longsdon.—From F. Salomon. Obtaining oxygen gas from atmospheric air. November 12.

13,574. B. H. Thwaite. Method and apparatus for producing combustible gases. November 12.

15,012. W. B. McClure, E. Corning, T. Hodgson, J. E. McWilliams, and J. W. White. Artificial fuel, and manufacture of same. November 12.

#### III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

##### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

18,823. L. Zwillinger. Process and apparatus for production of charcoal, and recovery of acetic acid, wood-spirit, tar, ammonia, and gas. November 19.

1890.

67. T. Parker. See Class II.

1407. M. Lange. Separating the isomers contained in crude nitroalcohol. November 19.

#### IV.—COLOURING MATTERS AND DYES.

##### APPLICATIONS.

16,666. J. R. Geigy. Production of a yellow colouring matter or dye. October 20.

16,868. J. Y. Johnson.—From The Badische Anilin and Soda Fabrik, Germany. The manufacture and production of a new blue basic dyestuff. October 22.

17,168. J. Y. Johnson.—From The Badische Anilin and Soda Fabrik, Germany. The manufacture of sulpho acids of a red basic naphthalene colouring matter. October 27.

17,195. D. Dawson. Improvements in the production of blue colouring matters. October 28.

17,218. J. Zeller. See Class I.

17,538. C. A. Collin. Improvements in obtaining colouring matters. November 1.

17,712. B. Willecox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture and production of new derivatives of alizarine and its analogues. November 4.

18,024. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning, Germany. Production of a novel pynazon. November 8.

18,025. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning, Germany. Production of sodium formylphenylhydrazine and of symmetric alkylphenylhydrazine. November 8.

##### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

14,304. A. G. Green and T. A. Lawson. New azo-colouring matters. November 19.

1890.

39. R. J. Friswell. Manufacture of raw materials for dyestuffs. November 5.

134. R. J. Friswell and A. G. Green. Production of azo-colouring matters. November 12.

735. A. Bang.—From Dahl and Co. Production of dioxynaphthalene-monosulpho acid, and of diazo-dyestuffs therefrom. November 19.

1688. T. R. Shillito.—From J. R. Geigy and Co. Producing brown dyes. November 19.

1771. T. R. Shillito.—From J. R. Geigy and Co. Producing a yellow dye. November 19.

14,432. J. Dawson and R. Hirsch. Production of a substantive cotton colour. November 19.

#### V.—TEXTILES, COTTON, WOOL, SILK, Etc.

##### APPLICATIONS.

16,660. J. Menzies and G. Mitchell. A new process for treating textile fabrics and certain manufactured articles, so as to render them sun and heat proof. October 20.

16,985. D. Barnett. Improvements in the treatment of textile vegetable substances to obtain fibres therefrom, and in apparatus therefor. October 24.

17,342. B. Tettweiler. Improvements in and relating to fabrics composed mainly of fibrous material. October 30.

17,469. A. Grupe. A new or improved product suitable for the manufacture of floor cloth and imitation leather goods, and process of preparing the same, partly applicable to the manufacture of linoleum. October 31.

17,531. R. W. Thom. Improvements in backing or back stretching and finishing textile fabrics. November 1.

18,018. A. J. Boulton.—From G. Rudel, Germany. Improvements in the treatment of vegetable materials to convert them into textile fibres. Complete Specification. November 8.

18,119. C. Brodbeck. Improvements in the method or process for silkyfying, or rendering silky tissue threads or textile fibres by utilising every description of waste silk. Complete Specification. November 11.

18,284. P. W. Nicolle and J. Smith. Improvements in the treatment of vegetable fibrous matters to obtain fibres therefrom. November 13.

18,375. C. Campbell and H. D. Shaw. Improvements in scouring or treating wool and other fibrous materials or fabrics, and in means or apparatus employed therein. November 14.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1890.

200. J. Walker and W. Brown. Apparatus for drying or carbonising fibrous substances. November 12.

725. G. Broadbridge.—Partly from M. J. de Sant Anna. An improved fibrous material, and manufacture of same. November 5.

5482. G. W. Arnott, P. A. Olivier, and G. Seagrave. Washing and scouring wool and fibrous materials containing grease. November 19.

15,170. G. Schuler. Manufacture of linoleum, linerusta, eere-cloth, &c. November 19.

### VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

#### APPLICATIONS.

16,751. W. Laidlaw. Improvements in the method of and apparatus for dyeing yarns, tops, and the like. October 21.

17,074. W. H. Clegg and G. Kirby. Improvements relating to the production of wall papers and the like. October 25.

17,326. C. D. Abel.—From M. M. Rotten, Germany. Processes for dyeing textile materials of all kinds in the hyposulphite vat. October 29.

17,642. G. P. Gardner. An improved composition for fixing or mordanting colours, or for padding paper or other like material. November 4.

17,694. E. W. Foxlee. Printing with primuline. November 4.

17,769. T. F. Naylor and A. Naylor. Improvements in the construction of dye vats. November 5.

17,872. T. Salzmann. Improved process for the production of dyed cotton yarns or threads. Complete Specification. November 6.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1890.

2195. I. Braithwaite. Dyeing with indigo. November 12.

13,184. I. F. Peck. Apparatus for dyeing yarn. November 5.

14,897.—W. P. Thompson.—From F. Kornfeld. Dyeing, bleaching, and treating cops of yarn, &c., and apparatus therefor. October 29.

### VII.—ACIDS, ALKALIS, AND SALTS.

#### APPLICATIONS.

16,676. F. Ellershausen. Improvements in the treatment of soda waste. October 20.

16,842. C. Hope. Improvements in the manufacture of sulphuric acid. October 22.

17,150. W. P. Thompson. Improvements in or relating to the manufacture of bicarbonate of soda. October 27.

17,341. W. P. Thompson. Improvements in or relating to the manufacture of bicarbonate of soda. October 30.

17,392. M. Blumrich. Improvements relating to the manufacture of hydrofluosilicic acid and fluoride of silicon. October 30.

17,765. J. Simpson. Improvements in the employment of sulphuretted hydrogen in the manufacture of alkali and certain by-products. November 5.

17,836. S. A. Sadler. Improvements in the process employed in the manufacture of sodium bichromates. November 6.

17,855. W. Blagg. See Class I.

18,152. M. Goldschmidt. Method for producing alkaline nitrites. November 11.

18,187. L. D. Armstrong. Improvements in apparatus for recovering soda. Complete Specification. November 11.

18,240. F. M. Lyte. Improvements in the production of chlorine, and in the manufacture of soft burnt magnesia. November 12.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1890.

858. C. Roth. Manufacture of ammonium nitrate and sulphate, or chloride of sodium and of potassium. November 12.

9793. F. W. A. Frerichs. Manufacture of carbonates of alkalis and acetone. October 29.

14,022. C. Négrier. Furnaces for concentrating sulphuric acid. November 5.

15,544. H. J. Allison.—From M. M. Monsanto. Purifying brines. November 12.

### VIII.—GLASS, POTTERY, AND EARTHENWARE.

#### APPLICATIONS.

16,629. G. L. Schultz. See Class X.

16,901. W. Woodall. An improved combination of electro-coated and enamelled-coated surfaces for salts, dishes, and other similar articles. October 23.

17,968. J. P. Guy. Improvements in machines for pressing and making hollow earthenware articles. October 25.

17,117. D. Rylands. Improved means of manufacturing glass vessels and adapting the same for the storage and conveyance of compressed gases, and for similar purposes. October 27.

17,204. W. W. Pilkington. Improvements in kilns or tunnels for annealing plate glass, and in appliance used in connexion therewith. October 28.

17,255. H. Baggaley. Improvements in the manufacture of tiles and other porcelain, earthenware, and similar goods. October 28.

17,407. T. G. Webb. Improvements in the manufacture of glass retorts as used in chemical works for the concentration of acids, and other analogous purposes. October 31.

17,489. W. T. Croke. An improvement in the manufacture of "black pottery." November 1.

17,505. E. Cable. Improvements in and relating to the decoration of glass. November 1.

17,573. J. Dunnachie. Improvements in kilns for firing firebricks, earthenware, and the like. Complete Specification. November 3.

17,952. A. J. Boulton.—From H. Thumler, Germany. Improvements in the manufacture of glass chains. Complete Specification. November 7.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

17,468. D. Rylands. Manufacturing hollow glass-ware and tubes by machinery. October 29.

19,734. D. Rylands. Manufacture of glass tubes, sheets, and ware. November 5.

20,234. J. J. Candlish and W. Hall. Manufacture of hollow glass-ware, and apparatus therefor. November 12.

20,619. J. G. Sowerby. Cutting glass cylinders, &c. November 5.

1890.

738. C. F. Bailey. Method for supporting pottery-ware whilst being fired. November 12.

8917. C. T. Maling. Manufacture of china or earthenware vessels. November 19.

12,794. G. A. Marsden. Decoration of ceramic ware. November 19.

14,628. J. Sherwin. Devices for supporting earthenware while being fired. November 5.

## IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

### APPLICATIONS.

16,648. H. J. Allison.—From A. Manara and A. Guglielmina, Italy. Improvements in paving stones. October 20.

16,737. J. A. Archer. An improved material for covering roofs, and manufacturing the same. October 21.

16,777. P. C. Biron and C. Roswag. Improvements in the manufacture and production of refractory materials. October 21.

16,789. R. Stobe. Improvements in the manufacture of fireproof plastic material for cement, also applicable to smelting and various other useful purposes. October 21.

17,153. M. Hirsch and H. Reinisch. Improvements in macadam pavement. October 27.

17,795. F. Oschwald. New or improved building material. Complete Specification. Filed November 5. Date applied for July 5, 1890, being date of application in Belgium.

18,459. C. S. Haessler. Improvements in fire and weather-proof roofing. Complete Specification. November 15.

18,468. F. Jurschina and R. Ritter von Gunesch. A new or improved manufacture of artificial stone or composition, and building blocks and other articles thereof. November 15.

### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

19,092. W. S. Akerman. Boilers for utilising the waste heat of cement, &c. kilns. November 5.

1890.

13,384. J. Jungbluth. Composition or concrete flooring. October 29.

15,678. W. A. Robinson and J. Y. Terry. Plastering compositions. November 12.

15,784. G. A. Wright. Brick, block, tile, or slab for building purposes. November 12.

15,900. L. Sterne. Manufacture of cellular non-conducting blocks. November 12.

16,231. P. Crean. Method of, and kiln for, burning bricks. November 19.

## X.—METALLURGY, MINING, Etc.

### APPLICATIONS.

16,629. G. L. Schultz. Extraction of iron from minerals used in manufacture of glass, china, earthenware, and similar goods. October 20.

16,685. P. G. Biron. Improvements in treating cupreous materials, and obtaining copper and other useful products therefrom. October 20.

16,694. J. Harris. Improvements in machinery or apparatus to be used for the extraction of gold and silver from their ores by the amalgamation process. October 20.

16,724. J. B. Renshaw. An improvement in the manufacture of cast iron. Complete Specification. October 21.

16,802. E. Herz. Improvements in cupola and such like furnaces. Complete Specification. October 21.

16,887. T. S. Lindsay. Improvements in the preparation of aluminium fluoride and double fluorides, and in the manufacture of aluminium from fluorides. October 23.

17,036. J. C. Mitchell. An improved method of extracting metals from their ores, and appliances connected therewith. October 25.

17,953. W. Truran. Improvements in machinery or apparatus for cooling and discharging slag. October 25.

17,981. J. Harper and Co., Lim., and H. Devonport. Improvements in annealing furnaces. October 25.

17,165. H. Lobausen. A process for producing copper blocks with steel core for the manufacture of telegraph and telephone wire. October 27.

17,173. J. C. Bull. Improvements in refining copper. October 27.

17,186. S. B. Evans. A gas ingot-heating furnace, with improvements for iron or steel works. October 28.

17,191. F. H. Varley. Improvements in smelting furnaces. October 28.

17,279. The Manchester Oxygen (Brin's Patent) Co., Lim., and B. H. Thwaite. Improvements in the manufacture of steel and iron, and in apparatus therefor. October 29.

17,380. J. von Langer and L. Cooper. Improvements in or connected with reverberatory furnaces for puddling or smelting iron, and for other purposes. October 30.

17,613. P. M. Justice.—From J. Meyer, Germany. Improvements in the manufacture of steel and ingot iron. Complete Specification. November 3.

17,621. H. Grafton. An improved process of case-hardening or steelifying. November 3.

17,623. J. Garnier. Process for the manufacture of metallic nickel, together with alloys of nickel and iron, utilisable either direct or for the manufacture of nickel steel or nickel and carbonised iron castings. November 3.

17,625. B. Richards. Improvements in furnaces for smelting copper and other ores. November 3.

17,663. E. P. Martin and E. James. An improved method of and means for preparing moulds for casting pig iron, and for breaking the pigs and separating them from the "sow." November 4.

17,935. N. Lébédoff. Improvements in and means or apparatus for the extraction of metals from metallic ores or matters containing metals. November 7.

18,066. Davies Bros. and Co., Lim., and M. Bayliss. Improvements in and connected with the galvanising of sheet metal. November 10.

18,080. C. Hopfner. An improved method of treating cupreous liquors for the purpose of utilising the same. November 10.

18,171. W. P. Thompson.—From M. F. Coomes and A. W. Hyde, United States. Improvements in or appertaining to the manufacture and tempering of steel. Complete Specification. November 11.

18,235. W. D. Bohm. Improvements in the separation of gold and silver from ores or materials containing them. November 12.

18,276. J. Riley. Improvements in and connected with ingot moulds, such as are used in the manufacture of steel. November 13.

### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

19,148. J. C. Bull. Manufacture of metallic alloys and compounds. November 5.

19,632. T. H. Johns. Manufacture of tin andterne plates, and apparatus therefor. October 29.

19,653. T. H. Johns. Means and apparatus for coating and finishing sheet iron. November 12.

1890.

877. D. Elliott. Furnaces for heating iron or steel. November 19.

13,259. C. T. J. Vautin. Apparatus for extraction of gold. November 5.

14,837. C. E. Bernard. Production of dissolving and reducing agent, and employing same for coating metals with metals or combinations with metalloids, extracting metals from ores or combinations, or in arts in which dissolving or reducing action is required. November 5.

14,846. W. H. Kennedy. Method and apparatus for producing mineral wool. November 5.

15,833. E. Tweedy. A tempering fluid for treating steel. November 19.

15,859. J. L. Hopper. Process and composition for softening and subduing refractory ores. November 19.

## XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

### APPLICATIONS.

16,747. J. R. Thame. Improvements in the manufacture of electrical insulating materials. October 21.

16,837. J. E. Douglass. Improvements in the manufacture, construction, and building up of secondary battery elements, electrodes, or plates. October 22.

16,844. H. Weymersch. An improvement in the construction of accumulators or secondary batteries. October 22.

16,934. M. Azapis. A new electric battery. October 23.

17,277. R. Wotherspoon.—From H. Rowley, Australia. An improved method of and apparatus for the electrical treatment of sewage, wines, oils, air, gases, and other fluids. October 29.

17,444. M. Muthel. An improved filling for galvanic batteries. October 31.

17,954. H. L. Maugras. Improvements in electrical accumulators or storage batteries. November 7.

18,096. V. Baron von Alten. Improvements in galvanic elements. November 10.

18,180. Sir C. S. Forbes, Bart. Improvements in primary batteries, and in apparatus connected therewith. November 11.

18,248. J. A. Mays. Improvements in electrolysis. November 12.

18,339. W. R. Lake.—From A. Dehuard, France. An improved process and apparatus for the production of oxygen and hydrogen by electrolysis. November 14.

### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

20,856. D. G. FitzGerald and A. H. Hough. Elements for voltaic batteries. October 29.

1890.

232. J. Hopkinson, E. Hopkinson, and G. A. Grindle. Electric motors and dynamo-electric machines. October 29.

761. O. Dahl. Generating electricity by gas batteries. November 12.

6032. M. W. Dewey. Electric heating apparatus. October 29.

8242. W. R. Lake.—From H. Lemp. Electric welding apparatus. October 29.

12,830. H. H. Lake.—From G. A. Johnson and S. L. Holdrege. Secondary batteries and electrodes therefor. October 29.

13,421. W. P. Thompson.—From C. L. Coffin. Method and apparatus for working metals electrically. October 29.

15,456. W. P. Thompson.—From C. L. Coffin. Welding metals electrically. November 5.

15,482. H. H. Lake.—From The Crosby Electric Co. Electric batteries. November 5.

16,322. S. C. C. Currie. Insulating cells for electric batteries. November 19.

16,415. M. W. Dewey. Method and apparatus for utilising electricity in the formation of sheet metal articles. November 19.

## XII.—FATS, OILS, AND SOAP MANUFACTURE.

### APPLICATIONS.

17,160. E. Hermite, E. J. Paterson, and C. F. Cooper. A process for bleaching palm oil and other vegetable oils. October 27.

17,275. C. R. Illingworth. Improvements in soaps for diseases of the skin. October 29.

17,624. C. Moritt. Improvements in the treatment of linseed oil. November 3.

17,792. E. L. Downing and S. Hern. Improvements in cleansing or washing compositions. November 5.

18,031. A. Gutensohn. An improved compound for use in lieu of palm oil. November 8.

### COMPLETE SPECIFICATIONS ACCEPTED.

1890.

4137. F. Piekenbroek. Producing ozonised oils. November 12.

13,803. C. A. Jensen.—From P. Möller. Manufacture of cod-liver oil. November 12.

## XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

### APPLICATIONS.

16,654. S. Banner. Improvements in compositions applicable in the manufacture of oilcloth, varnish, pigment, menstrua, cement, binding material for so-called asphalt for giving body to oil, and for other like purposes, and method of manufacturing the same. October 20.

16,757. T. W. Just, R. Weiler, and O. Heidepriem. An improved ink. Complete Specification. October 21.

16,786. W. A. Hall. Improvements in the manufacture of paints. Complete Specification. October 21.

16,916. T. Drake. A new turpentine, and means of producing same. October 23.

17,197. C. A. Fawsitt. Improvements in compounds to be used in vulcanising rubber and other substances or compounds. October 28.

17,313. A. O. Watkins. Improvements in the production of uranium yellow, or compound oxides of uranium. October 29.

17,346. J. Haake. Improvements in the preparation of colours for distempering. Complete Specification. October 30.

17,446. R. Wood. Improvements in means or apparatus for filtering, more especially applicable in the manufacture of varnish and japan. October 31.

17,597. G. Chapman. Improvements in the method of manufacturing white lead. November 3.

17,839. J. MacHale. Anti-fouling paint. November 6.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

20,830. C. Huelser.—From G. Callmann. Process and composition for producing printing ink. November 12.

1890.

16,017. W. Dyshko. Transferred to Class XIV.

## XIV.—TANNING, LEATHER, GLUE, AND SIZE.

## APPLICATIONS.

16,793. J. Patterson. Improvements in fertilising compounds or fertilisers. Complete Specification. October 21.

17,853. T. O. Butler. An improved glue compound. Complete Specification. November 6.

18,385. L. A. Groth. Improved process and apparatus for tanning hides and skins. November 14.

## COMPLETE SPECIFICATION ACCEPTED.

1890.

16,017. W. Dyshko. Preparing and waterproofing skins. November 19.

## XV.—AGRICULTURE AND MANURES.

## COMPLETE SPECIFICATION ACCEPTED.

1890.

5419. J. Guillaume. Treatment of organic matters for production of manure, and apparatus therefor. October 29.

## XVI.—SUGARS, STARCHES, GUMS, Etc.

## APPLICATIONS.

17,232. H. H. Leigh.—From F. T. Romiguières, France. Improvements in refining sugar. October 28.

17,557. A. Wohl and A. Kollrepp. Improvements in the production of invert sugar. November 1.

## XVII.—BREWING, WINES, SPIRITS, Etc.

## APPLICATIONS.

16,746. E. D. Alexander. Moss beer, the ideal drink for invalids, dyspeptics, and ladies nursing. October 21.

16,942. F. T. Simson and J. Cox. Kola or caffenin, or theine malt liquors, fermented wines, and spirits. October 23.

16,951. H. Bates, jun. Improvements in corn product for brewers' use, and in the manufacture thereof. Complete Specification. October 23.

17,329. J. Rose. Brewing oatmeal stout and porter. October 29.

17,640. R. H. Leaker and J. H. Howell. Improvements relating to brewers' and distillers' fermenting vessels and yeast receivers. November 4.

18,099. T. P. Hinde. The boiling of malt and other liquors by coal and coke fire, gas, or other refined heat most applicable. November 10.

18,123. A. G. Hopkins. Charging fermented liquids in cask with carbonic acid gas, and for introducing carbonic acid gas into casks on draught, in lieu of atmospheric air. November 11.

18,212. E. J. Mills and R. Barr. Improvements in the treatment of alcoholic liquids. Complete Specification. November 12.

18,340. F. S. Willoughby and A. Mudie. Improved method of maturing spirits. November 14.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

20,434. B. Hoff and J. Frommel. Apparatus for rectifying spirits, &c. October 29.

20,630. L. Haas. Apparatus for collecting for use the excess of carbonic acid generated during brewing. November 12.

1890.

667. W. P. Thompson.—From J. A. H. Hasbrouck. Process and apparatus for ageing liquors. November 19.

678. E. Edwards.—From F. Hofmeister. Method and apparatus for obtaining accelerated fermentation and producing sparkling drinks. October 29.

3606. E. Carez and La Société Générale de Maltose. Saccharification of amylaceous substances. November 19.

## XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

## APPLICATIONS.

*A.—Chemistry of Foods.*

16,713. S. J. P. Pellatt. Improvements in the method of treating and preparing hops, and blending the same for infusion together with tea, coffee, cocoa, and other substances for which such prepared hops are applicable. October 21.

16,828. T. Eleoate. An improved method of preserving uncooked meats. October 22.

16,857. M. A. E. Schneider and R. H. Coall. The treatment of a certain fruit in order to convert it, either alone or combined with other substances, into food and drink for infants, invalids, and others. October 22.

17,104. L. Bremond. Electrically destroying insects and parasites, and preserving animal and vegetable foods and drinks. October 25.

17,245. B. Wilcox.—From The Rumford Chemical Works, United States. Improvements in baking powders and like preparations. Complete Specification. October 28.

17,427. B. G. Hadnut. New or improved corn products, and process for manufacturing the same. Complete Specification. Filed October 31. Date applied for April 5, 1890, being date of application in United States.

18,368. W. Paterson. The manufacture of a new or improved sweet or sweet food, or preserve. November 14.

*B.—Sanitary Chemistry.*

16,728. G. E. Davis and A. R. Davis. The treatment of sewage, and utilisation of the by-products. October 21.

16,836. J. Lowe. Precipitating and filtering sewage. October 22.

16,972. F. P. Candy. Improvements in and in the preparation of material for use in the treatment of sewage and other polluted water and liquids. Complete Specification. October 24.

17,113. W. Birch. See Class I.

17,453. J. W. Slater and The Native Guano Co., Lim. Improvements in the preparation of agents for use in the purification of sewage and other polluted water by precipitation, and improvements in the treatment of sewage and other polluted water, in order to effect the purification thereof. October 31.

17,686. E. W. Cracknell. An improved furnace for the incineration and destruction of house garbage, town refuse, and such like noxious matters. Complete Specification. November 4.

17,687. E. W. Cracknell. Improvements in the treatment of night soil and such like noxious matters, and in apparatus therefor. Complete Specification. November 4.

*C.—Disinfectants.*

17,943. J. A. Phillips. Improvements in disinfectants and deodorisers. November 7.

## COMPLETE SPECIFICATIONS ACCEPTED.

*A.—Chemistry of Foods.*

1889.

19,281. E. Edwards.—From A. Seidensticker. Method and apparatus for preserving milk. November 12.

1890.

14,888. G. F. Meyer. Method and apparatus for extracting salt from victuals by osmose. November 12.

*B.—Sanitary Chemistry.*

1889.

18,291. Destructors for combustion of refuse, and disposing of or utilising the products of combustion therefrom. November 12.

1890.

472. C. Jones. Destructors for treating refuse. November 19.

480. E. Devonshire. Purifying water, and apparatus therefor. November 19.

5419. J. Guillaume. See Class XV.

7840. W. C. Young. Purification of water by distillation. November 12.

*C.—Disinfectants.*

1889.

18,512. J. Price. Disinfectants and deodorisers. October 29.

20,231. A. Artmann and H. W. Kufcke. Producing disinfectants. November 5.

## XIX.—PAPER, PASTEBOARD, Etc.

## APPLICATIONS.

16,910. C. R. F. Schloesser and J. M. Campbell. Improvements in the manufacture of paper and in apparatus therefor. October 23.

16,928. H. B. Watson and J. S. Watson. Improvements in the manufacture of strainer or knotted plates for straining paper pulp, wood pulp, and the like. October 23.

17,012. G. L. Anders and C. H. Elliott. Improvements in the use and application of xylonite, celluloid, and the like. Complete Specification. October 24.

17,268. A. Wilbaux. Improvements in or relating to the treatment of vegetable parchment and the like. Complete Specification. October 28.

18,169. W. P. Thompson.—From P. R. Thom, United States. Improvements in apparatus for straining or screening paper pulp. November 11.

18,215. R. E. Fraser. The improvement of paper for the use of water-colour artists and others. November 12.

## COMPLETE SPECIFICATIONS ACCEPTED.

1890.

795. R. Stone. Treatment and utilisation of peat, sawdust, and other fibrous and vegetable materials. November 12.

15,995. F. V. L. Hiorth. Apparatus for boiling wood pulp. November 12.

## XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

## APPLICATIONS.

17,221. C. Kolbe. Improvements in the manufacture or production of salols. October 28.

17,547. G. de Laire. A manufacture of iso-engenol and of certain of its derivatives and their application to the manufacture of vanilline. November 1.

18,021. B. Willeox.—From The Farbenfabriken vormals F. Bayer and Co. Improvements in the manufacture of periodides of isobutyl phenols, and of isobutyl cresols. November 8.

18,022. B. Willeox.—From The Farbenfabriken vormals F. Bayer and Co. Improvements in the manufacture of methyl- and ethyl-phenacetin. November 8.

18,246. O. Imray.—From The Amsterdamsche Chinine-fabrik, Holland. Process for the production of anthranilic acid. November 12.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

20,392. J. A. Kendall. Manufacture of hypophosphites. November 5.

1890.

5940. H. H. Lake.—From La Société Anonyme des Parfums Naturels de Cannes. Method and apparatus for extracting and purifying perfumes, oils, &c. November 12.

## XXI.—PHOTOGRAPHIC PROCESSES AND MATERIALS.

## APPLICATIONS.

17,189. J. E. Thornton. Improvements in connection with flexible films for photographic and other purposes, and in the manufacture, and in apparatus used in the manufacture of the same. October 28.

17,339. R. Fowler. Improvements in and appertaining to cameras and sensitive plates for photographic purposes. October 30.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

17,773. E. H. Farmer. Improvements in photography. October 29.

1890.

401. T. H. Redwood. Means or apparatus for producing flash light for photography. November 12.

## XXII.—EXPLOSIVES, MATCHES, Etc.

## APPLICATION.

18,472. G. Trench. Improvements in explosives. Nov. 15.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

17,430. A. Walter. Percussion and time fuses. Nov. 5.

18,738. A. Martin. Percussion fuses. November 19.

19,935. A. T. Cocking. Treating and using explosives so as to control and quench the flame. November 12.

19,971. A. Martin. Percussion fuses. November 19.

20,104. The Roburite Explosives Co., Lim., C. Roth, and W. J. Orsman. Treatment or preparation of nitrate of ammonium. November 12.

## NOTICES.

Members are hereby advised that the subscription of 25s. for 1891, payable on January 1st next, should be sent in good time to the Treasurer in order to ensure continuity in the receipt of the Society's Journal. Any changes of address which it is desired should appear in the new List of Members should reach the General Secretary not later than January 15th, 1891.

Post Office Orders should be made payable at the General Post Office, London, to the Honorary Treasurer, E. Rider Cook, and should be forwarded to him at Bow, unless it be desired to notify a change of address.

Members who require extra sets or back numbers of the Journal are requested to make application to the General Secretary only, to whom also changes of address should be communicated.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 41 of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed.

The Secretary is instructed to negotiate for the purchase of copies of the Society's Journal for January and May 1883, and January, February, and April 1886. Members possessing odd copies of these numbers are particularly requested to communicate at once, stating price required, with Mr. Cresswell. The stock of all other numbers is at present sufficient for the Council's requirements.

#### LIST OF MEMBERS ELECTED, 23rd DECEMBER, 1890.

Campbell, Colin M., c/o Sadler and Co., Chemical Works, Middlesbrough, organic chemist.

Collins, S. Home, 13, Kyverdale Road, Stoke Newington, N., analytical chemist.

Crawshaw, E., 25, Tollington Park, N., aniline dye merchant.

Dore, Jas., Copper Works, High Street, Bromley-by-Bow, E., distillers' engineer.

Forrester, Albert, Arcot, Madras, India, chemist and distiller.

Green, Alfred H., Oaklands, Lowton St. Mary's, near Newton-le-Willows, Lancashire, manufacturing chemist.

Hargreaves, Mark, 108, Fylde Road, Preston, chemist.

Laidler, T. S., Newcastle Chemical Works, Gateshead, analytical chemist.

Ling, Arthur R., 53, Sugden Road, Wandsworth, S.W., sugar chemist.

Moore, Thos., "Le Nickel," Oroné, Thio, New Caledonia, analytical chemist.

Smaill, Wm., P.O. Box 1554, Montreal, Canada, analytical chemist.

Smith, R. Greig, Springwells, New Street, Musselburgh, N.B., chemist.

Smith, Robt, Watson, Young's Oil Co., Lim., Uphall Station, N.B., chemist.

Stewart, Robt., c/o Boake, Roberts, and Co., Warton Road, Stratford, E., chemical works manager.

Werner, Emil A., 5, Church Avenue, Rathmines, Dublin, chemical lecturer.

Boyd, Wm., 1/o Glasgow; Thornton, R.S.O., Fifeshire, N.B.

Bradbury, A., 1/o Mason Buildings; Queen Buildings, 11, Dale Street, Liverpool.

Caines, C. M., 1/o 5; 7, Rochester Terrace, Camden Road, N.W.

Crichton, Donald, Journals to P.O. Box 789, G.P.O., Sydney, New South Wales.

Crossley, L., 1/o Pelham Grove; 28, Parkfield Road, Sefton Park, Liverpool.

Cunningham, A. A., 1/o American Sugar Refinery; Chemical Laboratory, 14, Chronicle Buildings, San Francisco, Cal., U.S.A.

Fielding, A., 1/o Dantzic Street; George Street, Salford, Manchester.

Findlay, J. T. J., Journals to c/o Messrs. Chapman and Messel, Silvertown, E.

Gray, G. Watson, 1/o 12; 14, Argyle Road, Garston.

Harvey, E. W., 1/o Clapham Common; Hilsrig, Alderbrook Road, Balham, S.W.

Hay, Alex., 1/o Lincoln; Heath Villa, Shaftesbury Avenue, Bristol.

Hedley, Jno., jun., 1/o Fenchurch Street; 11, Crooked Lane, Cannon Street, London, E.C.

Kitamura, Y., 1/o Berlin; 72, Camden Road, London, N.W.

Kleeman, Dr. S., 1/o Manchester; 52, Mill Lane, Old Swan, Liverpool.

Lagerwall, Dr. Ivar, 1/o Brussels; c/o Nobel Bros., St. Petersburg.

Orr, Alex., 1/o Sydney; 1, Park Terrace, Irvine, N.B.

Pugh, Geo., 1/o Mark Lane; 71, Milson Road, West Kensington Park, W.

Reid, W. G., Journals to c/o Reid and Mackay, Old De Beers, Kimberley, South Africa.

Roberts, F. G. Adair, 1/o Bethune Road; Lion House, Amburst Park, Stamford Hill, N.

Stahl, Dr. Karl F., 1/o Johnstown; 57th Street and A.V.R.R., Pittsburgh, Pa., U.S.A.

Thomson, J. S., Journals to Uphall Oilworks, Uphall Station, N.B.

Tyrer, Thos., 1/o Battersea; Stirling Chemical Works, Abbey Lane, Stratford, E.

Warne, Thos., 1/o Wallsend; 118, Wednesbury Road, Walsall.

Wood, E. T., 1/o Malvern; Brinseall, Chorley, Lancashire.

Wright, Alf., 1/o Newcastle; 12, Richmond Villas, Seven Sisters Road, Holloway, N.

Wuth, Dr. A., 1/o Dambachthal; 37, Kapellerstrasse, Wiesbaden, Germany.

#### Deaths.

W. Lant Carpenter, 36, Craven Park, Harlesden, N.W.

Charles Marvin, Grosvenor House, Plumstead Common, Kent.

#### CHANGES OF ADDRESS.

Beckett, G. H., Journals to 133, Bewsey Road, Warrington.

Bloxam, A. G., 1/o Cirencester; 16, Bolingbroke Road, West Kensington, W.

## London Section.

#### SESSION 1890—91.

1891.

Jan. 5th.—Mr. Percy C. Gilchrist. "The Basic Copper Process."

Feb. 2nd.—Mr. W. C. Young. "On Standard Sperm Candles."

Feb. 16th:—

Mr. W. Macken. "Incandescent Gas Lighting."

Messrs. Cross and Bevan. "The Volumetric Estimation of Alumina."

March 2nd.—Mr. V. H. Veley. "The Chemical Changes between Nitric Acid and Metals."

March 16th:—

Mr. W. Crowder. "Observations made in the Working of Vitrified Chambers."

Mr. A. H. Allen. "The Chemistry of Whisky and Allied Products."

April 6th.—Professor Vivian B. Lewes:—

1. "The Analysis of Illuminating Gases."

2. "The Products of Checked Combustion."

April 20th.—Mr. W. P. Rix. "Stoneware: and its Application to Chemical Apparatus."

May 4th.—Professor Dewar, F.R.S., and Mr. Boverton Redwood, F.R.S.E. "A Process for the Conversion of Heavy Mineral Oils into Lighter Hydrocarbons suitable for Illuminating and other purposes."

June 1st.—Dr. W. S. Squire. "The Artificial Production of Cold theoretically and practically explained."

Meeting held Monday, December 1st, 1890.

MR. THOS. TYRER IN THE CHAIR.

### PURIFICATION OF SEWAGE AND CONTAMINATED WATER.

BY WM. WEBSTER.

THE term sewage many years ago was rightly applied to the excremental refuse of towns, but it is a most difficult matter to define the liquid that teems into our rivers under the name of sewage to-day; in most towns "chemical refuse" is the best name for the complex fluid running from the sewers.

It is now more than 10 years since I first commenced a series of experiments with a view of thoroughly testing various methods of purifying sewage and water contaminated with putrefying organic matter. It was while investigating the action of iron salts upon organic matter in solution and splitting up the chlorides present by means of electrolysis, that I first became aware of the importance of precipitating the soluble organic matter in such manner that no chemical solution should take the place of the precipitated organic matter. If chemical matter is substituted for the organic compounds, the cure is worse than the disease, as the resulting solution in most cases sets up after precipitation in the river into which it flows.

My first electrolytical experiments were conducted with non-oxidisable plates of platinum and carbon, but the cost of the first and the impossibility of obtaining carbon plates that would stand long-continued action of nascent chlorine and oxygen made it desirable that some modification should be tried. I next tried the effect of electrolytic action when iron salts were present, but did not think of using iron electrodes until after trying aluminium. I found that the action of non-oxidisable electrodes was most efficacious after the temperature of the fluid acted upon rose 4° or

5°; but the cost of working made it impossible on a large scale.

After a long series of experiments, iron plates were used as electrodes with remarkable results, for the compounds of iron formed not only deodorised the samples of sewage acted on, but produced complete precipitation of the matters in suspension, and also of the soluble organic matter; the resulting effluents remaining perfectly free from putrefaction. The first part of the process is well illustrated by the small experiments now shown; the organic matter in suspension and in solution separates into flocculent particles, which rise to the top of the liquid and remain until the bubbles of hydrogen which have carried them up escape, when the solid matter will precipitate. In the arrangement adopted on a working scale, the separated particles precipitate readily. As an illustration of the action upon organic matter in solution I take a small quantity of dye, mix it with water, and placing the connected iron electrodes in the mixture, the dye in solution separates into flocculent particles. The electrolytical action is of course easily understood, but the chemical changes that take place need an explanation. At the positive pole, hypochlorite of iron seems to be formed at first, but this is quickly changed into a protochloride, and as at the negative pole an alkaline reaction takes place, the iron salt is precipitated in the form of the ferrous hydrated oxide, together with the organic matters in suspension and solution. Owing to the carbonates that are always present in sewage, ferrous carbonate is also formed.

The success of these laboratory experiments led to a trial of the process on a larger scale, for hitherto only a gallon at any one time had been treated.

Small brick tanks were erected at my wharf at Peckham and iron electrodes fitted to them.

Wrought-iron plates were fixed about an inch apart, and connected in parallel in the tanks, forming one big cell. Sewage to the amount of about 200 gallons was run into the electrode tank and then treated, the results being so satisfactory that larger works were erected, when a supply of sewage equal to 20,000 gallons an hour could be obtained.

After a number of experiments had been carried out it was decided to run the sewage as rapidly as possible through electrodes, six cells or two rows in series fixed in a long channel or shoot, for experience showed that the motion of the liquid acted on reduced the back E.M.F. and hastened the formation of the precipitate.

A channel is kept at the bottom of the electrodes for the silt to collect, with a culvert at side to flush it into, so as to prevent any block occurring; the advantage of this is obvious. The plates in each section may be from half an inch to an inch thick, and can be of any length up to 6 ft. It may possibly be objected that a large number of plates is required. This may be so, but the larger the number of plates the less the engine power required, and the longer they last. In each section the electrodes are in parallel, and any one section is in series with the other, the arrangement being exactly alike that of a series of primary battery cells.

By actual experience I have been able to prove that at least 25 sections of electrodes should be in series, and across any one of these sections the potential difference need not be greater than 1·8 volts, the current being of any desired amount according to the surface of plates used.

The electrical measurements taken by Dr. John Hopkinson during these experiments for the Electrical Purification Association, to whom I had sold my patents, entirely corroborated my contentions as to E.H.P. used, and agreed with the measurements of the managing electrician, Mr. Octavius March.

The process was then thoroughly investigated by Sir Henry Rosevear, who had control of the works for one month. He reports as follows:—

"The reduction of organic matter in solution is the crucial test of the value of a purifying agent, for unless the organic matter is reduced the effluent will putrefy and rapidly become offensive.

"I have not observed in any of the unfiltered effluents from this process which I have examined any signs of putrefaction, but, on the contrary, a tendency to oxidise.

The absence of sulphuretted hydrogen in samples of unfiltered effluent, which have been kept for about six weeks in stoppered bottles is also a fact of importance. The settled sewage was not in this condition, as it rapidly underwent putrefaction, even in contact with air, in two or three days.

"The results of this chemical investigation show that the chief advantages of this system of purification are:

"First.—The active agent, hydrated ferrous oxide, is prepared within the sewage itself as a flocculent precipitate. (It is scarcely necessary to add that the inorganic salts in solution are not increased, as in the case where chemicals in solution are added to the sewage.) Not only does it act as a mechanical precipitant, but it possesses the property of combining chemically with some of the soluble organic matter and carrying it down in an insoluble form.

"Second.—Hydrated ferrous oxide is a deodoriser.

"Third.—By this process the soluble organic matter is reduced to a condition favourable to the further and complete purification by natural agencies.

"Fourth.—The effluent is not liable to secondary putrefaction."

Mr. Alfred E. Fletcher also investigated the process subsequently, and reports as follows:—

"The treatment causes a reduction in the oxidisable matter in the sewage, varying from 60 to 80 per cent. The practical result of the process is a very rapid and complete clarification of the sewage which enables the sludge to separate freely.

"It was noticed that while the raw sewage filters very slowly, so that 500 cc. required 96 hours to pass through a paper filter, the electrically treated sewage settled well and filtered rapidly.

"Samples of the raw sewage having but little smell when fresh, stank strongly on the third day. The treated samples, however, had no smell originally, and remain sweet, without putrefactive change.

"In producing this result two agencies are at work, there is the action of electrolysis and the formation of a hydrated oxide of iron. It is not possible, perhaps, to define the exact action, but as the formation of an iron oxide is part of it, it seemed desirable to ascertain whether the simple addition of a salt of iron with lime sufficient to neutralise the acid of the salt would produce results similar to those attained by Webster's process.

"In order to make these experiments, samples of fresh raw sewage were taken at Crossness at intervals of one hour during the day. As much as 10 grains of different salts of iron were added per gallon, plus 15.7 grains of lime in some cases, and 125 grains of lime in another, and the treated sewage was allowed to settle 24 hours; the results obtained were not nearly as good as by the electrical method."

During the present year a very searching investigation of the merits of various processes of sewage treatment has been made by the Corporation of Salford; amongst others of my electrical process. As the matter is at present under discussion by the Council, I am not in a position to give extracts from the reports of the engineers and chemists under whose supervision and control the work was done, but I may go so far as to say that the results of my system of electrical treatment have proved its efficiency and applicability to sewages of even such a foul nature as that of Salford and Pendleton. The system was controlled continuously for the Corporation by Mr. A. Jacob, B.A., C.E., the borough engineer; Mr. J. Carter Bell, F.I.C., &c., county analyst; Messrs. John Newton and Sons, engineers, Manchester; Mr. Giles, of Messrs. Mather and Platt, electrical engineers, Manchester; Dr. Charles A. Burghardt, Lecturer in Mineralogy at Owens College.

I would also refer you to a paper recently read before the Manchester Section of this Society by Mr. Carter Bell, the borough analyst for Salford, in whose remarks Dr. Burghardt, an independent authority, permits me to add that he concurs. He cannot give details until his report has gone in, which will be very shortly. (See p. 1101.)

Mr. Carter Bell's report has gone in, and although he is precluded also from giving full details, he has kindly put at

my disposal samples sealed by him of the effluents produced by the electrical treatment which I now submit, together with the analyses, as follows:—

	Parts in 100,000.			
	May 15.	June 7.	June 30.	July 25.
Total solids.....	Not filtered. 109	125	141	152
Loss on ignition .....	33	21	29	23
Chlorine.....	32	44	42	43
Oxygen required for 15 minutes .....	2.56	0.76	0.27	0.79
Oxygen required for three hours.....	4.27	0.79	0.50	1.00
Free ammonia .....	2.20	0.88	0.50	0.92
Albuminoid ammonia.....	0.32	0.17	0.092	0.19

The samples are taken at random.

Whether the process will or will not be adopted by the Salford authorities I am of course unable to say, but I think I may safely say that the electrical process has now absolutely proved its case in regard to the solution of the sewage problem. It is simple, efficient, and I am sure more economical than any other known process where duration is taken into account.

In regard to the Salford trials it may be interesting to give the following particulars:—

The electrical shoot was built in brick and contained 28 cells arranged in series.

Each cell contained 13 east-iron plates 4 in. × 2 ft. 8 in. ×  $\frac{1}{8}$  in. thick connected in parallel.

The available electrode surface in each cell was 256 sq. ft.

The ampère hour treatment required for Salford was found to be about 37 ampère hours per gallon, and the I.H.P. per million gallons based on these figures would be 37.

NOTE.—In estimating for the plant necessary for treating the whole of the Salford sewage, a margin was allowed on above figures. The A.H.T. was taken at 44 and the I.H.P. per million at 39 to 39.5.

Mr. Octavius March, electrical engineer, who has followed the process from the commencement, and who superintended the electrical details both at Crossness and Salford, will give you on the blackboard a rough sketch of the above trial plant.

The Salford tanks are admirably adapted to the application of the electrical, or in fact any process of precipitation. They are 12 in number, and it is proposed to take two end tanks for the electrical channels, in which the iron electrodes would be placed.

The total I.H.P. required for treating the whole of the Salford and Pendleton sewage, taken at 10,000,000 gallons per 24 hours, is calculated at 400 I.H.P., based on the actual work done during the trial. The electrical plant would consist of four engines and dynamos, any three of which could do the whole work, and three boilers, each of 200 I.H.P.

The total cost of plant, including alterations, is estimated at 16,000*l.*, to which must be added the cost of about 5,000 tons of iron plates—ordinary cast iron—at say, 4*l.* per ton. These plates would last for several years.

If filtration were required, there would be an extra expenditure for this, but it will be remarked that as the treated sewage is practically purified when it leaves the electrical channels, these filters would be only required for complete clarification, which for most places would not be a necessity.

The filtering material used could be gradually prepared from the sludge obtained after electrical treatment, unless it could be more profitably sold as a manure, and I am not a believer in the value of sewage sludge in large quantities. This sludge, a waste product, is converted into *magnetic oxide of iron*, of which I have here two small samples. This magnetic oxide is a good filtering material, but, like

every other filtering material, it would of course require renewal. There would, however, always be a supply of the waste product—sewage sludge—on the spot, and the spent magnetic oxide recarbonised could be used indefinitely.

The annual cost for dealing with the Salford sewage is estimated at in round figures 2,500*l.* for coal, labour, maintenance of engines, boilers, and dynamos. To this must be added the consumption of iron and its replacement, which would have to be written off capital expenditure.

If a colourless effluent were required, absolutely free from suspended matter, the additional cost is estimated at from 1,200*l.* to 1,500*l.*

#### DISCUSSION.

Dr. GUSTAV BISCHOF wished to emphasise the great difference with which the sewage question was approached 20 years ago as compared with the present time. Twenty years ago one used to hear of the *utilisation* of sewage; now the question had become the *disposal* of sewage. In other words, we were satisfied now if we could get rid of our sewage with a reasonable expenditure of money. With regard to the process so ably brought before the notice of the meeting, he was under the disadvantage of having no practical experience with it. He could only come forward as a theorist, referring to some researches, and leaving the meeting to judge of their bearing. Sewage was a very complicated body, containing matters in solution and in suspension, both organic and mineral. Amongst the matters in suspension were the living organisms, and if he had understood the paper correctly, the author attached great, perhaps the greatest, importance to these. The question thus arose, what became, from a biological point of view, of the sewage after it had passed Mr. Webster's sewage works? Was it still capable of causing nuisance? This question was essential in considering the effect of the process in purifying sewage. The first experiments on the action of electricity on microphytes were, he believed, made by Schiel in 1875. The criterion was then the suspension of motion, which was now known to be a mistake, since a great number of organisms were capable of resuming motion after its temporary absolute cessation. The next and only other experiments on the subject that he was aware of were made about 1883 by Drs. Ferdinand Cohn, of Breslau, and Mendelssohn. Their first attempts were with a "constant" Daniel's cell, which they soon found to be constant only in name, and discarded for the Marié-Davy cell. Though this was a strong cell, the first experiments with one cell only produced no perceptible effect. Then they had recourse to two cells; but although the result was an appreciable diminution of organisms, life was by no means finally extinguished. If some of the same nutritive medium—which was a purely mineral one—was sterilised and then inoculated with a drop of the liquid resulting from the experiment, the mixture soon became full of life. Only when using two strong Bunsen zinc carbon cells together with the two Marié-Davy's all life ceased, as inoculation with the liquid thus treated was ineffective. In all the experiments the electrical treatment was continued for 24 hours, and the temperature was maintained at 30° to 35° C. He would leave the members to draw their own conclusions from these facts whether any such conditions existed in Mr. Webster's process. He believed that Mr. Webster attached some importance to the elimination of chlorine?

Mr. WORTH dissented.

Dr. BISCHOF, continuing, said: As Mr. Webster did not attach importance to that point, he would not pursue it, but would conclude by wishing the author all success with his method, feeling sure that he fully recognised that criticism was the backbone of success.

Mr. W. C. SILLAR considered that the sewage problem, though not the greatest difficulty of the age, was nevertheless of such importance that one ought to hail with pleasure any genuine attempt to solve it. He would like to ask the author, firstly, whether the electrical process removed the dissolved as well as the suspended impurities of the sewage; secondly, whether the impurities so separated lay so exclu-

sively at the bottom of the tank that the effluent could be run off without fear of disturbing it or carrying some of it into the river. Thirdly, he would like to ask whether the electrical process was applied merely to the "disposal" of sewage, or whether it provided for that "utilisation" of it which, as the last speaker had said, was the idea 20 years ago. He was strongly impressed with the idea that every evil that came under his notice had in some way or other a duplicate: that if the evil took the form of matter out of place, there was a place for it void somewhere. The same matter which polluted our rivers, if properly utilised, would become the solution of our agricultural difficulties. No solution of the sewage difficulty could be considered satisfactory unless it provided for its appropriation in whole or in part to agricultural purposes. The precipitation process at Kingston did so provide, and he thought it would be possible to compare the two processes in very few words so as to ascertain whether the one now before them possessed any advantages. First of all, the effluent water from the A.B.C. process was sufficiently purified to satisfy the requirements of the authorities, and was not at all deleterious to fish life in the river. He presumed that Mr. Webster claimed this point, but it was quite certain that the electrical process could not be superior to the Kingston process in that respect. Secondly, the area required for the A.B.C. treatment was very small, and he supposed that Mr. Webster would also claim that. Thirdly, no subsequent filtration or irrigation was required. On that point he understood Mr. Webster to say that his effluent required subsequent filtration to render it clear. This would be found to be a great disadvantage in many localities, where it was essential that the sewage treatment should be begun and ended in the sewage works. Lastly, and most important of all, at Kingston the sludge was prepared and dried, and had both an agricultural and a market value, in proof of which he might state that upwards of 10,000 tons had been made and sold at 70*s.* a ton. Did Mr. Webster claim that his sludge had any agricultural or market value? Had he ever sold any of it? If not, he had only half solved the difficulty.

Mr. P. BIRCH would be glad to be informed as to the cost per head per annum of dealing with sewage completely under this system; precipitating, drying, pressing, and getting it into such form as to be carried away. All sewage processes consisted largely of precipitation. One method might be cheaper than another in that respect, but it might involve more expense for drying. For example, they had just heard of another process which depended upon precipitation, namely, the A.B.C. process. No doubt that process gave a clear, sweet effluent, but it differed from the method under notice in that whereas the electrical process involved the addition of a very small amount of chemicals, Mr. Sillar's process required a large amount. In days like the present, when it was difficult to get rid of the sludge, and when they had to dry it in a cleanly manner, the quantity of material to be dealt with was an important consideration. He would ask whether it was not a fact that Mr. Sillar had been 20 years getting rid of his manure. They knew that there was a large fortune at his back pushing the manure on the market, and he believed that a great amount of skill was employed; but, as far as he could make out, the sludge which was dried and sold at 70*s.* a ton was the material which they saw depositing in the phial before them, plus a quantity of material which was infinitely less valuable. Did Mr. Webster base any recommendation of his process on the fact that when dried he could get 70*s.* a ton for his sludge? If not, no sound agriculturist would continue to give 70*s.* a ton for such matter mixed with clay or charcoal, worth only a few shillings a ton. With regard to the process immediately before the meeting, he would ask Mr. Webster to take upon himself the task of putting before them a little more information as to the outside cost of ridding sewage of suspended matter, and drying it, and also, when necessary, of obtaining a greater degree of purity. If they could get some figures of that nature, say a statement in pence per head of population, it would greatly assist members in forming an opinion of the value of the process. He knew that Mr. Sillar was very keen upon the question of agricultural depression and the prevention of

waste, but for his part, he thought that a greater sin than wasting a thing was spending more than it was worth in attempting to use it.

Mr. C. F. CROSS said that, apart from the economic question, there were some points connected with what actually took place in the electrolysis which he would be glad to have further explained. So far as he had understood the reader, the only information given respecting the actual operation of the current was that a hypochlorite of iron was formed at the anode, and they were left to guess what took place at the cathode. He presumed that in this electrolysis the operators relied upon the chlorides present in the sewage. Chloride of sodium being electrolysed in solution, the effect of the acid would be to dissolve the iron in the form of ferrous chloride, which would afterwards meet the base separated at the cathode, and thus ferroso-ferric hydrate would be precipitated. This would remove the dissolved oxygen of the dilute sewage. The presence of ferric oxide had been alluded to as a product of the action, but nowhere was it stated how the ferric condition was arrived at. He failed to see where the oxygen could be obtained to raise the iron from the ferroso-ferric to the ferric state otherwise than from the atmosphere. Assuming that the water was electrolysed, hydrogen and oxygen would be formed, but the only effect would be to fix the latter on the iron plates and simply oxidise the electrodes *in situ*, without producing any effect on the sewage. Mr. Webster would, he thought, confer a benefit on the Society if he dissected some of the elements of the problem and told them what took place at the electrodes, and how the products acted on the dissolved organic matters of the sewage. The organic matter should be selected with a view to determine precisely what this action of the electrolysis effected. Sir Henry Roscoe did not appear to have examined the condition of the discharged effluent in regard to its condition of aëration, and that was a matter which he (Mr. Cross) regarded as being very important, for if a lot of liquid deprived of oxygen were run into a sluggish stream, the abstraction of oxygen from the stream itself was likely to affect fish life in it. Seeing that the general interest in the paper was economic rather than scientific, he would not take up further time with such points as he had already raised; but he thought that in a matter of this kind, where a process departed in an essential particular from general practice, they had a right to ask that the elements of the problem should be laid before them. He would limit himself therefore to inquiring how the iron was raised from the ferroso-ferric to the ferric state, and whether in fact that was not done at the expense of the due aëration of the effluent.

Mr. B. E. R. NEWLANDS considered the process before the meeting to be a practical suggestion for dealing with the great sewage difficulty. They had all heard of the electric method of purifying sugar; and he had expected to find Mr. Webster's process something of the same kind, and was agreeably surprised to find himself mistaken. At the same time, he did not think the idea was quite new. About 20 years ago Mr. C. H. GILL passed electric currents through sugar solutions to free them from salts and organic matters, and in 1880 Messrs. Hodge, Hodge, and Eastick took out a patent for decomposing organic and inorganic substances by electrolysis, for the purpose of destroying colouring matters and other impurities contained therein. That patent did not relate to the purification of sugar solutions only, but was very wide in its claims. The inventors used metal plates and passed currents through them so to make them alternately anodes and cathodes, the impurities being eliminated in the form of a slime.

Mr. ALFRED E. FLETCHER rose in obedience to the invitation of the Chairman, though he could add nothing material to his opinion quoted in the paper, and which had been given after careful investigation of the process. He might, however, remark in reply to Mr. Cross that the process did not produce ferric oxide. The oxygen in the sewage water had been taken up by the organic matter itself, and, as might be expected, a ferrous salt was produced. The after-oxidation, if any, was due to exposure to the

atmosphere. An effluent was produced which was bright in appearance, innocuous, and not subject to decomposition. The question of cost could only be tested by lengthened experiments carried out on a large scale. He himself was awaiting with interest the results of the Salford experiments, which would determine the economic value of the process. As to the process yielding an innocent effluent, rapid subsidence and easy filtration, there could be no doubt.

Mr. CASSAL asked in what parts the results given in the paper were stated?

Mr. WORTH replied that they were in parts per 100,000.

Mr. CASSAL continued that in that case the results were certainly remarkable, so far as reduction of organic matter was concerned. It had been asserted by Mr. Webster that the crucial test of a sewage process was the reduction of the amount of organic matter in solution; but short of the *beau idéal* of practically complete removal, such reduction was of minor importance, since there would still be enough organic matter to putrefy and cause a nuisance. The only crucial test which could at present be applied to so-called innocuous effluents on the large scale in any given place, was that of turning the effluents into a river and observing the results. Mr. Fletcher and the reader of the paper had stated that the effluent produced by this process was an "innocuous" one, and he had no reason to doubt the assertion. But if it were so, he would be glad to know upon what grounds so important a statement had been based. The sewage treated originally contained putrefactive and probably disease organisms, and such organisms were either not present in the effluent or, being present, were not capable of producing their specific effects. If this were so, then the result obtained was so important as to put any reduction of the organic matters in solution—short of complete removal—entirely into the shade. It was obvious to anybody who had had to do with sewage that it must be treated in some way before it was either applied to land or run into a stream. Irrigation with raw sewage, except under very special circumstances, was most objectionable and highly dangerous. Like Mr. Sillar, he would be glad to find that the process under consideration was one which would go far towards attaining the end which should be kept in view; but they had yet to learn that the effluent it produced was absolutely innocuous when turned over a sewage farm. So little was the necessity of treating sewage understood, that in a paper recently read before the Society of Arts, it had actually been suggested that the sewage of London should be taken in a conduit from Crossness and Barking to the sea, and there discharged. That would mean an immense quantity of untreated sewage flowing for some 70 or 80 miles at the rate of about one or two miles an hour; and he could only say of it that no more monstrous idea had ever been put before the public even in connexion with the sewage difficulty. Few things could be worse, from a scientific point of view, than the method at present followed in London, which had not succeeded in producing anything except a costly nuisance in the Thames. The case of London afforded an illustration of the fact that most sewage processes must be judged by the effects produced in a reasonable time after the effluent had been discharged into a stream. When Mr. Webster had carried out experiments on a scale sufficiently large or in a manner otherwise decisive to prove that his effluents and sludges were innocuous, he would have taken the only step necessary for forcing his process on the most sluggish of authorities. Mr. Webster had stated that he was in possession of favourable reports from various eminent authorities. In regard to most reports upon questions of this kind, it was necessary to go through them very carefully, and to be able to read between the lines in order to have a clear idea of what their authors had in their minds when they wrote them. It was unfortunate therefore that the reports were not before the meeting. The greatest mistake that could possibly be made in connexion with the sewage problem was that of supposing that corporations could make money out of it. The only way of dealing with sewage was to get rid of it without producing a dangerous nuisance, and in the most economical way that existing circumstances would permit, regarding as the true economy that which placed the health of the community above all other considerations.

Colonel JONES said that the process before the meeting was not new to him, as Mr. Webster had read a paper on it before the Institution of Civil Engineers about a year and a half ago, and illustrated it with experiments on a fuller scale than he had shown that evening. On that occasion he was astonished at the greediness with which a scientific body of men, accustomed to the sewage question for many years, jumped at electricity. It was a quality of human nature to like anything that was magical and startling, and that would account for the reception which the process had met with on the occasion he had referred to as well as by the present meeting. Having been grinding away at the sewage problem for the last 20 years, he himself approached the subject with more caution, and was not very much startled by what he had seen. If he were given a bottle of London sewage, he would merely shake it up violently, and in a few minutes they would see the deposit going to the bottom just as it had done in the experiment made by the reader of the paper. It might be said that he was not a chemist; but he had seen Dr. Tidy do the same thing in the witness-box. It must be remembered that aeration had a great deal to do with sewage treatment. If one took a bottle half filled with sewage and half with air, and agitated it thoroughly, somehow or other a disturbance was created, and in about 20 minutes a great deal of matter went down. That simple effect of deposition was taken credit for by all the patent sewage precipitation people. They put their pinch of lime, 3 grains or 3·7, into a gallon of sewage, agitated it, and then claimed that the deposition was the effect of the 3 grains. Let them try it on the sewage that had stood stagnant for 20 minutes. They did not do that, but they compared the analysis of their effluent with the raw sewage which contained all the matter which by 20 minutes' stagnation would go to the bottom. Was it scientific, he would ask, when a thing was brought to you for analysis, of which more than one cause might have produced the effect, to attribute it to one cause off-hand, or should not one try and eliminate all save one agency. He contended that if one wanted to try the comparative merits of Mr. Dibdin's 3·7 of lime and 1 of iron and this electric process, or any other, one ought first of all to give the sewage some 20 minutes' stagnation, and then compare the analysis of the supernatant sewage with the effluent of the processes in question applied to the same supernatant sewage. He thought it important to consider this view, because during all the years that people had been fighting over precipitation processes, they had neglected all that could be done by simple deposition; and that view had been equally neglected in all the blue books on the subject, until the appearance of the excellent report of Lord Bramwell's commission. That was the first time that simple deposition was officially noticed, and it was referred to in the carefully worded conclusions which the Board of Works ought to have carried out, in the following words: "after the separation of the solids by simple deposition or precipitation."

Mr. DAVID HOWARD thought that the views put forward by the last speaker had a bearing which should not be overlooked. Time was an important element in the question, and if only the electrolytic process would aggregate the suspended matter and cause it to deposit faster than would be the case where merely allowed to stand, it would be valuable on that account alone. He did not share the views of those gentlemen who expected to find sewage anything but a nuisance; but if it was possible by this process to get a rapid deposition of a sediment that could be dealt with practically, then he believed that the sewage problem was solved, as far as in this world of trouble one could hope to solve it. One could not hope to get rid of all the organic matter, nor to obtain an effluent fit to drink.

Dr. R. MESSEL said that, assuming Sir Henry Roscoe's report to be borne out in practice, the question seemed to resolve itself into one of cost, and upon that point it was difficult to form a reliable opinion in the absence of further information—the more so as, if the process mainly depended on oxidation, electrolytic oxygen or chlorine was the most expensive form in which those chemicals could be employed. It would therefore be highly interesting to have some more

information both from an electrical and a chemical point of view. He would also like to know whether cast iron answered well for the electrodes.

Mr. WORTH answered in the affirmative.

Mr. CASSAL wished to explain that he did not intend to say that the *beau idéal* of sewage treatment was to remove the whole of the organic matter in solution until a water equal to distilled water in organic purity remained. His object was to convey that such effluent should be freed from organic pollution to such an extent as to render it equal in purity to the stream into which it was to be discharged.

Mr. A. P. TROTTER had gathered from the reading of the paper that the flow of the sewage would be at the rate of about 16½ ft. per minute, which would allow about 12 minutes action for the whole process. He would like to ask whether that was correct, and also what time was allowed for the subsidence?

Mr. C. C. HUTCHINSON regarded the question of sewage treatment as being altogether a practical and economic one, and mainly one of cost. However perfect a process might be from a scientific point of view, it was well known by everyone who had any experience of the sewage question that as soon as it came into practical operation the best possible results became subordinated to questions of cost. He did not rise for the purpose of criticising the results in the rationale of the elaborate process before the meeting. With the amount of information which the author had given them, accurate criticism was impossible and out of the question. They had no figures, and hence they could not really say whether the electrical process came within the range of practical politics, if he might use such a term in connexion with sewage treatment, or not. He would like to ask the reader one question with a view to elucidating the question of cost. He had told them that for a flow of a million gallons per 24 hours, power equal to 37 indicated horse-power would be necessary. Was that 37 indicated horse-power to be taken at per hour in the usual way? And was the treatment of the Salford sewage to take 400 indicated horse-power reckoned in the usual way for cost per hour? Perhaps Mr. Worth would answer those questions at once.

Mr. WORTH replied that it was per hour.

Mr. HUTCHINSON, continuing, said that that being so, the figures given for the production of 400 horse-power for 24 hours were remarkably low, and, in his opinion, quite inadequate. He had had some experience connected with the production of power, as no doubt many of the members present had, especially Mr. Newlands, and they would doubtless be able to support him when he said that if a horse-power could be produced on that scale much, if anything, under 1*d.* per indicated horse-power per hour it would surprise him. If 400 indicated horse-power were needed for the treatment of 10 million gallons of sewage per day of 24 hours, that would come to something like 400 pence per hour, say 33*s.* per hour, which for a day would be 40*l.*, and for a year about 14,600*l.* for power alone. On the other hand, if the cost of power were taken at 1½*d.* per horse-power per hour, a figure more often the case in practice with ordinary appliances and attention, the cost of power would become 21,900*l.* per annum, added to which would be the cost of sludge disposal, &c. If to that they added the cost of the 500 tons of iron which was to be converted into the active iron salt, the cost of the treatment of Salford sewage would be brought up to something like 24,000*l.* per annum on the highest estimate and 17,000*l.* on the lower scale. Now, it was well known that sewage could be treated at a total inclusive cost of about 1*s.* per head per annum on the population. This would make the cost of the treatment of the sewage of Salford about 15,000*l.* per annum, including everything. He was aware that the value of any particular sewage process had reference not only to the actual results obtained, such as were shown on the table before the meeting, but also to the location of the particular works. If the effluent from the Salford works was to be turned into such a large stream as the Ship Canal, a very rough treatment would be ample, and so long as suspended and

offensive introgressive matters were removed, absolute purity of effluent was not requisite. So far as Salford was concerned, what they had to consider, therefore, was whether the Webster process would yield better results as regards cost alone than any of the other well-known processes, and if it did not compare in cost, he should like to know in what would the advantage of the process consist? It seemed to him that in the case of such a town as Salford, other things being equal, the only point upon which the Webster process could show any advantage was of cost. The A.B.C. process alluded to by Mr. Sillar was very good as a treatment process; but whilst thinking it gave good results as far as purification was concerned, he did not, like Mr. Sillar, claim that it was a perfect panacea for the sewage nuisance, or that it would yield the users of it large, or indeed, any profit; but he did say that he believed that the sewage of Salford could be treated by the A.B.C. process at a cost of something like 15,000*l.* per annum. He would like to hear from Mr. Webster whether he claimed that his process would yield better results at Salford than could be got by the A.B.C. process, or by any one of half a dozen other well-known processes equally as good, and if so, whether he based his claim on anything like equivalence of cost?

The CHAIRMAN, before calling on Mr. Worth to reply, observed that it was interesting to note that several of the members who had taken part in the discussion had borne testimony to the salutary efficacy of certain salts, chiefly salts of iron, which had long been popular in connexion with sewage treatment. The main point, however, to which he would direct Mr. Worth's attention, was the economic aspect of the question. As so many speakers had referred to that point, he trusted that it would receive the very specific attention of the author of the paper, to whom, as he was absent, notes of the discussion would be sent.

Mr. F. G. WORTH said that he would do his best in Mr. Webster's absence, and as his substitute at the eleventh hour, to reply to the various points raised during the discussion, and if he was unable to reply clearly to any particular questions, he would undertake that Mr. Webster himself should do so if the members concerned would submit them to him in writing. He referred especially to one or two chemical queries, as to which he was bound to admit that he had not the proper knowledge to enable him to reply satisfactorily. The subject was a complicated one, and he must confess himself to be as unable to define the exact chemical reactions which take place as many eminent chemists had declared themselves to be. But he would consult the inventor.

Dr. Bischof had spoken about the presence of organisms, and he should state at the outset that the electrical process did not claim in actual work to destroy the whole of the organisms present in sewage. That aspect of the question had been very seriously considered; in fact it was during Mr. Webster's bacteriological study of the problem that he (Mr. Worth) first became connected with the process. He was then living in Paris, and had the opportunity of going to M. Pasteur's laboratory. He took some samples of treated sewage both to M. Roux at Pasteur's and to M. Marié-Davy for examination. He was told that the electrical process had succeeded in reducing the number of organisms from something like 5,000,000 per cubic centimetre to 600, but that notwithstanding this reduction there might be several millions again by the following day. From that moment he had felt that it was useless in actual practice to devote attention to the bacteriological aspect of the question, the more so as M. Roux had remarked that bacteriologists were as yet only on the threshold of the science. In fact most bacteriologists would, he thought, admit that they could not say what organisms were beneficial and what harmful; and therefore by destroying all they might do positive harm.

In reply to Mr. Sillar's remarks as to the existence of the A.B.C. process for a quarter of a century, the accuracy of which he quite admitted, he would merely say that the Electrical Company was as yet quite young. It was feeling its way, honestly and straightforwardly, as one gentleman

had said; but it had not yet got to that stage at which they could say that they had a town which had been working for a long time with practical results. He hoped, however, that they would soon be in that happy position, and long before 25 years had passed he trusted the Electrical Company, more fortunate than Mr. Sillar, would have proved its case otherwise than by adoption in one town only; at any rate if they had not, he should long before that time expired have nothing more to do with the electric process. He could only compliment Mr. Sillar on the pluck with which he had stuck to a process which so many had condemned. He said that honestly, for he felt that Mr. Sillar's courage deserved more success than it had met with. Mr. Sillar had asked a question with regard to the running off of the effluent without disturbing the sludge. They had always been able to do that; further, there could be no question as to the process removing a very large percentage of dissolved organic matter as well as matter in suspension. But as he wished to tell them the defects of the process as well as its advantages, he would admit that with certain sewages they sometimes got iron in a very finely-divided state in the effluent, and in that case a little organic matter was sometimes hung up with the iron, which they had to get rid of. In certain sewages that might be a source of annoyance. Of course the electric process by itself might not be a panacea for everything. The Electrical Company would have to deal with acid sewages, and sewage containing sulphates, and so on. In such cases, after treating the sewage by electricity, they might, to produce a clear effluent, have to pass it through some filtering material or otherwise treat it in a manner covered by the Webster patents. He would, however, ask members to bear in mind that the sewage was practically purified after electrical treatment, and that they simply relied on filtration, where considered necessary, as a mechanical agency. As to the disposal or utilisation of sludge, that was a delicate question, and in big towns a very disagreeable question. He held that it should be shelved as well and cheaply as possible, but that it must be done at any necessary cost. He did not believe in the manurial value of sludge or in obtaining value from farmers for it. One might, as Mr. Sillar had done, sell 10,000 tons of it in 25 years; but in the case of such towns as London and Salford that quantity would be a mere nothing. In the case of London and Salford, few agriculturists were at hand to take the sludge; and if there were enough, they would only require manure during about three months of the year. During the rest of the year the sludge would have to be stored, and if rain got to it during that period what little ammonia it contained would go off. Considering the cost of carriage, &c., he personally thought it would be much better for farmers to buy sulphate of ammonia, nitrate of soda, and phosphates. But if sludge had any manurial value, the small addition of iron which the electrical process put into it would, for many soils, increase that value. It was possible, too, that it might prove to be valuable in another way, if the experiments which were being carried out succeeded. Those experiments consisted in filter-pressing the sludge, and then carbonising it to such an extent as to produce the red magnetic oxide shown in one of the phials before the meeting, or carrying on the carbonisation far enough to produce the black magnetic oxide, a sample of which was also shown. If those experiments were successful, Mr. Webster would communicate the results to the Society at a later date. It was impossible to compare the effluent produced at Kingston with that which was obtained by the electrical process at Salford, the two sewages being so different in character. The only way of arriving at a comparison of the two processes would be for both of them to deal with the same sewage at the same time. With regard to the effect of the effluent on fish life, he paid very little attention to that point; fish were shown in most effluents. An alderman who visited the electrical works, on being shown some fish alive in their effluent, said: "Well, what does that prove? When a boy I always got most fish in the dirtiest water." The fact remained that fish did live in the electrical effluent. He thought he had answered most of Mr. Sillar's remarks, and he thanked him for the spirit in which, as a competitor, they were made.

Mr. Birch had asked for information with respect to the cost per head of population for completely treating sewage by the electric process. He was sorry to say that at the present moment he was not in a position to give the whole of the data. At Salford the electrical process was engaged only in producing a satisfactory effluent, the sludge was considered to be a separate and subsidiary question. The company had asked to be allowed to carry out experiments with the sludge, but they were met with the reply: "We do not think such experiments necessary. We shall always have sludge, though less by your process than any other, and we do not wish to waste time on them at present." For that reason only he was unable to give the information which Mr. Birch so naturally asked for. So far as they could give figures, both Mr. Webster and himself were willing and anxious to do so. But sewages differed in the treatment they required, and it was best therefore to deal with a case in which the experiments had been carried out as at Salford, not by the company alone, but by a corporation who had controlled the whole thing, and whose report would be issued shortly. Perhaps on that account the reading of the paper had been somewhat premature, and it might have been better to wait until the report was actually out, and so be able to give other people's figures, which might naturally be considered more reliable than any of those which he could bring forward. Mr. Webster had felt, however, that it was due to the Society that the paper should not be further postponed, and had it not been for his illness, which he had fought against to the last moment, the meeting would have had full replies on the chemical points raised.

Mr. Cross had put some chemical questions which were quite beyond his (Mr. Worth's) power to answer, but he was sure that Mr. Webster would be happy to do so if Mr. Cross would state them to him.

Mr. Newlands had spoken in such a manner as to leave him absolutely nothing to say in reply, except to thank him for his reference to certain patents which he would take the first opportunity of looking into; for, as Mr. Newlands had said, everyone can learn something from other people's patents.

He must also thank Mr. Fletcher for his remarks; his report was the result of independent investigation, and it was all the more satisfactory therefore to find him corroborating everything that Mr. Webster and himself had said.

Mr. Cassal had made a speech which he would be glad to answer more in detail than time would then permit. He had raised the question of organisms, and on that point he (Mr. Worth) had expressed his personal views in replying to Mr. Bischof. With regard to taking out the whole of the organic matter in solution, of course Mr. Cassal meant the whole of the putrefying matter, for to take out the whole would be of no great advantage; and it was very difficult to decide what was the exact quantity that should be taken out. A pertinent question had been asked as to the meaning of the term innocuous, and on what it was based. Chemists and others could only do what was humanly possible to ascertain whether the effluent was innocuous or not. They had taken effluents produced on a working scale from different sewages; had kept them in stoppered bottles and in unstoppered bottles; had mixed them with water and kept them without water; and none of them had gone bad. He would expect that if they ran such an effluent as that produced containing a small proportion of organic matter into a stream, the oxidising action would rapidly take away the objectionable portion of the effluent. With regard to sending sewage to the sea, that was rather outside the limits of the question; but he quite agreed with Mr. Cassal that nothing could be much worse than the system at present followed in London. The sewage had to be dealt with and got rid of somehow, and though by electricity they did not profess to do it so economically as some processes professed to do, they did claim to do it efficiently and at a reasonable cost. Neither did they profess that their effluent was to be regarded as a drinking water; at the same time it was a thoroughly harmless effluent, and independent chemists had stated that after submitting it to the severest tests there were no signs of after-putrefaction. If anyone else could do better,

Mr. Webster and himself would have no course but to retire from the field, for their continuance in it could only be maintained by commercial success. He might add that the full reports of the chemists were open to inspection to anyone desirous of fair investigation.

Colonel Jones had made a characteristic speech, repeating what he had seen 18 months ago, when the electrical process was in its infancy. But it must have been a very promising child for the engineers to jump at it as Col. Jones had said. The experiments shown that night were certainly not on so large a scale as those shown on the occasion referred to by Col. Jones; but he hoped that they had been sufficient for the purpose, especially as they were now backed up by practical results. He was sorry to see that Col. Jones had left the meeting. If he were still present, he would be happy to submit a sample of sewage to the test he had proposed, asking Col. Jones, or any other gentleman who would now take his place, to shake it up for 20 minutes and compare the result. The analyses of the effluent were not compared with unsettled sewage only, but also with settled sewage. It was to be remembered that sewage must be taken as it came, it being generally impractical on a large scale to have separate tanks for it to settle in before treatment. To determine chemically what degree of purification any process had attained, one must compare its results with settled sewage. That had been done in their case.

In reply to Mr. Howard's inquiry as to whether the sewage deposited quicker by the electrical method than by mere standing, there could be no doubt that it did. If sewage were allowed to stand for 24 hours, there would be no material difference effected; practically no organic matter in solution would be removed. If it stood for any length of time it would become as clear as the effluent before them, but that would prove nothing.

Mr. Hutchinson's criticism of the process would be serious, if he had not unintentionally erred on the side of exaggeration. He had said that all other points of the process would be subordinate to the question of cost, and he had criticised the figures given for the production of the power required at Salford. But he would remind Mr. Hutchinson that the figures for horse-power would not be the same everywhere, but would vary with the sewage. Salford, for instance, would require more per million gallons than London. Mr. Hutchinson estimated the cost of producing an indicated 400 horse-power per hour at 16,000*l.* per annum. The company's engineers had worked it out themselves, and their estimate was before the meeting. Perhaps their figure for coal was low; but with the highest class of electric machinery they had a right to expect that they would obtain results as good as had yet been got. They could, he thought, calculate on using not more than 2 lb. of coal per indicated horse-power per hour. If they were wrong, if the actual quantity would be 3 lb., then the estimate for that item must be increased by one-half. But he was told, and he believed that he could have a guarantee on the point, that it could be done with 2 lb. of coal.

Mr. HUTCHINSON, interposing, said that the cost for fuel was only a small portion of the total cost for horse-power. If they reckoned their fuel at 2 lb. per horse-power, they would have to use Welsh coal, which at present was 18*s.* per ton. And if to that they added the charges for wear and tear of machinery, interest on cost of plant, labour, &c., they would find the cost amount to quite a penny per horse-power.

Mr. WORTH said not; but there was not much use in continuing the discussion on that point then. It would be best that the figures verified by the engineers at Salford should be put before the members. At present the figures which he had given were the estimate of the company, and he would stand by them. To them, however, must be added the loss for consumption of iron, which, at the rate of 3 grains per gallon, would equal 690 tons per annum, worth 2,760*l.*; and of course there were sundry other items of expense. As to the advantages of the electrical over other processes, and its superiority to chemicals, he thought it best for this question to be answered by the independent reports obtained and those to be submitted.

Dr. MESSEL remarked that they would have to renew their iron plates long before they were completely worn out.

Mr. WORTH admitted that, and said that the question was, how soon? They would certainly last several years. Cast-iron plates were used at Salford.

Mr. HUTCHINSON said that, at 3 grains per gallon, the loss would be 740 tons per annum.

Mr. WORTH replied that he adhered to 690 tons, which he thought was correct for 10 million gallons a day. Dr. Messel had said that they had no information as to cost. They had information, but it was the company's, and he thought that it was best that the information should come from others.

In answer to Mr. Trotter's question, the rate of flow was difficult to give off-hand in feet per minute. The rate of flow was about 3,000 gallons per hour with a shoot 18 in. wide. The time of subsidence varied, the maximum being three hours. A continuous flow was, he thought, better than intermittence for electrically-treated sewage. With regard to the Chairman's closing remarks, he could only repeat that he would get Mr. Webster to put before the Society, as early as possible, the estimates made by independent men, as well as the full chemical reports, which would be far more valuable than any he could lay before them at that moment. He would conclude by thanking the members for the very courteous reception they had accorded to him as Mr. Webster's substitute, and much regretted that he had only had a few hours to put Mr. Webster's rough notes into a readable form, which necessarily caused the paper to be incomplete on many interesting points. In consenting to act at such short notice as Mr. Webster's substitute, he was animated by the desire not to disappoint the meeting altogether, and claimed their indulgence for present shortcomings.

At the close of the discussion Mr. WATSON SMITH exhibited a new form of india-rubber stamp enclosed in a locket, the lid of which closing upon a spring handle attached to the stamp, presses the latter upon a pad. The stamp is thus always ready for use, and whilst by gentle pressure upon paper it gives a sharp and clear impression of the benzene ring in single lines, by stronger pressure alternate double and single lines appear. By gentle pressure twice performed and at points in close juxtaposition the naphthalene ring is delineated. This convenient aid to the writing of abstracts, notes, papers, &c., on aromatic organic chemistry was sent for exhibition by, and is the invention of, Mr. C. S. S. Webster of Bristol.

Notices of Papers and Communications for the Meetings to be sent to the Local Secretary.

*Meeting held on Friday, 7th November 1890.*

MR. IVAN LEVINSTEIN IN THE CHAIR.

THE CHAIRMAN called attention to the resolution passed by the Committee with regard to discussions being held at the ordinary monthly meetings previous to the reading of papers. It was thought that discussions not exceeding half an hour would afford a means to the members of interchanging their ideas on those subjects in which they were more especially interested.

The CHAIRMAN introduced for discussion—

"AMENDMENTS ON THE PATENT LAWS AS SUGGESTED BY THE CHEMICAL COMMITTEE OF THE MANCHESTER CHAMBER OF COMMERCE."

THE CHAIRMAN said it would scarcely be necessary for him to read through the whole of the report of the committee, but he would lay before them the proposals which the Manchester Chamber of Commerce intended to introduce to the House of Commons next session, and which he hoped might receive the support of our Section, as representing the chemical and allied industries of Lancashire. The report and the proposed amendments had not only been approved by the Board of the Manchester and also of other Chambers of Commerce, but several members of Parliament had also expressed their sympathy with them and promised their support. He would read to them the following letter which he had received from Sir Henry Roscoe:—

"I have carefully read through the draft report of your committee to the Manchester Chamber of Commerce. The subject is one in which I feel much interest, and your report has my hearty sympathy. I quite agree as to the necessity of some change in the law of chemical patents, as you point out. Section 18 opens the door to abuses of a serious character, and the proposals of your committee seem to me to meet the difficulty, inasmuch as they do not act as restrictions to honest inventors, but only prevent patentees from abusing their privileges, &c. If the Chamber decide to take action in the matter I need scarcely say that I shall be glad to give it every assistance in my power in the House of Commons."

THE CHAIRMAN said it might interest the members to know that the Chemical Committee of the Manchester Chamber of Commerce has at present under consideration the new tariff proposed by the French Government, as far as chemical products came into question. The proposed tariff was by no means a general advance on the duties at present charged and compared with other products. The French Government had wisely taken care not to ballast too heavily chemical produce, which, to a large extent, served as raw material in the production of textiles. Still, in some few instances, the proposed increase was such as to make import to France from England prohibitory. For instance, alum (ammonia or potash) and sulphate of alumina, which now paid approximately 7s. 4d. per ton, were proposed to be taxed at 30s. 6d. per ton, which was more than four times the duty at present charged. There was, further, an increase of about 25 per cent. on iodide of potash and ammonia. Oleic acid, which was now free, would pay 1l. per ton; the duty on stearic acid was more than doubled, and oxide and carbonate of lead, cobalt salts, calcium citrate, which were hitherto exempt from duty, were proposed to be charged respectively per ton, 16s., 14l., and 3l. There was also an enormous and absolutely prohibitory increase on salts of quinine. On the other hand there was proposed a reduction of duty on the following products: Bromine and its salts, oxalic acid, borax, aluminium, chloride and chlorate of potash. Out of 117 chemical products there would be a change in the proposed tariff in the case of 16 products, whilst 101 products would be taxed as hitherto. The intermediate products from coal tar used in the manufacture of coal-tar colours, such as nitrobenzol, carbolic acid, and those not enumerated, were under the present tariff free; whilst under the proposed tariff

there would be a duty of 6*l.* per ton, a move no doubt intended to further stimulate the development of the coal-tar industry in France. He only intended to give them a few illustrations of the proposed tariff. The Chemical Committee of the Chamber would be pleased to receive any suggestions or observations from members of the Society. The committee was at present engaged in preparing a comparative table of the duties at present charged, and those proposed by the new tariff. Finally, he again wished to urge upon them the advantage of joining the Chemical Section of the Manchester Chamber, which was charged to look after the interests of those engaged in the chemical and allied trades.

The CHAIRMAN then referred in detail to the report (see this Journal, June 1890, 676).

The CHAIRMAN proceeded to say that he thought it was very desirable that the meeting should support the proposals of this Section of the Chamber of Commerce.

MR. CARPENTER wished to know whether, under section 22, any case had been presented to the Board of Trade, asking them to fix a licence for any patent taken out by a foreign country, or if any application had been made for a licence on behalf of a manufacturer who finds himself unable on account of the foreign patent laws to work the process he has found out.

MR. WM. THOMPSON was of opinion that any one taking out a patent should be called upon to work it within a certain time, otherwise it would become invalid.

MR. GRIMSHAW thought the two most important points for consideration were section 18, and the one relating to foreign patents in this country, otherwise we should be handicapped in the industrial race. He had introduced this matter at the council meeting in London, and he was sorry to say that the members declined to entertain it. If they wished to make the alterations suggested by the proposals brought forward by the Chairman they would have to put into motion a very sluggish body—the Commissioners of Patents—who knew nothing about the interest which the industrial communities at large take in these matters, and the only way to get them to move would be by repeated agitation, inasmuch as those who were at the head of these Departments of State were not technical in the sense of being acquainted with the details, and consequently the one fact which has any weight with them is public opinion.

The CHAIRMAN in reply to Mr. Carpenter said, as far as he knew there had been hitherto no test case submitted to the Board of Trade under section 22. One part of this section, viz., "The patent is not being worked in the United Kingdom," is absolutely meaning less in its present form. No doubt Legislature intended to compel a patentee to grant licences in case he does not work his invention in this country, but without a proper definition of the word "worked," the principal object of this part of the section has been defective. Under this section a patentee is neither bound to work on a manufacturing scale nor is he tied to any time. He may either work his invention in his parlour or in his stable or any other sham way, or he may commence to work his patent a few weeks before its termination. The Manchester Chamber has also at present under consideration this important section, and he would not fail to communicate the result at a future meeting.

The following resolution was then put to the meeting and unanimously carried:—"That this meeting approves of the proposals for amendments of our Patent Laws as submitted by the Chemical Committee of the Manchester Chamber of Commerce."

## ON RIVER POLLUTION, AND THE PURIFICATION OF SEWAGE BY ELECTRICITY AND OTHER METHODS.

BY J. CARTER BELL, A.R.S.M., F.I.C.

As the consulting chemist to the River Irwell Conservancy Committee appointed by the council of the county borough of Salford, it has been my duty during the past two years to give special attention to that most interesting and important problem, "the purification of sewage, and the prevention of the pollution of rivers." The following resolution of the Salford council will clearly show the immediate cause of my investigations:—"Resolved, That in view of the approaching completion of the ship canal docks, and the consequent impounding therein of the waters of the Irwell, the River Conservancy Committee be instructed to present a report to the next meeting of the council, showing what improvement in the condition of the river has been attained during the past two years, and further showing what prospect there is of such purification as will render the water fit to be impounded without serious detriment to the public health." The Conservancy Committee, in reporting in accordance with the instruction of the resolution, remark:—"Your committee are pleased to find that the anxiety they have felt for some time past with reference to the condition of the river, not only in view of the early completion of the ship canal, but on the broader grounds of the sanitation of the borough as affected by the condition of the river, is shared by the council."

It is this larger question, viz., the "broader grounds of sanitation," which renders the experience of the Salford committee of use to other corporate bodies, and which forms the object and justification of my paper.

As will be readily understood, it has been my duty to examine many hundreds of samples of river waters, crude sewage effluents, &c. It is not my intention to inflict upon the Society a mass of figures. I shall confine myself to giving an average of the various waters, &c. brought under investigation. I wish to mention that the whole of the samples submitted to me were taken by the inspector acting under the direction of the River Irwell Conservancy Committee of the county borough of Salford.

I suggested to the committee that samples of water should be taken every week from the Irwell as it entered and left the borough of Salford. My idea was that we should have some record to show if there was any improvement in the state of the river. These weekly samples have been taken for something like 18 months. As I was anxious to obtain a standard of what the Irwell should be, I asked the inspector to take a sample of water before it had passed any works. This was done, and the total solid matter at Irwell springs is only 8 parts in the 100,000, and this sample was taken at the most unfavourable time of the year, when the water was charged with suspended matter equal to 2 parts in the 100,000. But immediately on passing the first works the total solids and suspended matter increased very rapidly, total solids 37, suspended 7, and so on until it reaches the borough. The variation of the total solids and suspended matter is very remarkable, for in one month it may be as low as 30, and at another time mount up to over 100 parts in the 100,000.

This variation will, to a great extent, depend upon the rainfall, the total solid matter being high in times of drought and low in the rainy season; but this rule does not always hold good. For instance, samples of water were taken on November 7, 1890, from the Rivers Irwell, Irk, and Medlock, at a time of flood, and the amount of total solids and suspended matter is given below:—

	Parts per 100,000.			
	Irwell as it enters Salford.	Irwell as it leaves Salford.	Irk.	Medlock.
Total solid matter ..	80	97	81	78
Suspended matter ..	57	68	40	27

This enormous quantity of suspended matter will be a serious inconvenience to the Manchester Ship Canal Company, and therefore it is imperative upon manufacturers to keep their solid matter out of the river.

I thought it would be interesting if a sample of water were taken on some Sunday, as I had the impression that the river would be clearer on that day than on any other day of the week; but, strange to say, the river was in a worse state than on any day during the 18 months upon which samples have been taken. This particular Sunday was July 7, 1889. The total solid matter was 106 as the river entered the borough, and 93 when it left. These very high numbers may be due to certain manufacturers who make a point of having a general "clear up" on the Saturday, and getting rid of all their objectionable matter by passing it on to their neighbours.

The question may be asked, who are the great polluters of the river? Unfortunately, their name is legion.

There can be no doubt that the paper-makers are responsible for an immense amount of pollution, both solid and liquid. The liquid, consisting chiefly of the resinous matters from the straw and esparto used, dissolved in the alkali employed. This is undoubtedly a difficult matter for the manufacturers to contend with, as the plant necessary for the utilisation of this refuse is very expensive, and not altogether satisfactory, owing to the enormous quantity of water to be evaporated, and the peculiar properties of the residue.

The solids from a paper mill are also very large, and this pollution consists of the debris of the materials used, minute portions of paper and mineral matter escaping from the washing machines, the dregs from the bleaching-powder and caustic pans. In well-conducted works the second item mentioned is reduced to a minimum, manufacturers being fully alive as to its value. The matter passing from the machines may be considered fairly inert.

The bleaching-powder and caustic dregs, however, constitute a most serious source of pollution, and the amount produced in the various paper works using the Rivers Irwell and Roach must be something like 150 to 200 tons a week.

The whole of this material can, and must be kept out of the river; this serious pollution can be prevented by very simple means, indeed several large works are already making attempts to deal with this refuse by constructing large settling tanks, into which the dregs are collected and settled. In one works which I visited, this solid matter was collected, made into bricks, then dried and burnt in a kiln, and then sold for the manufacture of cement, and as this burnt residue consists largely of soluble silica, it would have the tendency to form a good cement.

This method of collecting the solid matter in tanks, in the absence of anything better, may be effectual, if loyally carried out, but as the sludge produced is very bulky and difficult to deal with, I am afraid the river becomes after all the common settling tank; and it has come under my own observation where tanks with suitable plugs have been used, and at some convenient season the whole of the solid matter is shot into the river.

I may here remark that in days gone by, when large profits were made from the production of paper, manufacturers did not consider it necessary to attend to the waste product of their mills. The habit of waste has become a confirmed one, and it appears to me that unless compulsion is brought to bear upon these manufacturers to keep their refuse out of the river, it will not be an easy matter to teach them, and to prove that this prevention of the pollution of the river by paper-makers is not an Utopian idea. I have had a process brought under my notice, by which these solids can be wholly kept out of the river in a cleanly and convenient manner, all connexion between the settling tanks and the river is cut off, and which makes it impossible for the manufacturer to draw the plugs and send the refuse into the river. Instead of this easy and

wasteful plan, the solids are removed in a portable form, and the valuable materials, now lost, are again utilised. There is no doubt that for the expenditure of a few hundred pounds, sufficient saving could be effected to return a very handsome dividend upon the outlay.

With such a process, which is as ingenious as it is simple, paper-makers will be enabled to relieve the rivers of this enormous amount of solid matter with considerable advantage to themselves. I understand that the process of which I speak will shortly be at work in one of the largest mills in the neighbourhood of Bury.

My attention has also been directed to an ingenious invention of one of our members, Mr. W. Birch, of the Milton Iron Works, Lower Broughton, Manchester. This is described as an "improved continuous filter," and is intended for the treatment of large masses of impure water. It consists essentially of an endless band of thick felt carried over suitable rollers; the water conducted on to the surface of the felt passes readily through the same, leaving the suspended matter coating the surface of the felt. The felt, in its movement over one of the carrying rollers, is suddenly compressed by a counteracting roller, and this sudden compression of the water contained in the pores of the felt causes the coating of suspended matter, the sludge, to be driven off into a receiving box. The action of the machine is very simple, and from what I have seen of its working I conclude that it will answer to the claims of the patentee. One machine, costing 200*l.*, will filter from 100,000 to 150,000 gallons per day, and by its use filtering and settling tanks are entirely dispensed with.

It has been found that on the majority of days, when the river leaves Salford it is more impure than when it enters the borough.

I asked the inspector to obtain samples of water from every works in the borough draining into the Irwell, and the following figures, in parts per 100,000, will give you some idea of the amount of suspended matter that is being discharged into the river: 456, 246, 154, 282, 135, 159, 477, 135, 134, 264, 376, 590, 127, 184, 148, 125, 131, and 12,280.

These heavy numbers must not be all laid upon the backs of the paper-makers, for some of the sinners in this respect of pollution are india-rubber manufacturers, dyers, soap-makers, brewers, and sundry other firms; there is one number which you may think is an error, and that is 12,280. This solid matter consisted of fat, glycerin, and alkaline salts. It is difficult to believe that a manufacturer can be so reckless as to throw his profits into the river in these days of fierce competition. I feel certain that this gentleman will thank the River Conservancy for reclaiming him from the evil of his ways. The numbers I have given represent but a very small portion of those manufacturers who collectively are discharging thousands of tons of solid material into the river annually. The River Conservancy Committee of Salford is doing all that lies in its power to purify the river, and to try and bring back once more into the lovely Irwell valley the long-lost crystal streams. Yet it is sad to say in these days of enlightenment, that the committee is met by opposition, in an "Association for the Protection of Manufacturing and Commercial Water Rights." These gentlemen who form this association seem to prefer the waters of Lethe to those clear and crystal streams which flow through Elysian fields; can these gentlemen who form this association justify such samples as I place before you. I am glad to say that there are now more than 40 firms on the banks of the river who are putting up settling tanks and filters, so as to prevent the suspended matter flowing into the river; ultimately this must result in a great gain to the manufacturers, for at the present time large sums of money have to be spent to purify the water before it can be used in the processes of various manufactures. Another reason why the River Irwell is more impure when it leaves Salford than when it enters, is, because it has received the waters of the Irk and Medlock.

## Comparison of Salford sewage with the three Manchester rivers :—

	Parts in 100,000.				
	Salford Sewage.	Irwell as it enters Salford.	Irwell as it leaves Salford.	Irk.	Medlock.
Total solids .....	142	70	85	120	112
Suspended matter .....	15	7	12	26	24
Suspended mineral .....	8	2	3	8	14
Suspended organic .....	7	5	9	18	10
Total solids in solution .....	127	63	73	94	88
Mineral solids in solution .....	106	46	58	72	76
Organic solids in solution .....	21	17	15	22	12
Chlorine.....	38	23	30	29	31
Oxygen absorbed in 15 minutes.....	3.4	2.3	2.8	2.7	2.4
Oxygen absorbed in 3 hours.....	5.8	3.9	4.2	5.4	7.2
Free ammonia .....	1.5	0.24	0.72	1.44	0.24
Albuminoid ammonia .....	0.64	0.29	0.36	0.72	0.51

On comparing the above analyses one need not be surprised to find the Irwell so polluted when it leaves the borough of Salford, for the Irk and Medlock are nothing better than open sewers, and what flows along is about equal to ordinary Salford sewage, and in the future when the history of Manchester is written it will hardly be believed that a people could spend a million of money on a town hall, and yet allow three lethal streams to meander through their midst.

From the pollution of rivers we naturally come to consider their purification, and we thus come on to the sewage-question, and I need not say that this is one of the great problems to be solved. During the last 12 months the authorities in Salford have invited various gentlemen to try experiments at Mode Wheel sewage works, and I thought it would be interesting to bring before you some results of these experiments.

The first is the electrical; this is certainly the most novel of all the experiments which have been tried on sewage.

The electrical process, which is generally thought complicated, is in reality particularly simple; the system consists in passing an electric current through the sewage, which is caused to flow through a shoot or channel in which iron plates or electrodes are fixed, these electrodes being connected alternately with the positive and negative conductors of a dynamo driven by steam or other motive power.

In travelling along the shoot, every particle of the sewage comes in contact with the iron plates, and is then run into settling tanks, where the precipitation takes place.

The treated sewage as it leaves the electrical shoots is practically purified, and is free from danger of putrefactive change, but this effluent though harmless is not colourless. If a perfectly colourless effluent be required absolutely free from suspended matter, filtration is all that is necessary. The exact chemical reactions which take place are not in my opinion clearly understood. I think that the active agent is hydrated ferrous or ferric oxide. The changes which take place are no doubt very complex, rapid change and interchange going on in such a way that definition is almost impossible.

Mr. Webster is, or was, of opinion that hypochlorite of iron is formed, but this I have been unable to trace. It is, however, certain that nascent gases are liberated, such as oxygen, hydrogen, and sometimes chlorine if the sewage were very strong in chlorides. There can be no doubt as to the valuable results obtained by this process; the effluents which are now before you are as clear as spring water. With reference to the sample which has not been filtered, you will notice a reddish suspended matter; this is nothing more than hydrated oxide of iron which in my opinion is really beneficial, for as long as you have an excess of this

material, you cannot have free sulphuretted hydrogen; and time after time when I have been analysing the waters from the Irwell I have found free sulphuretted hydrogen, and I need not say that is one of the principal causes of the bad odours which proceed from the river in warm weather; therefore, to have suspended oxide of iron in the water, though it gives the water an unsightly appearance, is not without some advantage.

In regard to Salford sewage, I can confirm the statements of Sir Henry Roscoe and Mr. A. E. Fletcher, who have both reported on the process (see pp. 1093—1094), though whether the effluent produced would be considered by the authorities sufficiently clear and colourless to be sent into the Ship Canal without some sort of filtration, I am unprepared to say. Whatever process be adopted, I believe the Local Government Board insist on filtration through land, though without specifying the area, and I am certainly clear that a very small area would suffice for producing not only an innocuous but a colourless effluent from the electrical process.

I am, of course, not prepared to go into the question of cost, this mainly depends upon the consumption of coal, where water power is unobtainable, and the waste of iron from the plates; these points we shall shortly be enlightened upon, as the experiments lately carried out at Mode Wheel were subjected to the most searching investigation and control. The experimental works constructed by the Electrical Association at Mode Wheel sewage works were on a scale of operation sufficiently large to demonstrate the system.

The crude sewage was passed through a channel of brickwork 90 ft. long, 4 ft. 9 in. deep, and about 14 in. wide. In this channel were suspended the iron plates which form the poles or electrodes, 364 in number. They were made of cast iron of a common quality,  $\frac{3}{8}$  in. thick, 4 ft. deep, and 2 ft. 8 in. in width. For electrical reasons they were divided into 28 sections, each containing 13 plates, connected by copper strips to a dynamo. The plates were fixed longitudinally in the channel so as to present their edges to the flow of the sewage, and as the space between the plates is five-eighths of an inch, every particle of the sewage in transversing the length of the channel was subjected to the action of the electric current.

The impurities separate themselves in the form of a flocculent mass, which at first is buoyed up to the surface as a froth or scum by the various liberated gases, but after being allowed to remain quiescent in a tank set apart for the settlement of the impurities, they gradually fall to the bottom, and the remaining liquid is the purified effluent.

For dealing with the whole of the Salford sewage, say 10 million gallons per 24 hours, the arrangement would be practically on the same lines as for the experiment, and

the control has shown that its application presents no material difficulty inherent to the process even with such a large volume of liquid. I am informed that the indicated horse-power would not exceed 400 for the whole quantity. The chief outlay would be, probably for cast-iron plates used as electrodes, but they would certainly last from seven to 10 years, according to their thickness. The loss of iron in the experiments was about three grains to the gallon of sewage. I need not say that the sludge by this process is less than by any other, because with the exception of the little oxide of iron, nothing is added to increase the sludge, and when this sludge is dried and ignited magnetic oxide of iron is formed.

So confident are the directors of this company that success must follow their efforts, that they offer to put down all the necessary plant for the purification of any quantity of sewage, and they do not ask for payment until it has been proved that the desired end has been accomplished. I have made many analyses of the effluents, but it would be tedious to give them all, and therefore I have thought it better to give a fair average from each process, and append it to this paper.

The second process is that called the Polarite or International System. In this method the sewage is run along a shoot into a tank, and on its way it receives a small portion of a substance called "ferrozone;" this is composed of sulphate of iron, alumina, and magnesia, together with some fine magnetic oxide of iron.

#### ANALYSIS OF "FERROZONE."

Moisture.....	20.00
Ferrous sulphate.....	16.28
Ferric sulphate.....	6.07
Alumina sulphate.....	22.20
Carbon.....	1.47
Insoluble in water.....	15.20
Water of constitution and other matters....	15.78

When the sewage has been thoroughly treated with ferrozone, the treated sewage is allowed to run into a tank and to remain there for about four hours; at the end of that time most of the suspended matter will have settled, and the supernatant liquid is run on to the filter. This is composed of sand and the substance called polarite, which is a magnetic oxide of iron.

Magnetic oxide of iron.....	54.52
Alumina.....	6.21
Magnesia.....	7.24
Silica.....	24.92
Water.....	6.13
Lime, carbon, and alkalis.....	0.98

This is mixed with sand and put into the filter, about 1 foot in thickness. The purifying power of this filter is very remarkable; it reduces the organic matter about 80 per cent. and even more. At first I was very sceptical about this filter, as I could not understand how this filter could be worked day after day without losing its filtering power. I thought it would be interesting to compare an ordinary sand filter with a polarite one. For this purpose I had two ordinary 9-inch drain-pipes cemented together in an upright condition. One was filled with sand and the polarite mixture and the second was filled with sand alone. Various gallons of sewage, to which 2, 4, 6, 8 and 10 grains of

ferrozone were added. These were passed through the filters in one-gallon lots, and the difference between the two filters was very great.

In the case of the sand filter, the whole of the free ammonia was taken out and converted into nitrates.

#### SAND FILTER.

100,000 Parts.	1.	2.	3.	4.
Free ammonia.....	Nil.	Nil.	Nil.	Nil
Albuminoid ammonia.....	.08	.11	.14	.13

#### POLARITE FILTER.

100,000 Parts.	1.	2.	3.	4.
Free ammonia.....	.03	.02	.04	.06
Albuminoid ammonia.....	.02	.07	.08	.03

The appearance of these two effluents was very marked after passing through the respective filters.

The sand effluent was cloudy, with matters in suspension, while the polarite effluent was bright and clear, and could not be distinguished from spring water by the appearance. The great question is, how long will the filters possess this filtering power? At Acton, near London, the Local Board have these filters at work, and I understand that these filters have been in use for over three years, and some weeks since I visited this place and saw the effluent running away like clear spring water. The following are the analyses of the sewage and effluent:—

Albuminoids.	Acton Sewage.	Polarite Effluent.
Total solids at 212° F. in 100,000 parts	361	77
Suspended matter.....	306	..
„ mineral.....	190	..
„ organic.....	116	..
Solids in solution.....	55	77
„ mineral.....	45	50
„ organic.....	10	27
Chlorine.....	5	6
Oxygen for 15 minutes.....	1.28	0.040
„ 3 hours.....	2.55	0.240
Free ammonia.....	6.10	0.220
Albuminoid ammonia.....	0.70	0.035

Samples of water from the Irwell, Irk, and Medlock were analysed and then passed through polarite filters, without any addition of ferrozone; the following shows the purification effected by the polarite filters:—

100,000 Parts.	Irwell before Filtering.	Irwell after Polarite.	Irk before Filtering.	Irk after Polarite.	Medlock before Filtering.	Medlock after Polarite.
Oxygen required for 15 minutes.....	1.76	.34	2.07	.52	2.1	.41
„ „ 3 hours.....	3.70	.62	5.40	.81	9.3	1.50
Free ammonia.....	.72	.12	1.44	.40	2.4	.30
Albuminoid ammonia.....	.36	.14	.72	.11	.51	.12

The effluents which have been produced at Salford have been characterised by a freedom from colour and odour, and when one considers the highly-coloured Salford sewage, the results of such an effluent cannot but be considered as highly satisfactory. After quoting Sir H. Roseoe and Mr. Fletcher upon the electrical effluents, it will only be fair to quote what Dr. Frankland says of this polarite process.

"The effect upon the dissolved organic matter in the subsidence tank is very remarkable, its amount being reduced to little more than one-tenth of that present in the original sewage."

"In its subsequent passage through the filter, the dissolved organic matter is still further reduced to nearly

one-sixteenth of that present in the original sewage. It is now in a state of purity greatly exceeding that prescribed by the standards of the Rivers Pollution Committee."

In my investigations I have considered as a standard for a good effluent that the free and albuminoid ammonia shall be low, that the quantity of oxygen required for the 15 minutes and three hours shall be small, and that the appearance of the effluent shall be bright and clear.

Comparative table of Salford sewage and effluents resulting after treatment by indicated processes. It must be clearly understood, however, that the various effluents are not the result of the treatment of the sample of sewage of which the analysis is given.

Whatever process may be adopted for the treatment of sewage, one important fact has to be considered, viz., the amount of the resultant "sludge." The following experiments were undertaken in 1883 in view of this important phase of the subject:—

Sulphate of alumina and lime have been tried with the following results:—

No. 1.—Sulphate of alumina was used in the proportion of 5 cwt. to 1,000,000 gallons of sewage; the weight of the precipitate dried at 212° F. was 1 ton 18 cwt.

No. 2.—6 cwt. of sulphate of alumina was used in the same amount of sewage; weight of dry precipitate was 1 ton 18 cwt. 1 qr.

No. 3.—7 cwt. of sulphate of alumina; weight of dry precipitate was 2 tons 3 cwt.

No. 4.—8 cwt. of sulphate of alumina; weight of dry precipitate was 2 tons 1 cwt.

The effluent water from No. 4 was very clear; there was a very marked difference between this and No. 1.

No. 5.—Freshly burnt lime was used in the proportion of 5 cwt. to 1,000,000 gallons of sewage; the weight of the dry precipitate was 2 tons 13 cwt.

No. 6.—6 cwt. of lime; weight of dry precipitate was 2 tons 14 cwt.

No. 7.—7 cwt. of lime; weight of dry precipitate was 2 tons 15 cwt. 3 qrs.

No. 8.—8 cwt. of lime to 1,000,000 gallons of sewage, gave a precipitate weighing 2 tons 17 cwt. 2 qrs.

The effluent water from the lime treatment had a very noxious odour, and was not so clear as that from the sulphate of alumina. The weight of the wet precipitate I should calculate at about 6 tons to 1,000,000 gallons.

In the following experiments the sewage was much more foul than the previous sample. This sample was quite black. In consequence I found that very small quantities of lime and sulphate of alumina had very little effect in producing a good effluent water.

No. 1.—A quantity of lime was used equal to 2 tons to 1,000,000 gallons; in five or six hours the precipitate had subsided; the effluent water was quite clear.

The weight of the precipitate dried at 212° F. was 3 tons 8 cwt. 2 qrs.

The effluent water contained in 100,000 parts:—Ammonia, 1.2; albuminoid ammonia, .1; total solid matter, 125.

No. 2.—A quantity of lime was added to equal 1 ton per 1,000,000 gallons; also 5 cwt. of sulphate of alumina. Precipitate weighed 3 tons 9 cwt. 2 qrs. The effluent water contained in 100,000: Ammonia, .80; albuminoid ammonia, .17; total solids, .63.

No. 3.—Sulphate of alumina was added 12 cwt. to the 1,000,000 gallons. In a few hours a clear effluent water was obtained. The weight of the precipitate dried at 212° F. was 2 tons 4 cwt. 3 qrs. Effluent water in 100,000 parts: Ammonia, .70; albuminoid ammonia, .05; total solids, .47. The effluent water, even after many days standing in the sunshine, did not give forth any bad odours; it was comparatively speaking odourless. I cannot say so much for the effluent water from the lime treatment: there was a very disagreeable smell even after some days standing.

Results of experiments showing the difference in weight of dried sludge by the lime and the ferozone processes, August 6th, 1889:—

## DISCUSSION.

MR. GEORGE E. DAVIS writes:—"I am sorry that I am not able to be present at the adjourned discussion on Mr. Bell's paper, as I wished to say that he has been too hard upon the paper-makers. The paper manufacturers have been nearly the only people on the river who have seriously done anything to prevent their waste liquids from entering the water courses. In juxtaposition to them, let us place the bleachers: What have they done to prevent river pollution from their waste soda-ash liquor, from their lime-stews, and from their partly spent 'chemick'? Why do they not follow in the footsteps of their brethren, the paper-makers? In most cases the prevention of river pollution may be made a source of much private profit combined with public advantage, but the work must be done properly.

"The process of river purification must undoubtedly commence by prohibition of the entrance into watercourses, of solid matters in suspension in water. This by and bye will be recognised as *sine qua non*; but curiously enough section 20 of the Rivers Pollution Prevention Act of 1876 distinctly states that 'solid matter' shall not include particles of matter in suspension in water," so that by inference it is competent to put any quantity of solid matter into a river, provided it be in suspension in water. If any polluter, however, elects to do this, he will find that the Act of 1876 will not protect him, at common law, if it can be proved that he injures his neighbour lower down. The Act of 1876 is a dead letter, and a writ of the High Court is a 'premunire' to offenders who seek its aid.

"I am very pleased to find that Mr. Bell has emphasised the remarks, made in our book on 'The Irwell and its Tributaries,' respecting the Rivers Irk and Medlock. It is a disgrace to a city like Manchester to have two such open sewers flowing through such populous districts, but it is pleasing to know that the requirements of the Manchester Ship Canal will force a speedy cure for this."

MR. G. SISSON (Messrs. Peter Spence and Sons) said he had recently made a great many analyses of sewage and experiments on sewage purification dealing with large quantities, and consequently being able to obtain good average samples. He thought that it would be interesting to lay before the Society a few results on that more or less neglected portion of the analyses not mentioned in Mr. Carter Bell's otherwise exhaustive paper read at the last meeting, namely, the gases held in solution in fresh sewage and in the same sewage after keeping, with and without treatment by chemicals or otherwise, especially as regards the oxygen gas contained in solution, as this had a very important bearing upon any secondary or putrefactive changes taking place in the purified effluent from the sewage.

The following figures were obtained during the treatment of the Salford and Pendleton sewage by the aluminio-ferrie process:—

Fresh untreated sewage contained—

	Cc. per Litre.
Carbonic acid gas.....	18
Nitrogen.....	12
Oxygen.....	6

Some of the same sewage, after standing 24 hours *without any treatment*, contained—

	Cc.
Carbonic acid gas.....	21
Nitrogen.....	13
Oxygen.....	Nil.

The oxygen being completely absorbed by the organic matter.

After treatment of fresh sewage by the aluminio-ferrie process, samples of the continuous effluent were taken, and

kept in full glass-stoppered bottles from 16th October to 5th November last.

On 5th November these samples contained 5·5 cc. oxygen per litre.

Some of the same samples, kept as before, from 16th October to 1st December, contained 5 cc. oxygen per litre.

That is, whereas the untreated sewage lost all its free oxygen in 24 hours, the treated sewage, after being kept for six weeks, still contained five-sixths of its free oxygen.

This showed the importance of treating the sewage as soon as possible, in order to remove the organic matter before it had time to take up the oxygen. No noxious putrefaction can take place so long as any free oxygen remains dissolved in the effluent. It showed also the inadvisability of introducing any deoxidising materials, such as ferrous salts, sulphides, &c., which would absorb the free oxygen of the sewage, the oxygen so lost having to be replaced by filtration through oxidising materials, or by the addition of substances such as bleaching powder, manganates, &c. It was found that by treating fresh sewage with some precipitating substance which does not absorb oxygen, such as an aluminous compound, and allowing the precipitated matter to settle either continuously or intermittently, that the amount of dissolved oxygen in the effluent water is more than sufficient to oxidise the small amount of organic matter remaining in solution, the amount of oxygen absorbed by such organic matter being estimated by Tidy and Frankland's acid permanganate method in the usual manner, and this compared with the dissolved oxygen. To demonstrate this in a visible and practical way, samples of effluent were taken from some millions of gallons of sewage, treated as mentioned, kept in full glass-stoppered bottles from 16th October to 1st December, when an ordinary aquarium globe was filled up with a portion, in which were immediately placed some gold fish, where they have lived happily until the present time. The determinations of gas were made by boiling 1 litre of the sewage or effluent, kept boiling for not less than three-quarters of an hour, the gases given off being conducted into a graduated mercurial tube, brought to uniform temperature and pressure, the carbonic acid gas absorbed by the introduction of a small quantity of strong caustic potash solution, the oxygen absorbed by then introducing pyrogallin, the residual gas being taken as nitrogen. Dr. Dupré, in his report to the Medical Department of the Local Government Board, 1884, says: "A water which does not diminish in its degree of aeration during a given period of time, may or may not contain organic matter, but presumably does not contain living organisms. Such organic matter, therefore, as it may be found to contain by chemical analysis (permanganate or otherwise) need not be considered as dangerous impurity."

MR. R. F. CARPENTER asked if Mr. Sisson in his experiments had raised the effluent to anything like summer temperatures?

MR. SISSON: The temperature was raised to 65° F.

DR. G. H. BAILEY: Mr. Bell seemed to be satisfied so long as the effluent appeared clear. Had Mr. Bell made any determinations on microscopical examinations of the effluent after long exposure to the atmosphere.

MR. H. L. TERRY had frequently analysed the Medlock in Holme and found that the contamination was due to manufacturing refuse rather than to sewage. The total soluble solids varied from 30 to 80 grains per gallon, a large proportion of which was organic matter. This organic matter and the general greasy state of the solids in suspension was the great drawback to the adoption of the water for steam raising or other purposes in factories. He thought that the chemicals in the river neutralised the sewage, as the smell of the river in his district was rarely objectionable.

MR. CARTER BELL, in reply to Dr. Bailey, said he had taken determinations of the effluent, and had also made microscopical examinations, and when he found that the

albuminoid ammonia was in the second place of decimals, then he came to the conclusion that it must be a good effluent, especially if it was clear at the same time. They had not to seek impossibilities in these matters, all that was necessary was an effluent clear enough to turn into the Ship Canal. Alluding to Mr. Terry's remarks, he was of opinion that the Medlock was nothing more than an open sewer, and on many days was worse than the Salford sewage.

## ESTIMATION OF AVAILABLE SODA IN COMMERCIAL CAUSTIC SODA.

BY JOHN WATSON.

As it has been my daily work for the past three years to conduct and supervise the testing in the caustic soda department of the Newcastle Chemical Works (which works now, I believe, produce more caustic soda than any other in the trade), I naturally feel much interested in Dr. Lunge's remarks on the estimation of available soda in commercial caustic soda.

I read the paper by Messrs. Cross and Bevan when published; but was previously acquainted with the fact that the alumina (as well as the soda) of sodium aluminate acts as a base when methyl orange is used as indicator, on titration. Whilst agreeing with the main contention of Cross and Bevan, in their paper on "The economy of pure caustic soda" (this Journal, 1889, 252) I felt at the time that these authors exaggerated the real error caused by the use of methyl orange as indicator for titrating ordinary samples of caustic soda. They mention one case where a sample contained three per cent. of alumina; now this is most exceptional for white caustic, many samples of caustic "bottoms" containing no more alumina.

From a great number of full analyses of white caustic, made in the past three years, I give the following tabulated result:—

Newcastle Chemical Company's Caustic Soda. (Average of 21 analyses.)		Other Makers' Caustic Soda. (Average of 17 analyses.)	
$\text{Na}_2\text{Al}_2\text{O}_4 = \text{Al}_2\text{O}_3$		$\text{Na}_2\text{Al}_2\text{O}_4 = \text{Al}_2\text{O}_3$	
	Per Cent.		Per Cent.
·07	·04	·17	·10

In one exceptional case we had a sample of white caustic made by a Lancashire firm which contained aluminate equal to 1·73 alumina per cent.; but this I have not included in the above average.

It is obvious, therefore, that in most cases the alkali in white caustic soda may safely be titrated in the cold (or just warm) with methyl orange. I tried the method with phenolphthalein, as used by Cross and Bevan, shortly after reading their paper, and with our 77 per cent. caustic, got practically the same result as by the test made with methyl orange in the ordinary way; but I considered the boiling, subsequent cooling and back-titration too complicated, at least in our case.

With caustic "bottoms," methyl orange should not of course be used as indicator. Over three years ago I tried experiments on this subject, the result of which was that we adopted the following method: after dissolving a weighed portion of the bottoms in boiling water, filtering from the insoluble residue, and washing thoroughly, the filtrate was boiled, litmus added and the solution titrated in the way usual when this indicator is used.

## Estimation of Available, or Soluble, Soda in Alkali Waste.

There is one point in this portion of Professor Lunge's interesting paper to which I feel I must take exception.

The Professor describes briefly the method, used at some Lancashire works, communicated to him by Dr. Hurter.

This method, I gather, is practically the same as has been in use for over 10 years (to my knowledge) in the laboratory of the Newcastle Chemical Works. In the brief description, on the proof sheet which we possess, there is, I think, a misprint: "boiling the solution to decompose the calcium carbonate" should read, I take it, "boiling the solution to decompose the calcium bicarbonate."

The chief point, however, that I wish to draw attention to is that, according to Dr. Lunge and Mr. Zalscecki, less than one hour's treatment with gaseous carbon dioxide is not sufficient. Possibly they have worked on a very much larger quantity of waste than we do. With a view to some member, or Dr. Lunge himself, helping to clear up this point, I will explain our *modus operandi*:—

Twenty grms. of waste are treated with about 150 to 200 cc. warm distilled water; after stirring and allowing to stand for about an hour, the clear liquid is decanted, and a stream of carbon dioxide passed through it, for three to five minutes.

The effect of this may be seen if watched: First, the carbon dioxide causes a milkiness, owing to precipitation of calcium carbonate, then the solution clears as this calcium carbonate is dissolved as bicarbonate, in the excess of carbonic acid, sulphuretted hydrogen is then evolved, and at this point we consider that enough  $\text{CO}_2$  has been passed through to convert lime existing as hydrate, or soluble carbonate, into bicarbonate.

We then evaporate to at least half the original bulk, generally lower, filter off, and wash the calcium carbonate, titrating the alkali in the filtrate with a weak standard acid, using methyl-orange as indicator. As our average for the past year has only been ·025 soluble soda per cent., there cannot be much, if any, alkaline lime present in the filtrate. That lime is present in this filtrate, I am aware; but it is, I believe, in a neutral state combined mostly as calcium sulphate. My reasons for this opinion are, that tank waste in the moist state contains about 1 per cent. of calcium sulphate. (An average of five analyses gave 1·09  $\text{CaSO}_4$  per cent.). Part of this will no doubt be dissolved on treating the waste for available soda, and I have tried an experiment which shows that an aqueous solution of calcium sulphate is not decomposed by a stream of carbon dioxide passed through it for 15 minutes. Calcium sulphate would, therefore, find its way into the filtrate, but, being neutral, would not effect the final titration. Since reading this portion of the paper, on Tuesday, I have had very little time to try experiments on this point; but my assistant, Mr. T. S. Laidler, has kindly made two determinations of the lime and the sulphuric acid in the filtrate from the aqueous extracts from two samples of waste treated as

above, and to-day I made one determination of each in a different sample. The results were:—

	$\text{SO}_3 = \text{CaSO}_4$		$\text{CaO} = \text{CaSO}_4$	
				Per Cent.
I.	·46	·78	·50	1·21
II.	·16	·27	·65	1·57
III.	·33	·56	·49	1·19
Average .....	·32	·54	·55	1·32

These results, it will be seen, do show an excess of lime over and above that required to combine with the  $\text{SO}_3$  to form  $\text{CaSO}_4$ , and so far this favours Dr. Lunge's recommendation; but we cannot base much reliance on these few experiments, and tank-waste has so many constituents that some other neutral lime compound may possibly be present.

This morning Mr. Laidler tried two portions of different samples of waste for soluble soda by our ordinary treatment, and at my suggestion he tried duplicate portions of these, passing a stream of  $\text{CO}_2$  through for a little over an hour. The results were as follow:—

#### SOLUBLE SODA IN TANK WASTE.

Sample.	A.	B.
	Per Cent.	Per Cent.
After passing stream of $\text{CO}_2$ for 3 to 5 minutes	·034	·034
After passing stream of $\text{CO}_2$ for 70 minutes ..	·030	·030

The results were, therefore, practically the same in both cases.

From the fact, stated before, that our average soluble soda in tank waste for the past year has only been ·025 per cent., my opinion is that even with 3 to 5 minutes "gassing" with carbonic acid, and with treatment as described, alkaline lime will be absent, or practically absent, in the filtrate when titrated.

#### EGYPTIAN SALT.

BY H. DROOP RICHMOND AND HUSSEIN OFF, KHEDIVIAL LABORATORY, CAIRO.

THE salt supply of Egypt is almost exclusively obtained from the beds of salt left by the evaporation of the water on the northern coast, and on the borders of the inland lakes of the delta: the salt district stretches from Mex, near Alexandria, to beyond Damietta, including the salt lakes Bourlos, Edko, &c., and going as far inland as Damahour. The collection and sale of this salt is a Government monopoly, and there is a large tax on this industry. As salt is found in considerable quantities on the mountains inland, there are inducements to the sale of the contraband article, and consequently it frequently devolves on the Khedivial laboratory to give an opinion as to whether specified samples are contraband or not. In some cases the quantity of impurities is so great in the contraband salts that the task is easy, but it was considered desirable to examine a large number of salts of the Government to see if the composition was sufficiently constant to enable us to lay down a standard. With this view, we obtained samples from each of the different centres of collection and from the different depôts of Cairo.

As we frequently have a considerable number of samples at one time, we have adopted a method which, while not pretending to be of absolute accuracy, gives a sufficiently exact analysis in a short time; it differs but slightly from the ordinary methods of analysis, but as the differences

economise time, we give it in full; 10 grms. of the salt are weighed out, dissolved in a small quantity of water, and evaporated to dryness with hydrochloric acid on the water-bath; the residue is taken up with dilute hydrochloric acid, and filtered into a 250 cc. flask, the residue being weighed as silica. Of the filtrate 100 cc. (= 4 grms. salt) is precipitated by means of a concentrated solution of barium chloride added drop by drop to the boiling solution, and the precipitate allowed to stand, when practicable, till next day. Another 100 cc. is made alkaline with ammonia, and without filtering off the precipitate of oxide of iron, &c. ammonium oxalate is added, drop by drop, to the boiling solution, and the precipitate of calcium oxalate and oxide of iron, &c. is filtered off; the filtrate and the first two washings are collected in a beaker, and sodium phosphate added to precipitate the magnesia, as usual, and this is allowed to stand till next day. In this way the bulk of the solution from which the magnesia is precipitated does not much exceed 150 cc., and does not contain too large quantities of ammonium salts; and as the amount of magnesia is small, the loss from incomplete washing is quite negligible. The precipitate of calcium oxalate, &c. is thoroughly washed, the washings being collected apart and thrown away, and is burnt at a low temperature and weighed as calcium carbonate and oxide of iron; it is then dissolved in a small quantity of hydrochloric acid, and the iron precipitated with ammonia and weighed, this quantity being subtracted from the total weight. Another portion of about 2 grms. of salt is carefully heated in a covered crucible over a small flame, to estimate the moisture.

In the calculation of the results we have departed from the usual custom of combining all the sulphuric acid with lime as calcium sulphate, but have preferred to express it as a double sulphate of soda and lime,  $\text{CaNa}_2(\text{SO}_4)_2$ ; our reasons for this are (1) we have observed several times that salts containing practically no magnesia, and lime in proportion about equal to the sulphuric acid present, are hygroscopic, a thing which could not be explained, unless we supposed that some of the calcium was combined with chlorine; (2) we prepared three samples of salt from the same liquor, one ( $\alpha$ ) by very slow crystallisation at the ordinary temperature, one ( $\beta$ ) at about  $35^\circ \text{C}$ ., and the third ( $\gamma$ ) as rapidly as possible at a boiling temperature; the results of the analysis of these samples are as follows:—

	Silica.	Oxide of Iron, &c.	Lime.	Magnesia.	Sulphuric Acid.	Moisture.
$\alpha$	·08	·03	·76	·05	·97	1·50
$\beta$	·02	·02	·55	·18	·84	5·26
$\gamma$	·01	·03	·50	·46	·45	3·42

As it may be safely assumed that the moisture, silica, and oxide of iron are accidental impurities, and liable to vary from extraneous circumstances, we have calculated the percentages on the salt as free from them, as follows:—

	$\alpha$	$\beta$	$\gamma$
Calcium sodium sulphate .....	1·71	1·52	·80
Calcium chloride .....	·84	·55	·60
Magnesium chloride .....	·11	·45	1·13
Sodium chloride .....	97·34	97·48	97·38
	100·00	100·00	100·00

It is thus seen that the higher the temperature at which the salt was prepared, the less is the amount of sulphuric acid, and were this all as calcium sulphate, it would be anomalous. We may add that each of the samples consisted of a considerable amount of salt, care being taken that approximately the same amount of salt was deposited in each case, and that the whole amount deposited

was mixed before analysis. So far we have not much evidence to prove that the sulphuric acid is combined as  $\text{CaNa}_2(\text{SO}_4)_2$ , all the facts indicating only that the sulphuric acid is not as calcium sulphate, but we have preferred to state our results as  $\text{CaNa}_2(\text{SO}_4)_2$ , as this salt is found deposited in the places where salt liquors are evaporated.

In the sample  $\gamma$  the proportion of sulphuric acid to sodium chloride is the same as in the liquor, while in  $\alpha$  it is more than twice as great.

The analyses of the salts are as follows, they are calculated as the salts present in 100 parts free from moisture, &c. :—

	100·00	100·00	100·00	100·00

From an examination of these results it is seen that the variations in the salts are too great to lay down a standard of purity. The moisture, as a matter of course, is of no use whatever in judging of the purity; the silica and oxide of iron, &c. are due to sand and dirt which have got mixed with the salt, and cannot be employed as indications, while the variations in the various salts are too great to give any reliable standard. The sulphate of lime and soda varies from ·14 to 1·65, the magnesium sulphate from 0 to ·80, the calcium chloride from 0 to ·99, and the magnesium chloride from ·09 to 1·39; nor do these different compounds occur in any fixed ratio.

We are therefore forced to the conclusion that the salt of the Egyptian Government has not a composition sufficiently constant to allow of standards being laid down.

### DISCUSSION.

Dr. BEDSON commented on the author's practice of stating the sulphuric acid present in the samples of salt as double calcium sodium sulphate, for the existence of which he did not consider there was sufficient evidence.

The CHAIRMAN pointed out that the plan of dissolving the salt with the aid of hydrochloric acid would cause any calcium present in the original sample as carbonate to be determined as chloride.

Dr. BEDSON afterwards exhibited and gave a demonstration of the working of Pettersson and Palmquist's portable apparatus for determining carbonic anhydride in the air, and also of an application, made by himself, of Lunge's volumeter to Dittmar's gas analysis apparatus.

## CONDENSATION OF CARBON PARTICLES IN SMOKE.

BY ROBERT IRVINE, F.C.S., F.R.S., ED.

IN the Society's Journal, May 31st, 1889, there is a short note (communicated by me) on the condensation of carbon particles in smoke; and as it represents the initial stage of the investigation, I make it the preface to the paper I am to communicate this evening on the same subject.

"In the manufacture of lamp black, hydrocarbons are burned in an atmosphere with a limited supply of oxygen; the resulting dense black smoke is conducted into large chambers, where, on account of the extremely sluggish draught, it is allowed to roll about until the particles, by attraction between themselves, gradually coalesce into masses, which after a lengthy period fall on the floor in the form of soot. This process is exceedingly slow, and the product obtained, from even an enormous condensing space, is comparatively very small. Consequently this manufacture is one carried on, on a limited scale, considering the magnitude of the plant required.

"I erected a glass structure 5 ft. x 4 ft. x 4 ft., in which were fixed two malleable iron plates, provided with a great number of points—these facing each other, the plates being separated by a distance of from two to three feet, and all the conducting surfaces, except these points, being carefully insulated with shellac varnish. This chamber was filled with smoke produced by burning pitch oil, which retained its opacity for at least two hours; so much so that on then looking through the chamber, a bright light placed on the other side was totally obscured by the vapour. The chamber was now refilled with smoke, and the whole atmosphere therein was to a greater or less degree electrified by coupling the conductors, which were connected to the plates with a small dynamo. The effect immediately produced was exceedingly striking, the minute particles of carbon at once separated from the opaque smoke, and were attracted to, or driven from, the points of the plates, congregating together in a most extraordinary manner; and in the space of two or three minutes the atmosphere in the glass chamber was almost entirely cleared of smoke. The prohibitory cost of electricity has however prevented the application of this process on a large scale, for the present at least."

This led me to infer that the condensation of the minute particles of carbon in smoke into concrete masses, could be effected by simpler and cheaper means. I carried out a series of experiments by which smoke was rapidly agitated by mechanical means. The results were practically the same as that obtained by electric disturbance.

Before proceeding to explain in detail these experiments, I wish to direct your attention to some of the properties of the products obtained when fuel is burned, more especially that known as coal.

When a microscopic slide is passed quickly over a smoky flame, a very thin semi-transparent film is left on the glass, which, when examined under a powerful microscope, presents the appearance of numerous particles of amorphous carbon, in a very finely-divided condition, each particle surrounded by an areola, or coating of oily matter.

MICROSCOPIC VIEW OF SMOKE PARTICLES SHOWING "AREOLA" OF HYDROCARBONS SURROUNDING THEM.

Here we have an explanation of two things. First, why a black fog may be and will remain persistently a fog while rain is falling. Each particle of carbon being, so to speak, surrounded by a waterproof coating and hence repelling moisture. Second, when the particles composing such a smoke fog are agitated, either by currents caused by changes of temperature, or by a vertical down-draught of air, this oleaginous coating causes the finely divided carbon particles to cohere, forming masses which the air cannot long support in suspension, and their condensation into greasy black smuts ensues, often with startling rapidity, and the fog clears.

If commercial lamp-black, or soot, which is the product of imperfectly burnt coal, is strongly heated, a large amount of empyreumatic matter is given off, which condenses on cooling into a brown greasy mass, consisting of crysene, pyrene, capnomar, &c., which causes ordinary lamp-black to cohere like damp snow when pressed, whilst after calcination (during which it has been deprived of the oily or greasy matter) it loses this property.

If we examine the smoke from a newly-made (or mended) fire, we find at first only light blue and yellow-brown coloured vapours given off (consisting principally of the solid and liquid hydrocarbons before referred to), these passing into the atmosphere, with which, if I may use the term, they "emulsify." This first stage is followed by the combustion of these products, which, as the coal becomes heated, are resolved into gases, which burn with a smoky flame. It is at this stage, owing to the imperfect combustion of these gases, that we have finely-divided particles of carbon formed, and the black smoke so produced is added to the grease-laden air of the first stage, and so long as the atmosphere into which these products are poured remains cold, damp, and still, what is known as a black or brown fog results.

In the last or perfect combustion stage, after all the volatile or bituminous matter has been driven off as gas and burned (represented by a red glowing smokeless mass of burning coke), we have nothing but carbonic acid and

water and some sulphurous compounds given off, which also pass into the air, but black fog cannot result from such products.

Taking the total products from a coal fire, consisting of permanent gases, carbon, greasy hydrocarbons, and water all together, the percentage amount of the carbon is very small; yet so great is its power of obstructing the light, that the amount present in the blackest fogs of our large towns is represented by the insignificant quantity of blacks or smuts which fall to the earth when the fog clears. This is estimated at 3 per cent. of the whole smoke.

We are aware that dense fogs disappear in many cases without apparent atmospheric changes or wind storms to drive away the smoke. This may be as already stated due to electrical disturbances or convection air currents, or to sudden rise of temperature in the atmosphere in which the smoke matter is suspended. In any and all cases however the effect is the same, viz., the agglomeration of the minute carbon particles into masses too heavy for the atmosphere to retain them in suspension; this agglomeration being due to the presence of hydrocarbons, which we have found to accompany or clothe each carbon atom in the smoke, and which causes it to deposit upon and defile buildings, trees, flowers, and other objects of beauty in and around our cities.

In a smoky town, when a breeze prevails, the smoke, in its horizontal passage through the air, gradually parts with its greasy-coated carbon to anything which impedes its progress, so that only a few miles away it loses its dolorous aspect, and assumes the soft dreamy haze so dear to the soul of the painter, but which, after all, is only an air emulsion of finely attenuated particles of grease.

This smoke and fog question, from an economic point of view, presents interesting features. The Hon. Rollo Russell, in a lecture delivered under the auspices of the National Smoke Abatement Institution, states that 20,000 tons of coal are consumed per diem in London alone. We will therefore, taking the solid carbon produced at only 3 per cent. of the coal burned, have 600 tons of smuts which will ultimately descend either on the city or in its immediate vicinity; and taking the volatile hydrocarbons at 10 per cent. of this amount of coal, we will, from the same source, have a daily pollution of the air to the extent of 2,000 tons of tar and other coal products.

As a chemical manufacturer, I sigh when I think of all this valuable material lost to us, either in the form of wasted heat producers or valuable chemical products in the shape of *aniline colours, ammonia, burning oils, paraffin wax, printing ink, &c.*, which, divorced from their natural channels, are floating about in the atmosphere, veiling the sweet sunlight and choking the lungs of both animal and vegetable life.

Of course, if we could overcome our sentimental desire for the cheerful though smoky blaze of the coal fire, and burn carbonised coal in our grates, these solid, liquid, and gaseous hydrocarbons would be saved and made profitable use of. In this case our chimneys might become ornaments to our houses, while the products of combustion would pass from thence as colourless gases.

But if we will insist on burning green coal, it is possible for us to do so and have the enjoyment of the blazing fire by constructing our house grates so that the green coal may be introduced at the bottom (as is now successfully accomplished in some forms of steam boiler furnaces) by which means the hydrocarbons given off from the heated coal are made to pass (with a regulated supply of air) up through the mass of incandescent coke which by this means would occupy the upper portion of the fire instead of the lower.

Many attempts have been made to introduce such a perfect combustion grate, but the usual condition of the atmosphere of our large towns proves that, as yet, either a scientifically constructed grate or one requiring extra care or involving extra attention on the part of the class who minister to the "smoke fiend," is far from general adoption.

In the coke and iron industries much has been done in the direction of utilising the gaseous and liquid products obtained from carbonised or partially coked coal, and

processes are in general use by which these instead of being wasted are now profitably made use of.

Efforts have been and are being made to introduce such carbonised coal (or coke) into use for household firing, and experience has proved its use to be twice as economical as ordinary coal, while it is impossible to produce smoke from it. But sentimental prejudices prevail over all such considerations as health, beauty, and what is more wonderful, money; nor will there be an end of the allied sins of waste and dirt which we so strongly cling to (and which in this connexion Russell in his pamphlet before referred to estimates, costs the city of London alone nearly six million of money sterling) until the law compels us to burn smokeless fuel either in the form of coke or gas.

Consequent upon the failure (from a money point of view) of the condensation of smoke particles by means of electric currents,\* as already explained I tried to obtain the same results as were then observed, by mechanical agitation of smoke, and I constructed a flue or chamber, partly horizontal and partly perpendicular, through which dense smoke, obtained by burning naphtha at the one end, was passed. In this chamber (which was a box about 20 ft. long and 1 ft. wide) was placed two sets of fanners, which were made to revolve near the point where the smoke entered, so that it might be driven about in the confined space, my idea being that under these circumstances the particles of oily-coated carbon would by their impact coalesce into large smuts and condense *in situ*.

On starting these experiments the smoke was allowed to pass through the apparatus undisturbed, and at the exit end of the flue a loose plug of white cotton wool was placed, so that the smoke had to pass through it without its exit being impeded. Two minutes after this plug was applied the amount of carbon condensed among the fibres had blackened it completely. A second plug replaced the first, which was again blackened in the same space of time. The fanners in the box were now set in motion, and what followed was observed through spy-holes in the box and flue, both behind and in front of where the fanners were at work. Before agitation there was the dense brown-black homogeneous cloud which the undisturbed smoke presented. After agitation we had an effect very similar to the breaking up of a mist scene among the hills; large veil-like black streaks taking fantastic shapes, and a continuous shower of large particles of carbon falling within the flue or chamber, a few feet from the point where the agitation of the smoke had taken place. At this stage another plug of white cotton wool was placed at the exit of the flue; after two minutes this presented only a grey appearance. A second and a third plug exposed for the same time to the process showed less and less colouration; whilst the plug applied at the end of eight minutes showed hardly any stain, showing that most of the carbon particles in the smoke had been condensed. The same end can be arrived at by employing air jets, so as to throw the smoke into rapid circulation. Of course the production of smoke was continuous during the experiments.

I have endeavoured to repeat this experiment with smoke free from empyreumatic products, but the difficulty is to get smoke in such a condition. When gas is used for the production of carbon in the shape of fine lamp-black, the smoke does not contain empyreumatic matter in any large proportion, but of course a large quantity of water-vapour accompanies the carbon particles; and as the heated gases and water become cold, each particle of carbon is surrounded by condensed water which acts in the same manner as already described, in causing the particles to coalesce into large masses.

We are all familiar with the result of introducing a cold body into a gas flame. For instance, if a white plate is placed over a gas jet we have at once deposition of carbon on the cold substance, which will not take place if the plate is heated to the same temperature as the flame. Advantage is taken of this fact in preparing a very fine variety of lamp-black. And in America where gas is given off in large quantity from the oil wells, a large trade has sprung up for the manufacture of what is called gas-black.

\* See this Journal, 1889, 377.

Simultaneously with my observations on this smoke cure question, Mr. Elliott of Queen Street, Cheapside, has introduced a means of smoke condensation, using an apparatus which virtually washes the smoke with water. I take the following descriptive account from a London paper.

"Mr. Elliott's apparatus virtually washes the smoke and converts it into innocuous steam, and turns the deleterious parts into lamp-black and other colouring material. It can be attached to any chimney or works without interfering with the ordinary operations. The process is simple. The smoke is drawn from the flue by a fan with a closed chamber in which a rapidly revolving paddle wheel acts like a washing machine. The black thick smoke which enters emerges as colourless steam, which leaves no smell on a cambric handkerchief. The transformation is complete."

Such appliances as Mr. Elliott's washer, and agitating smoke in chambers, may be adopted in factories, when the smoke may easily be deprived of its carbon and hydrocarbons (and even the carbonic and sulphurous acids may thus be profitably utilised). That is to say, there is now no difficulty in preventing the emission of coloured smoke from any factory chimney. Indeed, were the law to insist upon this being done, coal users would in the end find it to be to their profit. This remark applies equally to the largest factories and to the ordinary bakery. Perhaps then this is enough for the fulfilment of our duty as representing the Society of Chemical Industry. As yet we have been wholly unable to deal with the domestic smoke nuisance, which is almost as serious a problem to cope with as that of domestic drainage.

I need not further urge the immense importance of some means by which the enormous waste of valuable material may be prevented. Macanley, in a lecture delivered at Liverpool in February 1888, estimates the amount of coal wasted in this country per annum at 45,000,000 tons, costing 15,750,000*l.* at the pit mouth. We have seen in the experiments I made when smoke was agitated in a confined space, that it could be deprived of its carbon. The same thing can of course be effected by filtering the smoke through a porous material, or washing with water, but the adoption of any such plans as these would necessitate the entire reconstruction of our dwelling-houses, and is consequently not to be thought of, even if it could be practically carried out. The only real resource open to us seems to be in the use of a smokeless fuel in our domestic fire-grates, or a grate which will prove in every respect a successful smoke consumer where coal is used.

Did time permit, I would lay before you statistics as to the additional sum in money which would be saved, added to what at present is lost (in consuming bituminous coal) by adopting such a fuel or grate, and in addition an appalling catalogue of death caused to animals and plants, which would be avoided.

For information on these and other points I refer you to some excellent papers issued by the National Smoke Abatement Society, which deal not only with the evil but with the attempt to cure it.

#### NOTE ON SPONTANEOUS HEATING.

BY ROBERT R. TATLOCK, F.R.S.E., F.L.C., F.C.S.

THE tendency of many carbonaceous substances, both of an organised and structureless character, to combine with oxygen, under ordinary conditions, with evolution of heat, has been made the subject of much patient investigation, and a large mass of information relating thereto is now available. Inquiries in this direction, however, have had reference chiefly to the circumstances under which this phenomenon takes place, and to its prevention, with the view of obviating the disastrous consequences which it involves, when the temperature rises sufficiently high to char or to inflame goods of value. Much obscurity, however,

still hangs round the question of the nature of the products formed at the commencement and during the progress of the chemical action, and any work done with the object of throwing light on this point would probably be productive of valuable results. The observed slowness with which these substances combine with oxygen is more apparent than real, the time occupied being, not what is required for the action to take place, but rather what is necessary for the non-contiguous molecules to be brought into contact. There can be little doubt that if the ultimate molecules of these bodies were in contact with the necessary oxygen molecules in sufficient number, combination would be instantaneous, as in the case of metals in the pyrophoric condition.

Nor is it even known whether the comparatively small proportions of oxygen which take part in such action combine with the entire complex substance—an oil, for example—or only with some part of it, leaving the remainder intact. In some instances, however, the nature of the chemical changes has been very fully ascertained, as, for example, in the heating of barley in the process of malting, by which starch is converted into maltose and dextrin, with evolution of carbonic acid. The conditions which favour this low combustion are well known; they are, first, the presence of the carbonaceous body, which must always be one that would burn in the ordinary sense if heated to redness in air; second, the presence of air or oxygen; third, the presence of moisture; and fourth, at least a moderate temperature. All these being fulfilled, the mechanical condition of the substance is of the greatest consequence, as, if it is either in a porous or spongy state, or in a condition of fine division, the facility for heating is greatly increased, while a calm and still atmosphere aid very materially. The following examples illustrate the varied conditions under which this heating frequently takes place, particularly with regard to the nature of the material. A fire broke out, apparently spontaneously, in a workshop in Glasgow where "fire-lighters" were manufactured. These were prepared by mixing sawdust with melted rosin in certain proportions. On the following day some of the finished goods which had escaped injury were taken away for investigation. One pound weight of these were placed under a glass shade with a thermometer, and in less than an hour the substance burst into flame. An examination of the sawdust showed that it contained a large proportion of moisture when mixed with the resin, and farther experiments confirmed the view that this was the cause of the accident. Again, a quantity of weaver's "heddles," prepared, as usual, with boiled linseed oil, were sent from a factory in this town to Aberdeen. The railway truck which carried the goods took fire, to all appearance spontaneously, and there could be no doubt, from a careful scrutiny of the whole case, that the oil was the cause of the mishap, as the centre portion of the heddles, which alone was prepared with oil, was charred and carbonised, while the rest of the threads in the same bundle were intact. The same accident happened on two other occasions about the same time. Yet another instance:—A few hundred tons of dried fish guano were landed from a vessel at Glasgow harbour, and at once placed in bulk in a store with a stone floor. In a short time the material began to "heat" internally, in consequence of which it was opened out and spread more thinly over the floor by a gang of men, but while this was being done a large quantity of it suddenly took fire, and before the flames could be extinguished, a portion of the wooden beams of the ceiling was destroyed. The spontaneous heating and consequent conflagration of coal cargoes, especially those of large size, are too familiar to us to require any reference. If we assume that a cubic foot of coal weighs 75 lb., and a cubic foot of air 1·23 oz., and that for every three cubic feet of coal in hold, bunker, or store there is one cubic foot of air containing at least ·28 oz. of oxygen, we have conditions equivalent to 2 ewt. of coal, having probably a surface of 50 square feet, practically in contact with the ·28 oz. of oxygen, which, if it combined with carbon to form carbonic acid, would give out sufficient heat to raise the cubic foot of air from 60° F. to 5316° F., which is much higher than the temperature of any blast furnace. Of course in practice this temperature could not be attained by the combustion of the oxygen initially present, as the

heat would be partly communicated to the coal itself, and would partly escape with the warm air, for even if the atmosphere among the coal was dead still to begin with, the warmth imparted to it would cause it to expand, ascend, and pass away.

In order to determine satisfactorily whether it was the sulphur, the compressed or occluded gases, or the non-gaseous carbon compounds in coal that was responsible for spontaneous ignition, I took different kinds of coal—cannel and house coal—pulverised them finely, and after exposing them to the air for 24 hours to allow all contained gases to escape, dried them thoroughly at  $212^{\circ}$  F., and determined the percentage of sulphur existing as sulphuric acid in each. A weighed portion of each was then exposed to a temperature of  $350^{\circ}$  F. for  $1\frac{1}{2}$  hours, when it was observed that both samples had materially increased in weight, due, of course, to their having combined with oxygen. The sulphur in the state of sulphuric acid was then estimated in both, and found to be almost precisely the same as originally.

The following is a summary of the results:—

	Cannel Coal.	House Coal.
Increase of weight between $212^{\circ}$ and $350^{\circ}$ F. ....	2.00	1.20
Sulphur, as sulphuric acid, before heating. ....	0.07	0.04
Sulphur, as sulphuric acid, after heating. ....	0.19	0.10

It will be seen from these experiments that the increase of weight cannot be due to the oxidation of sulphur, as if it were there would have been a corresponding amount of sulphuric acid formed, which was not the case, and it could not arise from the oxidation of compressed or occluded gases, as even if these were not completely expelled by the minute pulverisation of the coal and exposure to steam heat, and had combined with oxygen, their products of combustion, being gaseous, would pass off at the high temperature, which would result in a *loss* rather than a *gain* in weight. It is this gain in weight which is the key to the whole question of the rationale of the process of spontaneous combustion in coal and other carbonaceous substances. The carbon or carbonaceous ingredients of the coal combine with oxygen, forming *fixed* substances, and so increase in weight by the amount of oxygen with which they have combined. Now, the amount of oxygen which entered into combination in these experiments was approximately 2 lb. to every 100 lb. of coal, and was capable, if utilised for the ordinary combustion of carbon, of giving off heat nearly equal to what is evolved when 1 lb. of coal is burned. These results, moreover, make it clear that whatever part the contained gases take in aiding the action at the commencement, they are not required to carry it on, as their combination to form new products could result only in loss of weight, and not gain.

It has often been stated, and with truth, that chemical analysis throws no light whatever on the liability of a coal to spontaneous combustion, but while this statement is correct for such analyses as are usually made, it by no means follows that a chemical examination of the coal carried out on proper lines might not be useful in determining its qualities in this respect. The analysis required for technical and commercial purposes is one showing the percentage of carbon, hydrogen, oxygen, nitrogen, sulphur, ash, and moisture, but the relative proportions of these are not and never were intended to have any reference to the safety or otherwise of a coal for shipment or storage, and it is only such tests as are made with that special object in view that can ever be of value for that purpose. But while the elementary composition of a coal gives us no information on this point, it is extremely probable that a knowledge of its proximate constituents or compounds would be of great service. These are the decomposition products of the woody matter from which the coal was formed, but unfortunately little or nothing is known of them

except that they differ widely in different coals, some of them being unstable in their nature and consequently liable to chemical changes with production of heat, while others are of a stable character, and therefore not prone to such change. The subject affords a wide and interesting field for investigation, both for the scientific and the technical chemist. It is not at all unlikely, however, that experiments on the small scale, such as those described, carried out upon the principal coals intended for shipment might indicate the degree of their liability to heat and ignite spontaneously. There are also other points worthy of attention, such as the amount of moisture which a coal retains after being air-dried. Many hold as much as 10 per cent. retained at  $60^{\circ}$  F. and expelled at  $212^{\circ}$  F., and it is reasonable to suppose that water may either take part in bringing about a chemical change, or that any portion of it which would be expelled by a moderate heat of say  $100^{\circ}$  F. to  $110^{\circ}$  F. would leave the coal to some extent in a spongy or porous condition, which would favour oxidation.

The spontaneous heating of oils in a finely divided state has been made a subject of observation among chemists and others for a very long period, and the conditions under which it takes place are too well known to require any reference. All that is necessary is that the oil should expose a large surface to the air, and if the latter is warm and still, the action commences with great ease and progresses with astonishing rapidity. Numerous and varied experiments have shown that some oils are far more prone to oxidation and heating than others. Among vegetable oils, linseed stands prominent in this respect, and of animal oils, seal shows the greatest tendency, while mineral oils not only show no disposition to heat, but when mixed in comparatively small proportions with heating oils, annul or neutralise the heating proclivities of the latter. Attempts based upon the results of spontaneous combustion experiments have been made to arrange vegetable and animal oils in the order of their liability to heat or to combine with oxygen, but their behaviour under experiment is far too fickle to allow of any but a very rough classification, admitting of certain oils being placed at or near the top of the list, others at the foot, and the remainder somewhere intermediate. It has been observed by Mr. R. T. Thomson, however, that those oils which are capable of combining with the largest proportion of iodine are precisely those which have the greatest affinity for, and combine with, the greatest amount of oxygen under favourable conditions; and there can be no doubt of the correctness of this view.

It has been, and still is, the result of painful experience, that many of the most destructive conflagrations owe their origin to the affinity of certain oils for oxygen, although there must be some instances in which this has been wrongly assigned as the cause. It is clear that any fire having its origin in a building such as a Turkey-red stove, where goods prepared with oil are suspended at a high temperature for a considerable length of time, would in all probability take place in one of three ways:—

*First.*—By the elimination of combustible vapour from the oil by the heat of the stove, producing an inflammable atmosphere, which would at once ignite on contact with a spark or flame.

*Second.*—By a spark escaping from a chink or crack in the heating flue of the stove (or brought into the apartment in some other way) coming in contact with the hot and dry goods.

*Third.*—By the extra heat—over and above that of the stove—generated by the oxidation of the oil; this would promote further action, developing more heat, and so the action would proceed, in an accelerating ratio, till the ignition point was reached, immediately before which a large quantity of inflammable vapour would be distilled off from the highly heated portions of the oil surface.

The first of these causes may be dismissed, as the amount of gas or vapour which could possibly be thrown off from the oiled goods would not be sufficient to form an explosive or inflammable mixture with the air, nor such as would ignite by contact of either spark or flame. The second could not and need not be made the subject of experiment,

as the effect of direct contact with fire is obvious. It is only the third of these probable causes, therefore, that could form the subject of direct inquiry, and for this reason, as well as because it seemed probable that the majority of disasters arose from this cause, I thought it desirable to institute a few experiments, with the object, not so much of throwing light upon this point, as of determining in what direction investigation might proceed.

In order to ascertain whether olive oil gives off an inflammable vapour such as would ignite on the application of a flame, or spontaneously at the temperature of a Turkey-red stove, say  $180^{\circ}\text{F.}$  to  $184^{\circ}\text{F.}$ , I prepared some grey cotton yarn by soaking it in a well-known brand of olive oil (Gioja), pressing out the excess until only 10 per cent. remained, and heated this in an Abel's flash-point apparatus for some hours at  $200^{\circ}\text{F.}$ , but no vapour was given off that would flash or ignite on the application of a light at any period of the trial. The same was tried on the "fatty acids" of olive oil, with the same negative results, which makes it certain that both olive oil and the fatty acid recovered from it are safe as far as this point goes. All the materials, both yarn and oil, were carefully weighed before and after in these trials, in order to ascertain whether there was any increase of weight due to oxidation of the oil at the high temperature, but the results were unsatisfactory, the weights fluctuating on account of the hygroscopic character of the cotton fibre, and the difficulty of getting accurate weighings without absorption of moisture from the air, which vitiated the results. Recourse was then had to heating the dry oil to a temperature of  $194^{\circ}\text{F.}$  alone, without any fibre, but merely spread in a thin film over the flat bottom of a platinum basin, with the result that in 24 hours there was a clear gain in weight of nearly 1 per cent., which steadily increased until a point was reached, at the end of 60 hours, at which it appeared to remain stationary, probably on account of some decomposition and evolution of vapour, thereby causing a loss in weight which would neutralise the gain in weight by oxidation. The oil was purified beforehand by removing from it the free oleic acid, which all olive oils in the market contain more or less. The fatty acids from oil were then tried in the same way, but instead of showing a gain, like the oil itself, they showed a loss nearly to the same extent, but this was no doubt due to a chemical change producing some volatile body which passed away, and that this more than counterbalanced the gain in weight by oxidation, which was really going on at the same time. The fatty acids of cotton-seed oil behaved in the same way, but those of linseed oil showed a gain of over 1 per cent. in 24 hours. Stearic acid, on the other hand, remained almost constant in weight after exposure for 50 hours.

Now, at first sight it may appear that as the fatty acids of olive, cotton, and other oils lose weight on being kept hot in a close place, the vapour or substance given off being inflammable, would give rise to an atmosphere that would "flash" on contact with a spark or flame, and that therefore these would be dangerous from that cause, but a little examination will show that this cannot be the case. Suppose an example in which a ton of fatty acids of olive oil was thinly spread over the surface of cotton goods in a stove  $60 \times 40 \times 30\text{ ft.}$  at  $182^{\circ}\text{F.}$ , and that the weight of volatile vapour given off in 24 hours was 1 per cent., the conditions would be 5,600 lb., or thereby, of air through which were diffused 22.4 lb. of combustible vapour or gas, which would be equal to 0.4 per cent. Such a mixture would be perfectly safe to carry a naked flame through, as it would neither take fire nor explode. About  $2\frac{1}{2}$  per cent. of the vapour would require to be present before a combustible or explosive mixture would be reached. The real danger lies in the accumulation of heat produced by the oxidation (involving increase of weight) of the oil. In the above example approximately 1 per cent. of oxygen would be taken up by the oily matter in 24 hours, which, if combined with carbon by combustion in the ordinary way, would give out heat sufficient to raise the whole air of the stove to a temperature of  $273^{\circ}\text{F.}$ ; but then the heat, as it was generated, if not removed, would at once become available for promoting further action, producing more heat, and so on until finally the ignition point was reached. But it

must not be forgotten that the heat generated would greatly exceed this, as every successive development of heat by the combination of the oxygen with the elements of the fatty acid would facilitate or accelerate oxidation, resulting in the production of more heat, and so on, till the firing point was reached.

## NOTES ON GALLOTANNIC AND GALLIC ACIDS.

BY J. NAPIER SPENCE.

I HAVE ventured to bring these notes before the Society, feeling the want of a test for gallotannic acid in presence of gallic acid.

I used a mixture of pure gallotannic and gallic acids as my reagents.

On addition of lead acetate to a solution of gallotannic and gallic acids, they are both precipitated as lead tannate and gallate, and according to Guyard, on addition of acetic acid the lead gallate is dissolved up, leaving a precipitate of lead tannate. I find, however, that the difference in solubility of lead tannate and gallate in acetic acid is so slight as to make it impossible to dissolve the one without the other.

Lead nitrate precipitates gallotannic acid and not gallic acid, but the lead tannate is soluble in gallic acid. Therefore, if you have a mixture of the two acids you get no precipitate unless the gallotannic acid is in excess, when the excess only is precipitated.

Alkaloids, gelatin, and starch precipitate gallotannic acid in presence of gallic acid only if the gallotannic acid is in large excess, as the precipitates are soluble in gallic acid. Ostermeyer, improving on Wagner's process, uses cinchonine and magenta as an indicator. Now, you get no reaction with cinchonine and gallotannic acid in presence of gallic acid, owing to the solubility of the precipitate of cinchonine and tannin in gallic acid. Magenta precipitates both gallotannic and gallic acids, so cannot be used as an indicator.

Ammonia cupric sulphate will precipitate gallotannic acid in presence of gallic acid and therefore makes a good test, as, by filtering off the cupric tannate you can precipitate the gallic acid from the filtrate.

Gerland's process uses a standard solution of tartar emetic in presence of ammonium chloride, which is supposed to prevent the precipitation of gallic acid. Now, I find that a solution of tartar emetic does not precipitate gallic acid unless the gallic acid solution is very strong, when it is not prevented by ammonium chloride.

Ammonia sulphate of nickel may be used as a test for gallotannic acid in presence of gallic acid, its action being similar to ammonio-cupric sulphate. As a colour test potassium cyanide is very delicate. With a solution of gallic acid it yields a bright crimson solution, and has no action on gallotannic acid if added to separate solutions of the respective acids, but if they are mixed it turns the crimson colour yellow, and by using a standard solution of gallic acid and potassium cyanide and matching the colour yielded by the sample with a standard solution of tannin, a fairly accurate result might be arrived at.

In the Chem. Soc. J. for August there appeared an abstract from the Compt. Rend. 110 (532-534) on the Volumetric Estimation of Tannin, by E. Guenez, which was as follows:—

"When a solution of tannin is added to a boiling solution of tartar emetic mixed with certain coal-tar colours, antimony tannate is precipitated and carries down the colouring matter in the form of a true 'lake.' After a sufficient quantity of the tannin has been added, the liquid above the precipitate becomes quite colourless. Gallic acid does not interfere. Green dyes only are suitable, and Poirrier's green 1JE gives very good results.

"Having found tartar emetic to precipitate gallic acid, I thought perhaps the colouring matter might prevent it, but tried it with the following results:—

"I made up the solutions as directed, following his instructions exactly.

"I took 10 cc. of the dye solution and boiled. I then ran in 1 cc. of the tannin solution when I got a curdy green precipitate.

"I went on boiling and adding 1 cc. as directed, but having reached 20 cc. I thought I would add 10 cc. as I could see a distinct colour in the liquid above the precipitate.

"At this stage the precipitate seemed to change in form (from a curdy mass to a slimy powder), and although I went on adding the tannin solution until I had reached 50 cc., I failed to get the liquid above the precipitate colourless, and on testing I found the solution to contain excess of tannin."

There seem to be two distinct forms of precipitates formed, and they, especially the second form, do not fall readily, as, according to Guenez, they should do.

By using a mixture of gallotannic and gallic acids I failed to get any precipitate, but, on adding the gallotannic acid in excess, the excess was precipitated.

I am indebted to the kindness of Dr. E. Kuecht, of Manchester, for the sample of Porrier's green, 4 J.E., which I used to test the above process.

## Journal and Patent\* Literature.

### I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

#### PATENTS.

*Means for Treating Spent Grains or other Analogous Material for the Separation of Liquid therefrom.* G. Thornley and T. Buxton, Burton-on-Trent. Eng. Pat. 16,891, October 25, 1889. 4d.

THE object of this invention is to provide means for separating liquid from spent grains or other material in a rapid, efficient, and economical manner. This is effected by a double process consisting in first pressing the grain and then in drying it, so that any desired quantity of the remaining moisture is driven off. The press suitable for the purpose is described in Eng. Pat. 13,259 of 1886. In drying, the grains are discharged from the press on to an endless web and are then carried through a chamber which is heated by a current of hot air, the extent of drying being regulated by the speed at which the web travels through the chamber. Millburn's drying machine is suitable for the purpose.—E. S.

*Improvements in Apparatus for the Evaporation of Fluids.* J. G. Chamberlain, Tipton, and G. E. Davis, Manchester. Eng. Pat. 17,938, November 11, 1889. 8d.

THIS patent relates to apparatus for the evaporation of liquid in a partial vacuum, a water-jet condenser being employed for producing the vacuum by the withdrawal and

simultaneous condensation of the resulting vapour. The evaporating liquid is heated by pipes traversed by steam fitted in the lower part of the vessel, the condensed water being collected and emitted through a steam-trap. The concentrated liquid overflows through a pipe from the evaporator into a tank placed sufficiently far below to admit of the vacuum being maintained through the luted descending pipe. Or the overflow may go into a second vessel, and may from that overflow into a third and so on, the operation being repeated as often as required with the aid of appliances for maintaining the desired flow of the liquor. Some variations are described.—B.

*Improvements relating to Apparatus for Evaporating, Concentrating, and Distilling Liquids.* R. A. Robertson and W. J. Mirkles, Glasgow. Eng. Pat. 20,784, December 27, 1889. 6d.

THE improvement consists in reversing the usual method of operating in multiple-effect apparatus, that is, the liquid to be operated upon is led first through that vessel of the series in which the temperature and pressure are the lowest, leaving at that where they are the highest. Steam is admitted at the end of the series, and flows in a direction contrary to that of the liquid. The concentrated liquid and products of condensation are discharged through pipes at a high temperature, and are therefore in a more liquid state, and the tendency to crystallisation is thereby reduced.

—E. S.

*Improvements in Apparatus for Distilling, Evaporating, or Concentrating Liquids or Solutions and the like, and for Condensing Exhaust Steam.* J. Wright, Westminster. Eng. Pat. 20,954, December 31, 1889. 8d.

THIS invention is to provide an apparatus for efficiently utilising the heat of steam for various operations by what is known as "multiple-effects," and can be adapted to the treatment of the liquors of soapworks, or sewage, or salt water, &c., and also for producing pure condensed water for wool-washing, dye-works, and other purposes. Four cylinders, preferably of a vertical form, are united with each other by suitable pipes and valves. Each cylinder has a chamber at the bottom from which inverted U-shaped tubes extend upwards; the cylinders constitute the evaporators, and the tubes the condensers. The upper part of the cylinder is provided with a steam strainer. Steam or vapour from the liquid in each cylinder passes from it into the chamber below the next cylinder, and into the inverted tubes, and so on through the whole series, until it arrives at the surface condenser, where its complete condensation takes place. The mode of construction is fully shown on the two sheets of drawings which accompany the specification.—E. S.

*Improvements in Filtering Machines.* J. A. Crocker, Brooklyn, U.S.A. Eng. Pat. 5446, April 10, 1890. 8d.

THE construction of this filtering apparatus includes a horizontal cylinder having hollow trunnions in the ends. The ends are partly double and have perforated pipes secured to the inner walls thereof reaching from one head to the other and communicating with the central trunnions by separate passages. The trunnions are fitted with two sets of circular valves connected by rods and sleeves in the centre of the cylinder, and so arranged that one passage may be open whilst another may be shut, and that both sets may be worked either simultaneously or separately, for the purpose of cleaning the pipes and passages, without stopping the apparatus. The claims are for the details of the arrangement, and the specification and two sheets of drawings should be consulted for further particulars.—B.

\* Any of these specifications may be obtained by post, by remitting the cost price, plus postage, to Mr. H. Reader Lack, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C. The amount of postage may be calculated as follows:—

If the price does not exceed 8d. ....	½d.
Above 8d., and not exceeding 1s. 6d. ....	1d.
" 1s. 6d., " " " 2s. 4d. ....	1½d.
" 2s. 4d., " " " 3s. 4d. ....	2d.

*Improvements in the Manufacture of Filtering Plates, in Apparatus for Testing the same, and in Filtering Apparatus.* W. L. Wise, London. From A. Egen, Schwerte, Westphalia, and E. Bassege, Berlin, Germany. Eng. Pat. 8614, June 4, 1890. 11d.

THE inventors produce filtering plates from a mixture of powdered coke or "cylinder coal" with tar and pitch, which is heated to plasticity and pressed into flat circular moulds. The mixture recommended consists of 100 parts by weight of tar, 40 parts of stone pitch, and 330 parts of sifted powdered coke or coal. In the middle of the moulded plate, across its whole thickness, is embedded a disc of coarse textile web or netting, not reaching quite to the circumference of the plate, and finished off all round with a rather thicker cord or strand than the remainder of the material. When so far completed, the plates are stacked in an iron vessel in a mixture of coal dust and sand all between and around them, and the whole is then exposed for about a fortnight to glowing heat in a furnace. After careful cooling the plates are removed and are found hard and porous, and are traversed in the interior by a number of small channels, communicating with a larger circular channel, where the textile material has been burned out. Two holes are then drilled into the edge of each plate at opposite diameters, reaching to the circular channel inside, whereby through communication is established. To construct a filter, a number of these plates are placed one above the other with spaces between, short tubes are inserted into the end holes, and all tubes on each side connected by a collecting pipe for the removal of the filtered liquor. The stack of plates is inserted in a cistern containing the liquor to be filtered, the purified water passing away through the collecting pipes. The deposit collects on the outer surface of the plates, whence it can be cleared off either by inverting the current of the pure liquid or by blowing steam through, or in any other approved manner. The specification describes fully the method of manufacturing the plates, the mode of, and apparatus for, testing them as to their soundness, and the construction of filters with the finished plates. There are four sheets of drawings and five claims.—B.

*Improvements in Distillation and in Apparatus therefor.* A. W. Ellis, London. Eng. Pat. 12,260, August 5, 1890. 11d.

IN his distilling apparatus the inventor makes use of a number of shallow vessels of rectangular section in plan. He places them one upon another, with suitable connexions and openings to allow of the liquid to descend and the vapour to rise through the system. The liquor in the vessels is heated by steam contained in coils laid just above the floor of each vessel, each coil consisting of a number of straight pipes slightly inclined in one direction, connected at their ends by cross-pipes, through one of which the steam enters whilst the condensed water leaves by the other and is conducted back to the boiler by gravity. Various modifications are indicated, as well as details and proportions of parts. There are three sheets of drawings and seven claims.—B.

*Improvements in Machinery for Effecting the Softening of Water and for the Clarification of the Softened Water.* C. E. Gittens, London. Eng. Pat. 12,533, August 11, 1890. 6d.

THE object of this invention is to effect, by automatic machinery, the softening of hard water as it is supplied to a tank or reservoir, in which the precipitate is allowed to subside. When space is an object, a subsidence filter of coke or other substance may be used to clarify the water from any precipitate in a more rapid manner. For this purpose the water, as it flows from the inlet, actuates a water-wheel which drives a pump (or an elevator with buckets) which can be adjusted to raise the proper proportion of the solution used for softening the water, and to deliver it into the tail-water running away from the wheel, so that it is intimately mixed with it.—E. S.

*Improvements in Apparatus for the Complete Evaporation of Solutions.* H. E. Hansen, Copenhagen, Denmark. Eng. Pat. 14,059, September 6, 1890. 6d.

THE object is to obtain an exceedingly rapid evaporation in vacuo of all kinds of solutions. The apparatus consists of a vacuum vessel inside which a double-walled funnel is caused to revolve slowly at some distance from the sides of the vessel. Both the inner and outer surfaces of the funnel are heated by steam admitted into the space between its walls. The rapidity with which evaporation takes place causes the product to be of such a light and porous nature that, e.g., in the case of malt extract, actual pulverisation is not needed, as merely grating it reduces it to a powder.—E. S.

*Improvements in Method and Apparatus for Producing Mineral Wool.* W. H. Kennedy, Etna, Penn., U.S.A. Eng. Pat. 14,846, September 19, 1890. 8d.

THE improvement consists in spreading out a regulated quantity of molten slag, which is contained in a cast-iron tank, preferably capable of holding about 15 gallons, in a fan-shaped stream, to the action of steam issuing from a series of round inclined perforations in the front of a steam chest, by which means the slag is reduced to "the greatest number and smallest possible fragments of fine fibre or wool, thereby increasing the quantity and improving the quality without increasing the power used." There are eight claims.—E. S.

## II.—FUEL, GAS, AND LIGHT.

*The Effect of Temperature on the Limits of Explosions of Combustible Mixtures of Gases.* J. Roszkowski. J. für Gasbeleuchtung, **33**, 491—497, 524—527, 535—537, and 553—558.

THIS is a lengthy account of experiments carried out under Dr. Bunte in the chemical laboratory of the technical school at Karlsruhe. It is prefaced by an account of the researches of Favre and Silbermann, Thomsen, and Berthelot on heats of combustion; of Bunsen and Deville on temperature of combustion and on dissociation; and of Bunsen, Berthelot, and Le Chatelier and Mallard on temperature of ignition and rapidity of explosion.

The author uses the term "limits of explosion" in the following sense: A combustible gas is capable of explosion not only when mixed with the exact quantity of oxygen required for its complete combustion, but also when the supply of oxygen is in excess of this. (This applies also to common air or mixtures of oxygen with other inert gases.) When the proportion of oxygen in the mixture is gradually increased, the explosion becomes weaker, and at last a point is reached at which the mixture can no longer be exploded. This is called the *lower limit of explosion*; it is that which corresponds to the smallest percentage of combustible gas. Similarly, if the proportion of oxygen present be gradually diminished, a point will be reached at which the mixture will be incapable, or only just capable, of explosion. The border-line separating the two is called the *upper limit of explosion*; it corresponds to the largest percentage of combustible gas. These limits have already been investigated by Bunsen (for electrolytic gas diluted with oxygen and carbon dioxide), Frankland (London coal gas), E. v. Meyer (hydrocarbons—upper limit only), and Lehmann and Wüllner. Wagner has shown that a mixture which cannot be exploded by a spark from a small induction coil may be exploded by a spark from a stronger coil. No experiments have hitherto been made on the effects of pressure and initial temperature. The author has investigated the latter point, which is of considerable

practical importance. In the cylinder of a gas engine, for example, there is a series of explosions occurring in which the combustible mixture is initially at a high temperature.

The experiments (over 1,000 in number) were made at the temperatures 15°, 100°, 200° and 300°. The combustible gases investigated were hydrogen, carbon monoxide, marsh gas and coal gas.

**I. Hydrogen.**—A. *Hydrogen mixed with oxygen.*—At the ordinary temperature (15°) the lower limit is a mixture containing 1 vol. of hydrogen to about 9·25 of oxygen: in other words, the mixture will still just explode when it contains 18·5 times as much oxygen as is required for the complete combustion of the hydrogen. The upper limit is 1 vol. of hydrogen to 0·1013 of oxygen at 15°, and 1 to 0·0654 at 300°. Thus rise of temperature extends the upper limit; it scarcely affects the lower limit. B. *Hydrogen and air.*—Here, again, rise of temperature causes no noticeable change in the lower limit (excess of air), whereas it extends the upper limit from 0·1147 at 15° to 0·0548 at 300°. (The limits are always expressed in terms of the volume of oxygen required per unit volume of the combustible gas, or else in percentage by volume of combustible gas in the mixture.) C. *Hydrogen and a mixture of oxygen and carbon dioxide.*—This mixture contained 21 parts of oxygen to 79 of carbon dioxide (always by volume). It might be regarded as common air in which the nitrogen was replaced by carbon dioxide. The experiments showed that generally the limits of explosion were even more restricted by dilution with carbon dioxide than by dilution with nitrogen. Up to 100°, however, the limits were somewhat extended (especially the upper one). Further rise of temperature restricted the range, so that a mixture which was explosive at 15° or 100°, would no longer explode at 200°, and one which would explode at 200° would not explode at 300°.

**II. Carbon Monoxide.**—A. *Carbon monoxide and oxygen.*—At 15° the maximum amount of oxygen that could be added was 5·41 vols. to 1 vol. of carbon monoxide, i.e., 10·8 times the theoretical amount. The minimum amount of oxygen necessary was 0·066 vol. These correspond to mixtures containing 15·6 and 93·8 per cent. of carbon monoxide respectively. The range increases from 0° to 100°, and from 100° to 200°, but from 200° to 300° it diminishes, the limiting values at the latter temperature being 3·140 and 0·086 vol. of oxygen, or 21·4 and 92·5 per cent. of carbon monoxide. B. *Carbon monoxide and air; and, C., carbon monoxide mixed with oxygen and carbon dioxide* (see I.—C.). The results in both cases were similar to those obtained when oxygen alone was used. The author repeatedly found that mixtures which could be exploded at the ordinary temperature would not explode if they had previously been heated to 300°. He attributes the restriction of the limits (especially the upper limit) at high temperatures to a gradual union of the combustible body with the oxygen at these temperatures. This is supported by the appearance of a bright blue aureole around the sparking wires, and also by actual analysis of mixtures before and after heating.

**III. Marsh Gas (Methane).**—A. *Marsh gas and oxygen.*—At 15° marsh gas requires at least 0·7517 of its volume to form an explosive mixture with oxygen. It can support an admixture of 14·7 vols. of oxygen, or about 7·3 times the amount required for its complete combustion according to the equation  $\text{CH}_4 + 2 \text{O}_2 = \text{CO}_2 + 2 \text{H}_2\text{O}$ . Rise of temperature scarcely affects the limits; this is true also for the next mixtures (B. and C.). B. *Marsh gas and air.*—The mixture must contain about twice as much oxygen (1·323 vol.) as when pure oxygen is used. It still explodes when it contains 3·29 vols. of oxygen or 15·65 vols. of air to 1 of marsh gas. C. *Marsh gas with the same mixture of carbon dioxide and oxygen.*—Admixture with carbon dioxide restricts the limits much more than admixture with nitrogen. They lie very near together, the extremes being mixtures containing 9·0 per cent. and 11·6 per cent. by volume of marsh gas. This nearly corresponds to the theoretical quantity required for combustion.

**IV. Coal-gas.**—The gas used was from the town supply of Karlsruhe.

The composition of the gas at the commencement and end of the experiments is shown in the following table:—

	Before Feb. 22, 1890.	After March 4, 1890.
Hydrogen.....	Vol. per Cent. 50·6	Vol. per Cent. 48·6
Marsh gas .....	31·8	33·6
Carbon monoxide .....	6·2	6·5
Hydrocarbons (ethylene, benzene, &c.) .....	5·3	5·3
Carbonic acid.....	1·9	2·1
Nitrogen (residue).....	1·2	2·8
	100·0	100·0*

\* In original.

A. *Coal-gas and oxygen.*—At 15° coal-gas requires at least 0·4358 of its volume of oxygen to form an explosive mixture. It can support admixture with 12·25 vols. of oxygen (the amount found by experiment to be necessary for complete combustion being almost exactly 1 vol.). These correspond to mixtures containing 69·6 and 7·5 per cent. respectively by volume. At 300° the upper limit is increased by 2·3 per cent., the lower only by 0·3 per cent. B. *Coal-gas and air.*—At 15° the lower limit is 13 vols. of air or 2·8 vols. of oxygen to 1 of coal-gas, the upper limit 0·71 vol. of oxygen. These correspond to mixtures containing 7·0 and 22·6 per cent. by volume of coal-gas. At 300° the upper limit is extended by 6 per cent.; the lower by 0·5 per cent. C. *Coal-gas with a mixture of oxygen and carbon dioxide.*—At 15° the limits are 7·9 and 25·1 per cent. by vol. of coal-gas. At 300° they are 9·4 and 18·0 respectively; so that rise of temperature narrows the range.

All the above experiments were made with moist gases. Similar results were obtained with dry gases, excepting that carbon monoxide (as already shown by Dixon and Clerk) did not in any case explode. The gases used were not always quite free from admixture with air, but in all cases they were as pure as could be expected, considering that they had to be stored in considerable quantity. The transition from explosive to non-explosive mixtures was not by any means abrupt; as the composition of the mixture was altered, the force of the explosion usually became less and less, until it passed into a slow combustion in the neighbourhood of the sparking-wires.

The original paper contains copious tables of results together with theoretical discussions and details of methods of preparation, analysis, and experiment.—D. E. J.

*The Petroleum Industry at the North-west German Exhibition, Bremen.* R. Kissling. Chem. Zeit. 14, 1117—1119.

THE chief industry carried on in the neighbourhood of Bremen is that of petroleum refining. The crude material is imported in tank-steamer chiefly from America, and is worked up by repeated distillations into three classes of products. Of the first, the most volatile portion is used for the preparation of "air-gas," the residue being employed for cleaning purposes, fat extraction, &c., and as a source of power in small engines. The second group consists of illuminating oils of various qualities, and the last of paraffin and machine greases.

Models of the plant employed, both in America for obtaining the crude product, and in Germany for refining it, together with samples of the spirits and oils in various stages of their manufacture, are exhibited, as are also different forms of apparatus for testing the products.—F. H. L.

*Egyptian Petroleum.* H. Kast and A. Kunkler. Dingl. Polyt. J. 278, 34—42.

PETROLEUM is found in Egypt at Gensah on the banks of the Red Sea, and has been described by Weil (Monit. Scient. 19, 295) and by Irvine (this Journal, 1887, 130 and 276).

The oil examined by the authors was dark brown, almost opaque, and when diluted with petroleum spirit had a green fluorescence. Its specific gravity at 17° was 0·9352. On cooling to -15° it became somewhat thicker, but no solid paraffin separated out. Its speed of flow measured in Engler's viscosimeter at 35° was 6 minutes 40 seconds. Treated with alcohol and water, the extracts had no action on litmus paper. The ash amounted to 0·12 per cent. and consisted of iron and lime. When distilled up to 280° the only gas evolved was sulphuretted hydrogen. The amount of hydrocarbons soluble in a mixture of concentrated and fuming sulphuric acid in the portion of the oil distilling up to 310° was found to be 24 per cent. The residue (76 per cent.), consisting of paraffins and naphthenes, was examined as to its refractive power, and gave figures closely agreeing with those obtained from Baku petroleum, which consists chiefly of the latter; the Egyptian oil, however, contained sulphur, even after the treatment with acid, hence the refractive indices cannot be taken as a proof that naphthenes form the largest part of the hydrocarbons.

From the following table of the boiling points, it will be seen that both mesitylene and pseudocumene are absent:—

—	Per Cent. by Volume.	Specific Gravity at 17°.
200	·0	·821
201—225	0·8	·817
225—250	13·7	·874
250—275	7·0	·892
275—300	29·6	·879
Residue	31·9	
	100·0	

During the distillation considerable decomposition occurred, which is probably the cause of the lower specific gravity of the last fraction.

The oil was examined as to its commercial value by distillation from a copper still, superheated steam being employed when the temperature reached 200°, as is done at Baku; it gave:—

—	Per Cent.	Specific Gravity at 17°.	Flash Point.	Consistency.
Burning oil, .....	11·3	·841	64	..
Intermediate ....	25·0	·880	95	..
Machine II. ....	16·7	·927	144	Liquid at -10°.
Machine I. ....	16·7	·949	195	Liquid at 0°.
Cylinder. ....	17·0	·955	173	Thick at 15°.
Coke and loss ....	13·3			
	100·0			

Tested for illuminating power in Elster's photometer, the burning oil gave a light of 9·8 German standard candles, the weight of oil burnt per hour being 31 grms. Exposed to air it rapidly developed an unpleasant smell.

The authors consider that Egyptian petroleum is not suitable for the manufacture of illuminating oils, but is an excellent material for the preparation of lubricating oils.

—F. H. L.

## PATENTS.

*Improvements in and connected with Furnaces for Burning Liquid Fuel.* C. A. Sahlström, London, J. C. Bromfield, Hove, and A. F. Hill, West Brighton. Eng. Pat. 14,338, September 11, 1889. 11d.

THE invention relates to various forms of furnaces which are heated by liquid fuel which is forced or blown in as fine spray by means of steam or air or both combined, and burnt with superheated steam and hot air so combined as to obtain the greatest possible heat. Drawings and descriptions are given of (1) a steam-boiler furnace; (2) of a cupola furnace; (3) a brass and copper smelting furnace; (4) a portable or movable retort furnace.—H. S. P.

*Improvements in Oil-Gas producing Apparatus.* J. Lawson, Bridlington Quay. Eng. Pat. 16,009, October 11, 1889. 6d.

THE oil is conveyed by gravity from a tank through a tube to the lower end of a spiral of hydraulic tubing placed in a furnace. Herein it is vaporised and conducted from the upper end of the coil to the condenser where the naphtha collects, and the gas passes onwards to the gasometer.—A. W.

*A New or Improved Artificial Fuel.* J. H. Wood, London. Eng. Pat. 17,480, November 4, 1889. 4d.

THE fuel is for use "in Portland cement works, and also in foundries for foundry work, in boilers and for domestic and other purposes." For Portland cement works the following mixture is said to be suitable, but may be varied:—90 per cent. of coke breeze or coke dust, 7·5 per cent. of pitch, 2 per cent. of "slurry, that is to say a plastic admixture of carbonate of lime, silica, and alumina," 0·375 per cent. of astatki or the semi-liquid residue of petroleum after it has been refined, 0·125 per cent. of soda, potash, or bicarbonate of soda. The coke dust and pitch are mixed separately and the slurry, astatki, and alkali also separately. The two mixtures are then fed into a chamber and heated by superheated steam, and stirred by suitable appliances. The combined mass is then cooled and pressed into blocks or bricks. For foundry purposes the slurry may be omitted, and the astatki increased and some slaked lime added. For domestic purposes a small proportion of coal-dust may be substituted for some of the coke-dust, and the proportion of pitch reduced.—H. S. P.

*Improvements in Apparatus for the Manufacture of Illuminating or Heating Gases.* W. Wood, Philadelphia, U.S.A. Eng. Pat. 19,572, December 5, 1889. 8d.

A CONTRIVANCE applicable, wholly or in part, to apparatus for generating water-gas, by which steam is superheated before being passed into the generator, and by which, if desired, oil may be introduced either into the generator or into the gases as they leave the generator. For details the specification and drawings must be consulted.—H. S. P.

*Improvements in Apparatus for Burning Hydrocarbon and other Oils.* G. Gerrard, London. Eng. Pat. 19,730, December 7, 1889. 8d.

THE lower end of a coil of tubing terminates in a jet which is turned upwards towards and is placed underneath the central axis of the coil, so that the latter is heated by the flame from the jet itself. The coil and jet are placed in a tube or casing which may be closed or have a regulated opening at the lower end, but which is open at the top. The oil is supplied to the upper end of the coil, either by gravity or by a pressure tank.—A. W.

*Improvements in Regenerative Gas Furnaces and Gas Producers.* F. Siemens, London. Eng. Pat. 20,983, December 13, 1889. 8d.

THIS is a claim for having a gas producer near the furnace chamber of a regenerative gas furnace, with means of supplying the producer with heated air from the regenerator and also with means of supplying it with the hot products of combustion from the furnace, or with cold air, in any desired proportions. The accompanying drawings illustrate

Fig. 1.

Fig. 2.

REGENERATIVE GAS FURNACE.

as determined by the opening of one or the other of two valves V. The hot air from the regenerator B flows partly by the passage F to the furnace port E, where it meets the gas from D, and the flame sweeps round from E to E'. Part of the hot air from B is caused by the steam jet K, to pass to the producer C at the one side, while at the other side a portion of the hot products of combustion is made to pass also into the producer by the steam jets K K'. By regulating these jets K K', any desired proportions of hot air and of the hot products of combustion can be supplied to the producer, or the passages thereto may be entirely closed by the valves U. Cold air, if required, is supplied by an auxiliary steam jet J. The reversing valve W is of the ordinary construction. A pipe leading from a blower is fixed to it, so that if desired an air blast may be employed, in which case it is not necessary to employ the steam jet K. Combinations such as the above may be made with regenerators of the reversible type or with those of the continuous current principle, and these are further illustrated in the specification.—A. W.

### III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

*On the Formation of Petroleum.* A. Veith. Chem. Zeit. 14, 1368.

ENGLER's researches have shown that petroleum is of animal origin. It is formed by the decomposition of marine animals, the nitrogenous organic matters being decomposed with evolution of ammonia, and the fats, under the influence of heat and pressure, into glycerol and fatty acids; the first is washed away and the latter are further decomposed with formation of hydrocarbons and water.

Engler considers the production of carbon dioxide and carbon monoxide, in the conversion of fish oil into petroleum, to be the result of a secondary reaction, as these bodies occur only in very small quantities in petroleum, and the less of these gases that are formed the more regularly is the reaction considered to proceed.

Engler's experiments can also be explained in another way. The conversion of fats into hydrocarbons may be brought about as follows:—The fat is first decomposed into glycerol and fatty acid. The glycerol is then converted under the influence of heat and pressure into acrolein, and by the elimination of water and condensation this is converted into benzene, while the fatty acids under the same conditions are converted into hydrocarbons and carbon dioxide. The carbon dioxide under the influence of dissociated hydrocarbons is reduced to carbon monoxide, and ultimately to volatile hydrocarbons.

The author thus considers that when gaseous hydrocarbons are found associated with petroleum, they are formed from carbon dioxide as above; when they are absent, he considers that the carbon dioxide has been absorbed by basic earths, with production of carbonates.—A. L. S.

*Improvements in and Relating to the Treatment of Wood, rendering the same highly Inflamable.* J. Gridley, Kingston. Eng. Pat. 13,767, September 2, 1890. 4d.

WOOD of any convenient shape and size is thoroughly dried by heat and placed in a boiling solution of resin in petroleum until it becomes impregnated with the same, after which it is taken out and subjected to a temperature of 400° F.—A. W.

*Action of Manures containing Thiocyanates (Sulphocyanides).* E. Mack and K. Silen. Tyroler landw. Blätter, 1890, 8, 198—200.

See under XV., page 1140.

## PATENTS.

*Improvements in Separating Tar and Ammonia from Gases, and in Apparatus therefor.* F. N. Mackay, Freshfield. Eng. Pat. 14,060, September 6, 1889. 8d.

THE object of the invention "is to economically cool blast-furnace and like gases, and remove tar and ammonia or other products therefrom."

The apparatus consists of a series of serpentine cooling pipes, of a tower where the gases are washed with water, a tower where they are washed with oil, and a "drying tower." The whole of this apparatus is jacketed, and the entering gases circulate through the jackets of each section of the apparatus before being brought into the washing and drying towers, and finally into the serpentine cooling pipe from whence the washed gases leave the apparatus. In this way the entering gases, while travelling through the jackets, are cooled by the returning gases. The gases, on entering, first pass through the jacketed space surrounding a series of cooling pipes, and thence into a main with branches leading to sets of three towers, each set consisting of a water-washing tower, an oil-washing tower, and a "drying tower." Following one of the branches, it is seen that the gases first pass through the jacket of the drying tower, then through the jacket of the oil-washing tower, and lastly through the jacket of the water-washing tower. From the jacket of this last tower the gases gain access at the bottom to the interior of the tower and pass up the tower, thence into the oil-washing tower, and next into the drying tower, and then into a main, from which the cooling pipes branch off.

The water-washing tower is divided into compartments by perforated plates alternately perforated in the centre and at the circumference, some of the compartments between the plates are filled with broken bricks, coke, or other suitable material, others are left empty, and are fitted with man-holes, whilst the bottom compartment is preferably filled with pieces of corrugated metal, bent wire, &c. A descending stream of water washes the gases as they ascend the tower, and the tar and ammonia-liquor are drawn off at the bottom. The gases enter the oil-washing tower at the top, and pass down the centre of the tower by a central pipe which reaches nearly to the bottom, and then ascend through an annular space between the central pipe and the jacket of the tower. This annular space is divided into compartments by perforated plates, on some of which are placed broken bricks or coke, and a stream of oil flows down the tower, through the plates, and over the material placed on them, and absorbs "various products still remaining in the gases." The gases then pass down the drying-tower, and any oil and water that is carried over drains off into the main, from whence the gases now pass to the cooling pipes.

Drawings of this apparatus and of a modified arrangement in which an ammonia refrigerator or other refrigerator is introduced, accompany the specification.—H. S. P.

*Improvements in Apparatus for Distilling Mineral Oils.* N. M. Henderson, Broxburn. Eng. Pat. 17,232, October 31, 1889. 8d.

THE "invention relates partly to the heavier mineral oils, such as those obtained in redistilling crude shale oil, and has for its object" the recovery from such oils of superior oils suitable for lubricating and other purposes.

The still used is a circular one, and is made in two parts—a hemispherical bottom of cast iron and an upper part of larger diameter of wrought iron or steel. The still is placed over a combustion chamber connected with a fire-grate. A coil of piping lies in the combustion chamber, and the heat from the fire, whilst acting directly on the bottom of the still, also superheats steam that is passed through the coil. The steam pipe is then led into the still and coiled within it, partially in the upper part and partially in the lower part, and then passes out of the still to a regulating valve or stop-cock, whence a pipe again enters the still, and proceeds centrally downwards nearly to the bottom, where the steam issues amongst the oil. A disc is fixed to the lower end of the pipe, to distribute the steam. "The steam is highly

heated when it first enters the still, but in passing through the coil in the still it yields part of its heat in an effective yet non-injurious manner through the pipes to the oil, and when it finally enters openly amongst the oil at the bottom pipe its temperature has become suitably reduced." Suitable valves are fitted, to permit of the steam being shut off from the coil and led directly into the oil, if desired. Drawings of apparatus accompany the specification.—H. S. P.

*Improvements in Treating Gases from Blast Furnaces, Gas Producers, and Coke Ovens, and in Apparatus therefor.* The Coltness Iron Company, Limited, Glasgow, and W. Young, Peebles. Eng. Pat. 17,673, November 6, 1889. 1s. 1d.

THE gases are first led into a dust chamber, where most of the dust is separated from them; the sooty tars are next separated by scrubbing with "watery tar," in which process the hot gases evaporate some of the water from the watery tars, and render them more suitable for distillation; and finally the ammonia and the more volatile oils still contained in the gases are separated by ordinary surface condensing apparatus, the last traces of ammonia being removed by washing and scrubbing the gases with water; or the ammonia may be recovered by scrubbing with sulphuric acid, or the tar and part of the ammonia recovered by cooling the gases to 100° F., after which the rest of the ammonia is separated by sulphuric acid. Drawings of suitable apparatus accompany the specification.

—H. S. P.

*Improvements in the Process of Producing Disinfectants.* A. Artmann, Braunsweig, and H. W. Kufeke, Hamburg, Germany. Eng. Pat. 20,231, December 16, 1889. 4d.

See under XVIII. C., page 1144.

*Improvements in Coke Ovens.* W. L. Wise, London. From L. Semet, Brussels, Belgium. Eng. Pat. 20,368, December 18, 1889. 4d.

IN order to ensure regular heating of a series of coke ovens, it is necessary that each oven should be supplied with an equal quantity of gas. Advantage is taken of the equal flow of gas through orifices of equal dimensions under the same pressure. With this object the gas in the main supply pipe is kept at a constant pressure, and to the end of each pipe connected with the ovens is attached a perforated diaphragm with equal-size orifices of the cross sectional area necessary to pass the required volume of gas at the regulated pressure.—A. W.

## IV.—COLOURING MATTERS AND DYES.

*On the Action of Aromatic Bases on Meldola's Blue.* R. Hirsch and F. Kulekhoff. Ber. 23, 2992—2994.

"New" blue is formed by the action of nitrosodimethylaniline on  $\beta$ -naphthol according to the equation:—

the hydrogen which is evolved in the reaction reduces part of the nitroso base and it is necessary to use 3 mols. of the base and 2 mols. of the phenol to obtain quantitative results. Experiments proved that the amidodimethylaniline which is formed in the reaction acts on Meldola's blue and produces a greenish blue colouring matter, identical with the one described by Witt (this Journal, 1888, 559—560). Other bases act as well on the colouring matter, and the author has studied the action of aniline, toluidine, and

naphthylamine on Meldola's blue. They proceeded in the following way: 1 part of the base is added to a boiling solution of one part of the blue (free from zinc) in 10 parts of alcohol and the boiling of the mixture is continued. After a very short time the violet colour changes to green and after half an hour the reaction is finished. On addition of caustic soda, and after cooling, the base will crystallise and is recrystallised from toluene. The product obtained from aniline melts at 256° C., forms brown needles and dissolves in concentrated sulphuric acid with a violet-brown colour. On gradual addition of water the colour of the solution changes at first to orange and finally a blue-violet precipitate is formed. The product from *p*-toluidine forms brown plates melting at 250° C. and resembles the aniline product very much. Its solution in sulphuric acid is greenish grey, but changes on dilution to orange, and forms finally a blue-violet precipitate.

The colouring matter obtained from  $\alpha$ -naphthylamine melts at 260° C., and dissolves in concentrated sulphuric acid with a yellowish brown colour, which on dilution changes to a bluish green, and finally precipitates the violet sulphate.

All colouring matters obtained from monamido bases are nearly insoluble in dilute mineral acids; the one prepared from *p*-amidodimethylaniline is, however, easily soluble, with a bluish-green colour. The yield of these new products is not more than 50 per cent. of the blue employed.

—A. L.

#### New Synthesis of Indigo and similar Colouring Matters.

K. Henmann. Ber. **23**, 3043—3045.

BAEYER observed that in some methods of preparing indigo a body must be formed as intermediate product, viz.:—

which he called *Pseudo-indoxyl*. All attempts to isolate it have however failed, it being at once converted by intramolecular change into—

The author intended to prepare Pseudo-indoxyl from phenylglycocine in the following way:—

All experiments in which phenylglycocine is treated with dehydrating agents as zinc chloride, concentrated sulphuric acid, &c. failed however; fusion with caustic alkalis proved at last successful.

If 1 part of phenylglycocine be fused with 2 parts of caustic potash, the presence of air being as much as possible avoided, the mixture is coloured yellow at about 260° C., and finally deep orange-brown. If then a sample is mixed with water, *pure indigo* is precipitated instantly on the surface of the water. If this point has been reached, the heating must be discontinued at once as the substance yielding indigo is destroyed by prolonged heating. After cooling, the substance is dissolved in water and a current of air passed through, when an abundant voluminous precipitation of *pure indigo* takes place. If the fusion is effected, air being entirely excluded, a yellow coloured vat is obtained, which also precipitates indigo at once when in contact with air.

Instead of caustic potash caustic soda may be used; but the reaction then requires the assistance of a slightly higher temperature.—A. L.

#### A New Synthesis of Indigo. L. Lederer. J. prakt. Chem. 1890, **42**, 383.

On heating phenylglycocine with 4—5 times its weight of fused caustic soda a pale yellow melt is first obtained, and this on further heating becomes of a pure orange, the colour indicating the completion of the reaction. On treating the product with a large bulk of water, *pure indigo* is obtained. Its formation is indicated thus:—

The intermediate product pseudindoxyl or indoxyl could not be isolated, and was probably oxidised directly to indigo-blue at the high temperature of the reaction.

—A. K. M.

#### On Naphtholsulphonesulphonic Acids and $\alpha$ -Naphtholsulphamidosulphonic Acids. A. Bernthsen. Ber. **23**, 3088—3096.

##### $\alpha$ -Naphtholdisulphonic acid—

forms an intramolecular anhydride of the Peri-series—

which on treatment with ammonia is converted into the sulphamide of the  $\alpha$ -sulphamidosulphonic acid  $\epsilon$ —

The anhydride, which the author calls  $\alpha$ -naphtholsultone-sulphonic acid, does not yield azo-colouring matters with diazo compounds, whilst the sulphamidosulphonic acid produces dyestuffs of remarkable properties when combined with diazo compounds.

##### The isomeric $\alpha$ -Naphtholdisulphonic acid $\delta$ —

can be converted into similar compounds; a sultone and a sulphamidosulphonic acid can be prepared from it. The  $\alpha$ -naphtholdisulphonic acid  $\delta$  is obtained in the following way: On nitration of naphthalene- $\alpha$ -sulphonic acid two nitro compounds (1, 5) and (1, 8) are formed, which on reduction produce two amido compounds. The 1, 8 acid forms a comparatively difficultly soluble sodium salt, by which it can be easily isolated. The amido compound is then either converted into the disulphonic acid, which is diazotised and gradually added to acidulated boiling water. After neutralising with lime, the calcium salt is converted in the usual way into the sodium salt of the  $\alpha$ -naphthol- $\delta$ -disulphonic acid. Or the 1, 8 amidosulphonic acid is

diazotised, the diazo compound boiled with water, acidulated by sulphuric acid. In this way the naphthol-sultone—

is obtained, which, on sulphonation, yields the sulphonic acid, and after treatment with calcium hydrate and sodium carbonate the sodium salt.

$\delta$ -Naphtholsultonesulphonic acid,  $C_{10}H_7\left\{ \begin{smallmatrix} O \\ SO_2 \end{smallmatrix} \right\} SO_3H$

is obtained by adding one part of naphtholsultone gradually to 8 parts of sulphuric acid containing 5 per cent. of sulphur trioxide. The acid requires to be cooled. After about an hour the mixture is poured into a mixture of 12 parts of ice and 16 parts of a saturated solution of sodium chloride, care being taken to stir well and to cool the containing vessel. The sodium salt of naphtholsultonesulphonic acid—

is precipitated and can be purified by recrystallisation. It forms thin plates and is much easier soluble in water than its  $\epsilon$ -isomeride.

The following table illustrates the differences between the sodium salts of the naphtholsultonesulphonic acid  $\delta$ , and the  $\alpha$ -naphthol- $\delta$ -disulphonic acid:—

Sodium Salt of.	$\delta$ -Naphtholsultonesulphonic Acid.	$\delta$ -Naphtholdisulphonic Acid.
Formula .....	$C_{10}H_7(OSO_2SO_3Na + 3 H_2O)$	$C_{10}H_7(OH)(SO_3Na)_2$
Solubility in $H_2O$	Comparatively small.	Very soluble in $H_2O$ .
Ferrie chloride produces.....	No colouration.	Blue colouration.
Solubility of barium salt in $H_2O$ .....	Very great.	Very slight.
Ammonia produces.....	Sulphamidisulphonic acid	No sulphamidisulphonic acid.
Diazo-compounds produce	No azo colour.	Azo colours.

The sodium salt of naphtholsultonesulphonic acid can be easily converted by the action of caustic alkalis, carbonates, calcium hydrate, by boiling with water or by boiling with water containing 5 per cent. of sulphuric acid into salts of the naphtholdisulphonic acid, or into the free acid. On treatment of the disulphonic acid with concentrated sulphuric acid at  $100^\circ C$ . the sultonesulphonic acid is reformed.

$\delta$ -Naphtholsulphamidisulphonic acid—

is obtained from the sodium salt of the before-described compound by mixing it with a concentrated solution of ammonia. An ammonia sodium salt is formed, and hydrochloric acid precipitates from its concentrated solution the sodium salt of  $\delta$ -naphtholsulphamidisulphonic acid.

The azo colouring matters obtained from this compound are very much like those obtained from its  $\epsilon$ -isomeride, but totally different from the derivatives prepared from the corresponding disulphonic acids. They are much bluer, as a rule less soluble in water, and most of them crystallise well. Their formula is  $RN:NC_{10}H_7(OH)(SO_3H)(SO_2NH_2)$ . The combination with aniline forms a bluish-orange, with xylylene a blue-scarlet, with  $\alpha$ -naphthylamine a claret-red, and with benzidine a blue-violet. The reduction of the aniline derivative proceeds according to the following equations:—

*Action of Alkalis on the Colouring Matters obtained from the Sulphamidisulphonic Acid.*—On boiling for a short time the bluish-red solution of the colouring matter produced by the action of diazoxylene on naphtholsulphamidisulphonic acid with an alkali or an alkaline carbonate, the colour of the solution changes to a light reddish yellow. Other colouring matters obtained from these sulphamidisulphonic acids show a similar reaction. New products have been formed, which, however, still contain the nitrogen atom of the sulphamido group. They dye wool from an acid bath much bluer than the original colouring matters, and the combination with aniline (after treatment with boiling alkali) is a bluish-scarlet, with  $m$ -xylylene a cochineal, with  $\alpha$ -naphthylamine a reddish-violet, and with benzidine a steel-blue. On reduction of the xylylene colouring matter, xylylene and a compound,  $C_{10}H_6N_2S_2O_5 + H_2O$ , is formed. The latter, which forms small needles, is probably—

The intra-molecular anhydride of an  $\alpha$ -naphthylenediamine-disulphonic acid. It can be converted into  $\alpha$ -naphthylenediamine, which produces an azine with phenanthrenequinone. The action of alkalis on the colouring matters obtained from sulphamidisulphonic acid is probably expressed by the equation—

*Action of Concentrated Sulphuric Acid on Colouring Matters Obtained from  $\alpha$ -Naphtholsulphamidisulphonic Acids.*—Concentrated sulphuric acid dissolves these colouring matters with a certain colour which, however, soon changes. In some instances colouring matters are formed identical with the products obtained from the corresponding  $\alpha$ -naphtholdisulphonic acid; in other cases more complicated products are the result of this reaction.—A. L.

*On Diphenyl Bases.* E. Noelting and P. Werner. Ber. 23, 3252–3266.

ONLY diparadiamido derivatives such as diphenyl benzidine, ortho-tolidine, &c. are capable of yielding substantive cotton dyes when diazotised and combined with phenols, amines, or their derivatives. Diphenylene, the by-product in the preparation of benzidine, which has an unsymmetrical constitution, fails to give substantive dyes, and the authors have prepared a considerable number of derivatives of diphenylene and substances of analogous constitution to ascertain whether they all resemble diphenylene in not giving those dyes.

*Di-tolylene* is a by-product in the preparation of ordinary tolidine. It is contained in the mother-liquors of the hydrochloride of the latter base. The sulphate is readily soluble in water, and the salts of the new base also differ from those of orthotolidine in being coloured by bromine water first a dirty green, which changes to a red-violet. It gives no substantive dye.

*Bromo- and Iododiphenylene* are obtained by first preparing the parabromo- or iodo-azobenzene from amidoazobenzene by Sandmeyer's method and reducing the alcoholic solutions of the azo compounds with stannous chloride. These diphenylene derivatives give azo dyes, which hardly have any affinity for unmordanted cotton.

When meta-iodohydrazobenzene is dissolved in hot concentrated hydrochloric acid, iodine separates as well as considerable quantities of benzidine.

By reducing azobenzene-*para*-sulphonic acid with sulphurated hydrogen in ammoniacal solution, Griess obtained a benzidine sulphonic acid. This acid, however, is actually

hydrazobenzene sulphonic acid. It cannot exist in the free state, as on adding hydrochloric acid to its salts, benzidine sulphate separates out.

*Diphenyl bases from Hydroxyazo Derivatives.*—The ethylic ether of hydroxyazobenzene can be converted into an ethoxydiphenyl base by stannous chloride and acid. The base yields no substantive dyes, and probably has an analogous constitution to diphenylene.

The preparation of *orthotolyl-azophenol* and *orthotolyl-disazophenol* is described, the former by the action of one molecule, the latter of two molecules of diazo-orthotolyl-chloride on an alkaline solution of phenol. The former is converted into the ethyl ether, which on reduction with  $\text{SnCl}_2$  in alcoholic solution yields a diphenyl base, colours from which do not dye unmordanted cotton. The corresponding paratolyl-azophenol derivatives is similarly prepared, from which the hydrazo compound is readily obtained. This, however, instead of being converted by acids into a diphenyl derivative is split up into an azo compound and monamines. The following substances are also described:—

*Phenylazo-ortho cresetol*, its hydrazo derivative *orthotolyl-azo-ortho cresol*, *orthotolylhydrazo-ortho cresetol*, *orthotolyl-disazo-ortho cresol* and its ethyl ether, *paratolylazo-ortho cresol* and the ethyl ether, *paratolylhydrazo-ortho cresetol*, *paratolyl-disazo-ortho cresol* and its ethyl ether.

In the azo derivatives of paracresol the para position is free. By reducing the ethers of these bodies in acid solution true benzidine derivatives are therefore produced which were patented by Geigy in 1887.

*Phenylazo-paracresetol* is prepared from phenylazo-paracresol, ethyl bromide and sodium alcoholate by heating their alcoholic solutions. By reducing in ammoniacal and alcoholic solution with sulphuretted hydrogen, the hydrazo compound is produced which with acids undergoes a change into *methylthorbenzidine*—

This base is capable of yielding substantive tetrazo dyes which have almost as perfect an affinity for unmordanted cotton as the usual benzidine derivatives. The shade in the ease of combination with  $\alpha$ -naphthol- $\alpha$ -sulphonic acid tends towards violet as compared with that obtained from the corresponding benzidine compound.

*Orthotolylazo-paracresol*, the cresetol derivative, and *orthotolylhydrazo-paracresol* are also described. From the latter *dimethylthorbenzidine* is readily prepared, which yields substantive cotton dyes.

*Paratolylhydrazo-paracresetol*, by treatment with mineral acids yields a diphenyl derivative which has an analogous constitution to diphenylene, as one para position is occupied in the azo compound. The dyes prepared from it consequently have hardly any affinity for cotton.—A. R.

#### Synthesis of a Diamidocarbazol from Benzidine. E. Täuber. Ber. 23, 3266—3269.

META-DIAMIDORENZIDINE, when heated for 10 hours with hydrochloric acid containing 18 per cent. of HCl from  $180^\circ$ — $190^\circ$  is converted into diamidocarbazol, ammonia being split off. This new compound, which has the composition—

is best separated as its sulphate, which is almost insoluble even in boiling water. It yields strong substantive tetrazo dyes for cotton of shades similar to those derived from benzidine, and in this respect closely resembles benzidine sulphone and diamidodiphenyloxide, which only differ from diamidocarbazol in having an  $\text{SO}_2$  or O in place of the

imido group. This diamidocarbazol is not identical with the one obtained by the "Badische Company" by reduction of dinitrocarbazol. The author also refers to the nomenclature of substituted benzidines.—A. R.

#### Orcein. K. Zulkowski and K. Peters. Monatsh. 11, 227—245.

THE authors have submitted pure orceinol to the action of ammonia and air, and have obtained three distinct dye-products, namely, *a*, orcein, which is the chief product; *b*, a yellow dye; and *c*, a dye resembling litmus. The two former were obtained crystalline, the last in an amorphous state. The same products are also obtained, and in a much shorter time, by the action of hydrogen peroxide and ammonia on orceinol. The first reaction is conducted as follows:—A solution containing 50 grms. of orceinol, 200 cc. of water, and 200 cc. of ordinary ammonia solution is put into a capacious flask, the mouth of which is then covered with a beaker. A granular precipitate is gradually formed, and in about two months the whole has become of a thick consistency. The greater part of the ammonia is then driven off by a gentle heat; the product is cooled, neutralised with hydrochloric acid until a distinct change of colour is produced, filtered, and washed with water. The precipitate contains all three dyes, and the red filtrate contains the yellow dye together with some orcein; the latter is concentrated and the dyes precipitated by the addition of salt. The separation of the crude product into its constituents is effected by extracting first with ether which dissolves the yellow dye, then with boiling alcohol which dissolves the orcein, the residue insoluble in spirit being the litmus-like substance mentioned. To obtain pure orcein the alcoholic solution is concentrated, diluted with an equal bulk of water, and set aside to crystallise; it is then filtered on the pump and dried in vacuo at the ordinary temperature. Pure crystallised orcein is insoluble in hot or cold water, in ether, benzene, chloroform, and carbon bisulphide, but is soluble in acetone, acetic acid, and alcohol; it dyes wool a beautiful amaranth red, its dyeing power being 150—200 times greater than that of orcein extract. Its composition agrees with the formula  $\text{C}_{23}\text{H}_{21}\text{N}_2\text{O}_7$ , and its formation may be expressed thus—

The yield amounted to about 50 per cent. of the weight of orceinol taken.

The yellow product is purified by crystallisation from a mixture of alcohol and water. It is sparingly soluble in cold, more readily in hot water, the best solvent, however, being alcohol. Its solution has an orange-yellow colour, which becomes deep violet on the addition of ammonia or caustic alkali. Its formation and composition are indicated by the equation—

The third substance being amorphous and insoluble has not been obtained pure. It exhibits a green metallic lustre, dissolves in alkalis to a deep blue solution resembling litmus, and, like the latter, the blue solution changes to red on the addition of acid.

The same three products appear to be formed when orceinol is oxidised by hydrogen peroxide in the place of atmospheric oxygen, but in this case the reaction is complete in three or four days. The proportions employed in this case were orceinol 100 parts, ammonia solution (22 per cent.) 200 parts, and hydrogen peroxide solution (3 per cent.) 1,200 parts.

An attempt to prepare a substance analogous to orcein by the action of ammonia and hydrogen peroxide on resorcinol yielded a negative result, the product in this case bearing more resemblance to litmus than to orcein. A mixture of resorcinol and orceinol in molecular proportions yielded on the other hand a substance  $\text{C}_{26}\text{H}_{20}\text{N}_2\text{O}_7$ , which the authors call *reso-orcein*, and which is analogous to

orcein. It dissolves readily even in dilute alcohol, the solution exhibiting a deep magenta colour though bluer than orcein.

A number of other dihydroxy- and trihydroxy-derivatives of benzene was likewise examined in the same direction, but no satisfactory results were obtained.—A. K. M.

*The Preparation of Ultramarine.* J. Wunder. Chem. Zeit. **14**, 1119—1123.

*On the Properties of the Natural Colouring Matters of Yellow Silk and their Analogy to those of Vegetable Carotene.* R. Dubois. Compt. Rend. **111**, 482—483.

THE following different dyes were extracted from silk naturally yellow. (1.) A golden yellow colouring matter soluble in potassium carbonate and reprecipitated by acetic acid. (2.) Crystals which appear yellowish-red by transmitted, and brown by reflected light. (3.) A lemon-coloured amorphous body. On evaporating its alcoholic solution granular masses separate. (4.) Yellow octohedral crystals resembling sulphur. (5.) A dark bluish-green pigment in minute quantities and probably crystallisable. Though these different substances were not obtained in a sufficiently pure state to draw conclusions as to their composition, the author observes that these dyes closely resemble those obtained from carotene.—A. R.

#### PATENTS.

*Improved Manufacture of Azoxyaniline and of Colouring Matters derived therefrom.* J. Inray, London. From "La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis," Paris, France. Eng. Pat. 20,219, December 16, 1889. 4d.

IF *p*-nitro-acetanilide, melting at 207°, be reduced with zinc powder and salt in an aqueous solution, it is converted into acet-azoxy-aniline of melting point 275°. This, on treatment with hot hydrochloric acid, yields the hydrochloride of azoxyaniline readily soluble in hot water and nearly insoluble in hydrochloric acid. The base, obtained from the solution of the hydrochloride by the addition of an alkali, is a yellow precipitate insoluble in water and crystallises from dilute alcohol in small needles melting at 185°. Colouring matters are obtained by diazotising the base and combining the tetrazo-compound with  $\alpha$ -naphthol- $\alpha$ -sulphonic acid or  $\beta$ -naphthol disulphonic acid. The products dye unmooranted cotton violet-red and bluish-violet respectively from an alkaline bath, and are said to resist acids.—T. A. L.

*The Production of a Substituted Meta-Diamine and of Colouring Matters derived therefrom.* J. Inray, London. From "La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis," Paris, France. Eng. Pat. 20,292, December 17, 1889. 4d.

BY heating together 10 kilos. of chloro-dinitro-benzene,  $C_6H_3Cl(NO_2)_2$  [ $Cl : NO_2 : NO_2 = 1 : 2 : 4$ ] with 7 kilos. of *m*-amidodimethylaniline on the water-bath, dinitro-*m*-amidodimethyldiphenylamine is obtained, melting at 136° and crystallising from alcohol in orange-coloured laminae. 15 kilos. of this product are then heated with 14 kilos. of nitrosodimethylaniline hydrochloride in an alcoholic or acetic acid solution. A colouring matter is soon formed and is precipitated by the addition of salt. It is purified by

redissolving in water slightly acidulated with hydrochloric acid and again adding salt, when it forms a crystalline brownish-red mass, which dyes wool, silk, and cotton mordanted with tannin, violet with a red fluorescence, visible in the case of cotton, in an artificial light. The dinitro condensation product may also be reduced with the ordinary reducing agents, yielding products which are also violet colouring matters.—T. A. L.

*Improvements in and relating to the Manufacture of Colouring Matters suitable for Dyeing and Printing.* J. Y. Johnson, London. From "The Badische Anilin und Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 20,668, December 23, 1889. 6d.

DIAMIDO-DIPHENYLENE ketone is combined with hydroxylamine forming diamido-diphenylene ketoxime. This substance, on treatment with nitrous acid, yields a tetrazo compound which combines with phenols, amines, their sulphonic and carboxylic acids, to form dyestuffs capable of dyeing unmooranted cotton orange, red, brown, purple or blue. The diamido-diphenylene ketone is obtained by mixing one kilo. of dinitro-diphenylene ketone with 10 kilos. of alcohol, and reducing with 10 kilos. of sodium sulphide ( $Na_2S + 9 H_2O$ ) at the boiling point of the liquid. The alcohol is then distilled off and the residue extracted with dilute hydrochloric acid, from which the base is precipitated by the addition of sodium carbonate. To produce the ketoxime, 21 kilos. of diamido-diphenylene ketone are dissolved hot in 1,600 litres of water and 35 kilos. of hydrochloric acid of sp. gr. 1.11. A concentrated aqueous solution of 10 kilos. of hydroxylamine hydrochloride is then added, and the whole allowed to cool down. About 63.5 kilos. of caustic soda lye of sp. gr. 1.38 are next added, and the temperature of the solution raised to about 70° and finally boiled. After filtering, the new base is carefully precipitated by adding about 44 to 48 kilos. of hydrochloric acid. The product is employed preferably as a paste, as unless carefully dried at a low temperature it is liable to undergo decomposition. In place of hydroxylamine hydrochloride its sulphonic acid may be employed, when the same product is produced. The conversion of the diamido body into its tetrazo compound is performed in the usual manner, and the latter may be combined with two molecules of the same or of different phenols or amines, &c.—T. A. L.

*Production of Compounds of the Diphenylmethane Group and the Rosaniline Series.* O. Inray, London. From "The Farbwerke vormals Meister, Lucius and Brüning," Höchst-on-the-Maine, Germany. Eng. Pat. 20,678, December 23, 1889. 6d.

WHEN formaldehyde is condensed with certain aromatic amines, there are formed derivatives of diphenyl-methane which on oxidation in presence of an aromatic amine yield colouring matters of the rosaniline series. By the action of formaldehyde on aniline, anhydroformalddehyde aniline  $C_6H_5N = CH_2$  is produced. 50 parts of this are heated with 70 parts of aniline hydrochloride and an excess of aniline on a water-bath with constant agitation when the mass becomes semi-liquid. After about 12 hours it is made alkaline, the excess of aniline distilled off with steam and the oil remaining solidifies to a crystalline mass of diamidodiphenylmethane which can be purified by crystallisation from benzene or water. It melts at 87°. Homologues of the compound are obtained by using homologues of aniline. All these compounds when oxidised together with an aromatic amine and hydrochloric acid yield colouring matters of the rosaniline series the oxidising agents being, nitro-benzene *o*- and *p*-nitro-toluene, nitro-xylene, salts of oxide of iron, arsenic acid, azobenzene and similar bodies. Formaldehyde also combines with secondary amines such as diphenylamine, and these substances on oxidation with an amine yield substituted rosanilines.—T. A. L.

*Improvements in the Manufacture of Raw Materials for Dyestuffs.* R. J. Friswell, London. Eng. Pat. 39, January 1, 1890. 4d.

A PROCESS for obtaining oxyazotoluidine from azoxytoluidine melting at 168° (obtained by the alkaline reduction of nitrotoluidine melting at 107°) by dissolving it in sulphuric acid of sp. gr. 1.84 and allowing the mixture to stand 24 to 140 hours at 15° to 60° C. By the addition of water the oxyazo compound is precipitated in the form of sulphate almost insoluble in water, and as an amido body can be used for the preparation of dyestuffs in the usual manner.

—T. A. L.

## V.—TEXTILES: COTTON, WOOL, SILK, Etc.

*On Silk Secretion by Bombyx Mori.* R. Dubois. Compt. Rend. 111, 206—207.

See under XXIII., page 1163.

*The Colouration of Silk by means of Coloured Food given to Silkworms.* L. Blanc. Compt. Rend. 111, 280—282.

VILLON and Blanchard have shown that by giving to silkworms coloured food—especially food coloured by indigo and madder—the silk of the resulting cocoons is coloured accordingly. The experiments of the author show that this colouration is only effected when the colour is used in the form of a powder, and is due to the colour being collected mechanically by the viscous material surrounding the threads of the silk. Soluble and readily diffusible colouring matters such as magenta, however, whilst they are capable of being absorbed by the intestinal epithelium of the silkworm and thereby colouring the secretive organs, do not colour the products of secretion—i.e. the resulting silk.—C. A. K.

See under IV., page 1124.

## VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

*Action of Aniline on Bleached Cotton.* S. Lipkowski. Chem. Zeit. 14, 1203.

KOECHLIN first, some years ago, suggested aniline as the cause of bleached cotton becoming tinted of a rose colour on lying for some time at the print works.

Aniline itself, however, is found not to bring about the phenomenon; only after a considerable time is bleached cotton tinted by aniline vapour, and then the colouration is brownish. But if, instead of aniline, a mixture, in certain proportions, of aniline salt, sodium chlorate, copper sulphide, or a hydrochloric acid solution of ammonium vanadate be employed, then after a period of from 18 to 24 hours a rose colouration is obtained on the goods. The active principle is thus not aniline itself, but its chlorate in the successive changes which this latter brings about under the action of hydrochloric acid, heat, light, &c.

Various sorts of material were experimented on, and it was found that the rose colour is especially developed on cotton from India; good American sorts give no colouration after 24 hours, and take only a faint yellowish tinge after 48 hours.

The bleaching operations are not without effect on the intensity of the colouration; excessive contact with chlorine water, for instance, and insufficient washing, leave the goods in a state conducive to the formation of the colour.—T. L. B.

*Flavin and its Preparation.* V. H. Soxhlet. Chem. Zeit. 14, 1345—1346.

FLAVIN is a light brownish yellow to deep orange yellow powder, chiefly used for obtaining yellow and orange shades on wool. It is also employed for dyeing vegetable fibres by using alumina mordants in conjunction with it. The dye is almost exclusively made in America by extracting quercitron bark with alkaline aqueous solutions under pressure. The solutions are rendered alkaline either by the addition of soda or borax or ammonia. After very careful filtration of the extracts, so much weak acid, preferably a mixture of hydrochloric and sulphuric acids, is added to produce complete saturation, and the mixture is then boiled. By this treatment it is assumed that the quercitrin is split up into quercetin and a sweet body, possibly isodulcite, the latter, along with the tannin, remaining in solution. The extract, after treating with acid, is filtered hot, and the press cakes dried and ground. The yield, according to the purity of the final product, varies from 4—10 per cent. The dye should not be entirely soluble in boiling water; on adding aluminium sulphate no precipitate should be produced, but the colour of the solution must alter to bright yellow. Aqueous solutions of the dye, if exposed to the air a few days, lose their tinctorial power entirely.

By the action of strong nitric acid flavin is converted into a much stronger dye, but of a different shade.—A. R.

*The Fixation of Insoluble Azo Dyes on Cotton Fibre in Calico Printing.* H. Schmid. Chem. Zeit. 14, 1406—1407.

It is well known that up to the present time it has been found impossible to render cotton fabrics dyed with commercial azo dyes, such as Ponceaux, Bordeaux, &c., fast towards soap. Most of these colours are dissociated from the fibre by water alone. A certain improvement was recently effected by Koehlin, who employs as mordant a mixture of several oxides, such as aluminium, magnesium, and zinc oxides. Still the dyes fixed by this means are attacked by soap. The use of a mordant rendering the azo dyes "soap fast" would certainly be preferable to any process of synthetically producing an insoluble non-sulphonated dye on the fibre itself. A number of methods embodying the latter principle have been patented during the last 10 years, but most of them are open to various drawbacks. One of the best processes which has stood the test of practice is to prepare the fabric with sodium  $\beta$ -naphtholate, the design being subsequently printed on the material by means of a thickened solution of a diazo salt (such as diazotised  $\alpha$ -naphthylamine). The chief objections to the method are:—1, the ease with which the diazo salt decomposes with evolution of nitrogen; 2, that the material prepared with sodium  $\beta$ -naphtholate may not be long preserved; and, 3, that the printed fabric must be at once finished in order to preserve the purity of the whites.

Nine years ago the author devised an improved process, the details of which have only now been published. It consists in preparing the fabric with a solution of sodium nitrite, the material being afterwards printed on by a mixture of a naphthol, an amine, and acid. For example, in order to produce Xylidine ponceau (Ponceau R.), a mixture of 25 parts of xylidine, 46 of hydrochloric acid of 20 B., 30 of  $\beta$ -naphthol, 80 of alcohol, 50 of water, and 250 of gum solution, is employed for printing, the fabric being previously treated with a solution of sodium nitrite containing 35 grms. per litre. After printing the colour is developed by an

ammoniacal steam bath; or the latter operation may be avoided by substituting for one-half of the hydrochloric acid in the recipe given below an equivalent amount of some volatile organic acid. Bright reddish-orange colours of considerable stability are obtained by the above process. If the xylidine be replaced by  $\alpha$ -naphthylamine, Garnet and Bordeaux red tones are obtained. By employing various mixtures of xylidine and  $\alpha$ -naphthylamine, a whole range of colours from orange red to dark red may be produced.

*Recipe for Bordeaux.*

- 84 grms. of  $\alpha$ -naphthylamine.
- 87 grms. of  $\beta$ -naphthol.
- 560 grms. of nitric acid at 36° B.
- 100 grms. of water.
- 560 grms. of alcohol of 90 per cent.
- 1,700 grms. of gum Senegal.

Preparation of the fabric: 40–50 grms. of sodium nitrite per litre.—H. T. P.

*Diamine Black R.* Oesterr. Woll- u. Leinen- Ind. 1890, 462.

This new dyestuff gives shades varying from grey to black, according to the amount used. It is applied on cotton in a boiling bath containing soda, sodium sulphate, or sodium phosphate. The shades produced are fast to light and soap. In common with other dyes of the benzidine class, Diamine black possesses the property of itself acting as a mordant for basic dyes, such as Safranine, Thioflavine, &c., and may, therefore, be usefully employed for producing compound shades with the latter class of dyes, as well as for darkening shades produced with other substantive colouring matters.

Silk is dyed with Diamine black under the addition of acetic acid to the dye-bath. The cotton portion of mixed goods composed of silk and cotton is alone dyed when an addition of soap is made to the dye-bath; the silk may be afterwards dyed another colour.—E. B.

*Diamond Black.* Chem. Zeit. Rep. 1890, 165.

*Diamond Black* may be dyed on wool in two ways: first, after mordanting with potassium bichromate and oxalic acid, when the dyestuff (1–2 per cent.) is applied along with 2 per cent. of acetic acid in the dye-bath; or second, in a single-bath containing 5 per cent. of nitrate of iron. The colour is developed on the temperature of the bath approaching boiling.

This dyestuff may be used in conjunction with other members of the alizarin group to produce compound shades. The shades it yields are extremely fast to acids, light, stoving, and milling. Silk and gloria-fabrics are dyed like wool.—E. B.

*Rubramine.* Chem. Zeit. Rep. 1890, 165.

This basic dye yields fine red shades on cotton mordanted with tannic acid, but also dyes unmordanted cotton if sodium acetate be added to the dye-bath. Wool and silk are dyed in a neutral or faintly acid bath.—E. B.

*The Production of Azo-Dyes on Cotton Piece-Goods.* H. Koechlin and G. Galland. Agenda du Chimiste, 1890.

The cloth is padded with a solution of 25 grms. of  $\beta$ -naphthol and 25 grms. of caustic soda at 38° B. per litre of water, then dried by hot air and passed for half-a-minute into one of the following developing baths:—

*For Pale Orange-Yellow.*—12.5 grms. of aniline, 25 grms. of hydrochloric acid, and 250 cc. of water are mixed, and then there is added a mixture of 9.5 grms. of sodium nitrite, 250 grms. of ice, and 250 cc. of water, and finally a solution of 100 grms. of sodium acetate in 250 cc. of water.

For other colours the aniline in the above recipe is replaced by other amido compounds, and the quantity of sodium nitrite is modified as below:—

*Orange.*—12.5 grms. of *p*-toluidine, 8.5 grms. of sodium nitrite.

*Orange-Red.*—10 grms. of *p*-nitraniline, 5.5 grms. of sodium nitrite.

*Scarlet.*—12.5 grms. of xylidine, 7 grms. of sodium nitrite.

*Red.*—10 grms. of  $\beta$ -naphthylamine, 6 grms. of sodium nitrite, and 50 grms. of sodium acetate.

*Deep Red.*—10 grms. of amidoazobenzene, 5 grms. of sodium nitrite.

*Dull Red.*—12 grms. of  $\alpha$ -naphthylamine, 7.5 grms. of sodium nitrite.

*Chocolate.*—10 grms. of benzidine, 5 grms. of sodium nitrite.

*Purple.*—7.5 grms. of dianisidine (sulphate), 3.25 grms. of sodium nitrite.

*Rose.*—10 grms. of naphthionic acid, 6 grms. of sodium nitrite, and 50 grms. of sodium acetate.

*Blue.*—1 litre of 10 per cent. solution of Safranine and 75 grms. of hydrochloric acid are mixed together, and there are successively added to the same a solution of 20 grms. of sodium nitrite in 250 cc. of water, mixed with 250 grms. of ice, and 250 grms. of sodium acetate dissolved in 2 litres of water.

A red is also produced by preparing the cloth with the following solution: 25 grms. of  $\alpha$ -naphthol and 30 grms. of caustic soda at 38° B. per litre of water, and, after drying, developing in a bath prepared with 10 grms. of  $\beta$ -naphthionic acid, 25 grms. of hydrochloric acid, and 250 cc. of water, to which are added in succession sodium nitrite (quantity not given in original) dissolved in 250 cc. of water and mixed with 250 grms. of ice, and 100 grms. of sodium acetate dissolved in 250 cc. of water.

The reds obtained with *p*-nitraniline and  $\beta$ -naphthylamine may be darkened by boiling with a solution of copper sulphate containing 2 grms. of the salt per litre.

In calico-printing the cloth is prepared with the alkaline naphthol solution, dried and printed with one or more of the diazo-derivatives prepared as above and suitably thickened, or a resist-colour containing 600–800 grms. of stannous chloride per litre of gum-solution may be first printed and the diazo-mixture padded over it.—E. B.

*Use of Nitroso-Compounds in Dyeing and Printing.* G. Ulrich. Mittheil. des k.k. Gew.-Museums, 1890, 47–59.

UNTIL quite recently the only nitroso-compounds finding employment for dyeing and printing were Naphthol green B (ferrous salt of nitroso- $\beta$ -naphtholmonosulphonic acid) and Resorcinol green (dinitrosoresorcinol). Later, however, several other nitroso-derivatives have been introduced, as, for example, the Gambines R and Y ( $\beta$ -nitroso- $\alpha$ -naphthol and  $\alpha$ -nitroso- $\beta$ -naphthol), nitrososalicylic acid, dinitroso-naphthoresorcinol, and *o*-naphthoquinonoxim; in fact, as Kostanecki shows, all ortho-quinonoxims and their substitution derivatives have colouring power.

*Naphthol green B.* comes into commerce as a dark green powder. Its aqueous solution gives the following reactions: Stannous chloride, acidulated with hydrochloric acid, decomposes it in the cold; oxidising agents, such as chromic acid, readily destroy it, even copper sulphate at the boil affecting it injuriously. It dissolves in strong sulphuric acid, with a yellow colour. On the fibre it shows, at a high temperature, little resistance to acids. In spite of this fact, most treatises on dyeing recommend the addition of acid to the dye-bath. The waste of colouring matter due to this cause is of little moment in the case of dark shades, but it is otherwise when pale shades are being dyed, with which the effect of a slight variation in the proportion of acid added to the bath is readily seen. In consequence of this, the author has sought to modify the method of dyeing. The following is a summary of the results of experiments made with this object:—

1. The colouring power of the dissolved dyestuff is quickly reduced, probably owing to oxidation, this action

being accelerated by the presence of acid and by heating. Experimenting with additions of various proportions of sulphuric acid, it was found that the quantity of this acid required for the decomposition of the dyestuff at a given temperature, varied inversely as the duration of action; thus, the addition of 1·166 grms. of sulphuric acid, diluted with water (10 grms. at 66° B. per litre) to a litre of dye solution containing 0·166 grm. of dyestuff, and maintained at the boil, effected its decolouration in three seconds, whilst 0·266 grm. of sulphuric acid (diluted at the same rate) added to another similar portion of the dye solution, had to be boiled 60 seconds with it to produce the same effect. The proportion of acid, however, required for decomposing the dyestuff at a given temperature is not constant, varying with the strength of solution of the latter. 0·33 grm. of sulphuric acid decomposed a litre of dye solution containing 0·016 grm. of dyestuff, and 0·366 grm. of the same acid sufficed to decompose a litre of dye solution 10 times as strong, the temperature in each case being 80°.

2. Under otherwise similar conditions, acetic acid acts injuriously at temperatures 20° higher than does sulphuric acid.

3. The addition of sodium sulphate in moderate amount raises the stability of the dyestuff at temperatures of 80° upwards.

4. Addition of ferrous sulphate tends to preserve the dye at temperatures below 80°. Ferric salts act injuriously.

5. Acetic acid in the presence of ferrous and sodium sulphates acts less destructively than sulphuric acid under the same conditions.

From further experiments it was ascertained that the best temperature for dyeing with this colouring matter was about 80°, and that the most suitable proportions of assistants for 0·5 part of dyestuff were 10 parts of Glauber's salt, 10 parts of ferrous sulphate, and two parts of sulphuric, or four parts of acetic acid.

Copper or tin dye-baths cannot be used, as these metals are attacked. In view of these objections and difficulties, the author considers it preferable to first mordant the woollen material, and then to rinse and dye it in a separate bath, to which sodium acetate is added.

**Nitroso-β-naphthol.**—The author recommends the following method of dyeing cotton with this colouring matter: the material is impregnated with an alkaline solution of the colouring matter, prepared by dissolving 5 parts of nitroso-β-naphthol and 5 parts of caustic soda (80 per cent.) in 90 parts of water; after "hanging," the material is worked in or passed through a fixing-bath corresponding to the shade desired, and composed of: for olive-green, a 5 per cent. solution of ferrous sulphate; for chocolate, a 2 per cent. solution of cobalt sulphate; for orange-yellow, a 2 per cent. solution of nickel sulphate. The goods may then be rinsed, dried, and finished.

The colour on the iron mordant is not fast to soap or dilute acid; those on the nickel and cobalt mordants are satisfactory in these respects.

The above method is applicable to printing; 5 parts of nitroso-β-naphthol and 5 parts of caustic soda (80 per cent.) are dissolved in 30 parts of water, thickened with 60 parts of dextrin solution (30 parts of dextrin in 30 parts of water), printed on, the cloth dried at a low temperature, and passed through one of the above-mentioned fixing-baths to develop the colour.

**Nitrosophenol** was experimented with, but no results of importance obtained.

**Dinitrosoresorcinol** (Syn. Fast myrtle, Resoreinol green, Alsaec green).—Excellent results are obtained with this colouring matter by the method described for nitroso-β-naphthol. For pale shades, the cotton material is prepared in a solution of 10 parts of the dyestuff in 10 parts of caustic soda (80 per cent.) and 980 parts of water. For dark shades a solution five times as strong is used.

The colours are produced by passing the material so prepared through one of the following solutions: for dark blue-green, 10 per cent. solution of ferrous sulphate; for chocolate, 5 per cent. solution of cobalt sulphate; for yellow-brown, 5 per cent. solution of nickel sulphate. The shades are similar to those yielded by nitroso-β-naphthol but for

equal amounts of dyestuff, much more intense. The cobalt and nickel colours are absolutely fast to soap; the iron colour is not perfectly fast, but faster than when produced by the customary method. The ordinary method of dyeing with this colouring-matter also labours under the disadvantage that some of the colouring matter is wasted, being decomposed at the high temperature of the bath.

For printing, 5 parts of dinitrosoresorcinol are dissolved, by the aid of an equal weight of caustic soda (80 per cent.) in 30 parts of water and mixed with a thickening composed of 30 parts of dextrin and 30 parts of water. The thickened mixture is printed and the colour-lakes produced as above described. This standard colour mixture, when reduced 1 : 15 to 1 : 63 and fixed by cobalt, yields delicate brownish tints, which may well replace the more expensive similar shades obtained with alizarin-orange.

**Nitrososalicylic Acid.**—Dye tests were made with a crude specimen of this compound prepared by adding sodium nitrite to an acidulated solution of sodium salicylate. No results of any value were obtained; ferric salts yield myrtle, and ferrous salts brown shades, by the above-described alkaline method, but only the latter are even moderately fast to soap. As the tests, however, were made with an impure product, they cannot be accepted as conclusive.

—E. B.

## VII.—ACIDS, ALKALIS, AND SALTS.

*A Double Salt of Dithionic Acid.* G. Bødländer. Chem. Zeit. **14**, 1140.

The author has succeeded in preparing a double salt of dithionic acid containing barium and rubidium according to the following formula:— $\text{BaRb}_4(\text{S}_2\text{O}_6)_3 \cdot 11\text{H}_2\text{O}$ . This compound crystallises in bunches of extremely small white needles, which polarise light; its solubility in water at 15° being 10·34 per cent.

The formation of this double salt is of interest, as Kolbe (J. prakt. Chem. [2], **19**, 485) has asserted that dithionic acid is monobasic, its true formula being  $\text{HSO}_3$ . Fock (Zeits. f. Krystallogr. **14**, 361) has described a dithionate of ammonium and aluminium having the formula—

but other attempts to prepare similar compounds appear to have been unsuccessful.—F. H. L.

*Hydrated Neutral Aluminium Sulphate; Analysis of a Natural Product.* P. Marguerite Delacharloumy. Compt. Rend. **111**, 229—231.

The author has shown that the formula of hydrated neutral aluminium sulphate is  $\text{Al}_2(\text{SO}_4)_3 \cdot 16 \text{H}_2\text{O}$ , and not  $\text{Al}_2(\text{SO}_4)_3 \cdot 18 \text{H}_2\text{O}$  as formerly supposed. Further he has examined two samples of a naturally occurring neutral aluminium sulphate, both of them beautifully crystalline, with the result that their composition also corresponds to the formula  $\text{Al}_2(\text{SO}_4)_3 \cdot 16 \text{H}_2\text{O}$ . This body, like that prepared in the laboratory, is characterised by a tendency to lose water. The naturally occurring product was embedded in a matrix of a basic sulphate of aluminium which had resulted from the decomposition of the neutral salt.—C. A. K.

*Equilibrium and Reciprocal Displacements of the Volatile Alkalies.* Berthelot. Compt. Rend. **111**, 289—296.

This paper is only of theoretical interest.—T. L. B.

*The Wilde and Reyhler Chlorine Process.* Industries, December 5, 1890, 556.

THE new process is based on the decomposition of hydrochloric acid in the following conditions:—When equivalent weights of crystalline magnesium sulphate ( $\text{MgSO}_4 \cdot 7 \text{H}_2\text{O}$ ), magnesium chloride ( $\text{MgCl}_2 \cdot 6 \text{H}_2\text{O}$ ), and manganese chloride ( $\text{MnCl}_2 \cdot 4 \text{H}_2\text{O}$ ) are heated together, they first dissolve in their water of crystallisation and then give off hydrochloric acid gas, leaving a pink hygroscopic mass consisting of a mixture of magnesium sulphate, manganese chloride, and magnesium oxychloride, entirely free from water. When heated to dull redness in a current of air in a muffle, this mixture evolves a further quantity of hydrochloric acid gas and chlorine, and leaves a black porous residue containing magnesium sulphate and a magnesium manganite of the composition  $\text{Mg}_3\text{Mn}_2\text{O}_8$ . The porous lumps formed in this way are introduced into an earthenware tube surrounded by a thin iron sheeting, and are heated to a temperature of about  $450^\circ \text{C}$ ., either directly or by means of a regenerative furnace. This tube is connected with two iron tubes, through one of which hydrochloric acid gas is led after it has been treated in a separate furnace, and through the other a current of air passes which has also been heated to the same temperature. The further end of the cylinder has also a tube attached to it which carries off the chlorine gas produced in the cylinder by the joint action of the air and hydrochloric acid passing over the heated magnesium manganite. The plant necessary for heating the gases introduced into the cylinder in which the reaction takes place has no special form; in fact, any plant at present in use for heating the air of a blast furnace can be used. The part played by the magnesium sulphate in the reaction, other than that of preventing the fusion of the mass, and thus maintaining its porous nature, is not known. Apparently the change that takes place consists in the alternate chlorination and oxidation of the magnesium manganite. These changes may be theoretically expressed by the following equations:—

In practice, however, the above reactions go on simultaneously, and the hydrochloric acid gas is not entirely decomposed, there always being a small percentage of this gas in the gases passing out of the cylinder in which the reaction takes place. The authors have investigated the conditions under which the maximum yield of chlorine is available, and have found that it not only varies with the temperature of the reacting compound, but depends also on the relative amounts of hydrochloric acid gas and air, and the rate at which the mixed gases pass through the cylinder.

It will be noticed that although the process is an alternating one, yet chlorine is evolved at both stages, and that therefore the method may be considered to be just as continuous as the Deacon process. The Brin's oxygen process, as now worked, offers a similar example of two alternate reactions taking place apparently at the same temperature. It may, however, be found more economical to employ two cylinders so heated that one shall be in the chlorinating stage while the other is in the oxidising stage, and thus secure a constant rate of production of the chlorine gas. The inventors point out that the cost of fuel and of labour is less than in the Deacon process, and the plant is much simpler than that used by the Péchiney method. The manganite is found not to require renewal for a long while, and then only a little is needed at a time, and the high percentage of chlorine in the gas which is evolved renders it possible to prepare directly therefrom bleaching powder of high chlorine content. The plant erected at MM. de Naeyer et Cie's works has now been at work some time, and has proved capable of continuously decomposing 76 per cent. of the hydrochloric acid used, and of the remainder four-fifths have been recovered and utilised in the process.

# PATENTS.

*Improvements in the Recovery of Chlorine from the Residual Liquors of the Ammonia-soda Process, from Solutions of Calcium Chloride, from certain Impure Solutions of Magnesium Chloride, and from some other Industrial Residues.* F. M. Lyte, London, and J. G. Tatters, Runcorn. Eng. Pat. 17,217, October 30, 1889. 6d.

"THE object of this invention is the production in the free state of the whole or nearly the whole of the chlorine contained in the calcic chloride resulting from the ammonia-soda process, in the magnesic chloride contained in the mother-liquors of salt works and the liquor from the treatment of carnallite, and in the hydrochloric acid or calcic chloride from the Leblanc or Weldon processes respectively."

The process depends upon the production of anhydrous magnesium oxychloride, of varying composition, from anhydrous ammonium-magnesium double chloride, the chlorine being evolved from the oxychloride in the ordinary way by passing over it air or oxygen while it is maintained at a suitable temperature.

In treating ammonia-soda waste liquors the two following methods of working are described, but the process admits of various other modifications. The liquor which remains after distilling off the ammonia with lime in the ammonia soda process is the liquor to be dealt with. It consists chiefly of calcium and sodium chlorides. In both the methods described this liquor is first freed from sodium chloride, and this is effected by concentrating it until "on cooling to ordinary temperatures, the calcium chloride it contains would form a saturated solution, or till the boiling point rises to  $110^\circ \text{C}$ . or thereabouts." During the evaporation most of the sodium chloride is deposited and the rest separates on allowing the liquor to cool and repose. This depends upon the insolubility of sodium chloride at ordinary temperatures in a concentrated solution of calcium chloride. Potassium chloride may be separated in the same way but not quite so completely. According to the first mode of working a sufficient quantity of soft burnt magnesia is added to this purified calcic chloride solution, and it is at the same time diluted to about 1.2445 sp. gr. at  $15^\circ \text{C}$ . By treatment with carbonic acid the lime is then precipitated and a solution of magnesium chloride obtained. To this is added sufficient ammonium chloride (obtained subsequently by sublimation from the anhydrous double ammonium magnesium chloride) to form ammonium magnesium chloride, and the solution of this salt is then evaporated to dryness and desiccated. On heating this salt, ammonium chloride volatilises and is used for making a fresh batch of the double salt, and anhydrous magnesium chloride remains. This is fused or ground and mixed with a sufficiency of dry magnesia (left from a previous generation of chlorine) and agglomerated by heating in a closed vessel, forming anhydrous magnesium oxychloride which may be broken up and used for generating chlorine. The patentees claim that whereas Péchiney recovers only 40.14 per cent. of the chlorine contained in his oxychloride, they on the other hand obtain about 60 per cent. of the chlorine in their anhydrous oxychloride, and that they avoid the cooling of the furnace caused by the evaporation of the water contained in Péchiney's oxychloride.

The patentees consider the second mode of working the most important. After obtaining the calcium chloride solution free from sodium chloride, it is saturated with ammonia and carbon dioxide, which produces a solution of ammonium chloride and precipitates the lime as carbonate. The solution of ammonium chloride is then mixed with sufficient magnesium chloride and evaporated to dryness. The dry ammonium magnesium chloride thus formed is then heated with magnesia, at a temperature not exceeding  $300^\circ \text{C}$ ., under which conditions magnesium chloride is formed and ammonia evolved according to the equation—

On subsequently raising the temperature to  $400^\circ \text{C}$ . or  $500^\circ \text{C}$ . a further reaction takes place between the magnesium chloride and the water formed at the lower temperature according to the equation—

Half the magnesium chloride being decomposed with the formation of magnesia and evolution of hydrochloric acid. "By this second heating, if the fusing point of magnesium chloride be attained, the magnesium chloride and magnesia formed will agglomerate entirely into an oxychloride, varying in composition according to the amount of magnesia present." This oxychloride may then be used in the ordinary way to generate chlorine. By this mode of working, therefore, besides the production of magnesium oxychloride, all the ammonia used in the process is recovered, and may be used for again saturating the calcium chloride liquor, and also the hydrochloric acid recovered may be passed into a milk of magnesia, forming magnesium chloride, to be again used for mixing with the ammonium chloride solution to produce the double chloride.

The heating may be done in a closed iron vessel as, provided all air is carefully excluded, no chlorine is evolved, and neither anhydrous hydrochloric acid nor ammonia has any action on hot iron. A small excess of magnesia and stirring the mixture assists the operation.

Both modes of working may be applied to recover chlorine from the hydrochloric acid of the Leblanc process, and from the calcium chloride from the Weldon process, but not so advantageously. In the case of hydrochloric acid, one half of the acid taken is neutralised with ammonia and the other half with magnesia or magnesite. When clear the two solutions are mixed, forming a solution of the double salt, from which ammonia, hydrochloric acid, and magnesium oxychloride can be obtained successively, as already described. The oxychloride yields chlorine and magnesia, the latter of which, with the ammonia, can be again used for saturating hydrochloric acid.

In treating the impure magnesium chloride contained in the mother-liquors of salt works and the liquor from the treatment of carnallite, the whole of the magnesium contained in the liquors as magnesia is precipitated by the addition of lime. The resulting solution of calcium chloride is then freed from sodium or potassium chloride by concentration, whilst the precipitated magnesia is washed free from sodium and potassium chlorides and returned to the purified solutions of calcium chloride, which is then diluted and treated with carbon dioxide. This throws down the lime and gives a pure solution of magnesium chloride, as described in the first method of working, or the pure calcium chloride solution may be worked according to the second method described (see following abstract).—H. S. P.

*Improvements in the Production of Hydrochloric Acid from certain Industrial Residues, together with the Recovery of Sulphur and Oxide of Magnesium.* F. M. Lyte, London, and J. G. Tatters, Runcorn. Eng. Pat. 17,218, October 30, 1889. 6d.

ANHYDROUS magnesium chloride or oxychloride is produced from the waste calcium chloride liquors of the ammonia-soda process, according to the method described in Eng. Pat. 17,217 (preceding abstract). Sulphuretted hydrogen is also produced from the soda waste of the Leblanc process as follows:—The waste "is to be mixed with water until it marks about 50° Tw., and then run into closed iron cylindrical vessels. Carbonic acid is then pumped through it, as in Chance's process." The sulphuretted hydrogen, together with just sufficient air, is then passed over magnesium chloride or oxychloride, heated to 600°–800° F., so that the decomposition of the chloride or oxychloride is effected without the formation of sulphurous acid or leaving any sulphuretted hydrogen unburnt. Gaseous hydrochloric acid and sulphur pass over. The sulphur is condensed in brick chambers, while the hydrochloric acid passes on, and may be either used in the gaseous state or may be condensed in the usual way.—H. S. P.

*Improvements in and Relating to Chemical Fire-extinguishing Compounds.* C. M. Martin, Washington, U.S.A. Eng. Pat. 17,517, November 4, 1889. 4d.

THE compound is made of 60 lb. of sodium chloride, 30 lb. of "sodium hyposulphate," 6 lb. of sal-ammoniac, 2½ lb. of magnesium sulphate, ½ lb. of magnesium chloride, ½ lb. of calcium oxide, and ½ lb. of iron oxide. The mixture is "dissolved in water" in the proportion of 3 lb. to a gallon of water. "When thrown on a fire it at once emits sulphurous acid gas in combination with free chlorine and ammoniacal gas, which instantly extinguishes the flames." —H. S. P.

*Improvements in the Manufacture of Alum.* F. M. Spence and D. D. Spence, Manchester. Eng. Pat. 17,888, November 9, 1889. 6d.

THE inventors use the following plan to form well crystallised soda alum, a body much harder to obtain in this condition than the corresponding ammonia and potash alums. A hot highly-concentrated solution of the alum, produced by dissolving in aluminio-ferrie sulphate the proper amount of salt cake, is run into a cold concentrated solution of the same salt in the proportion of two to one, a magna being produced upon cooling. This is thoroughly stirred and turned over, crystals of the alum being gradually formed which may now be readily separated by known means from the mother-liquors. These latter, after the removal of an amount containing iron equal to that introduced by the hot concentrated solution, constitute the cold concentrated solution already mentioned.—S. G. R.

*Improvements in the Treatment of Copper or Cupreous Compounds for the Production of Sulphate of Copper and the Extraction of the Precious Metals, and in Apparatus applicable therefor.* T. Haeghe, Briton Ferry, and "The Cape Copper Company, Limited." Eng. Pat. 18,297, November 15, 1889. 8d.

See under X., page 1134.

*Improvements in or connected with the Manufacture or Production of Ammoniacal Salts.* E. Bowen, Swansea. Eng. Pat. 18,356, November 16, 1889. 4d.

INSTEAD of passing steam into the mixture of lime and ammoniacal liquor, heated air is blown in. It is found that the resulting mixture of vapours will completely precipitate the iron (ferrous) in solution in acids such as sulphuric or hydrochloric, a clear solution of the ammoniacal salt being obtained, a result which is not attained by the usual method. The air may be heated by the waste heat derived from the ammonia still.—S. G. R.

*Improvements in the Manufacture of Hypophosphites.* J. A. Kendall, London. Eng. Pat. 20,392, December 18, 1889. 4d.

IN order to obtain the hypophosphites of various metals it has been found to be more advantageous to incorporate charcoal with the phosphorus before the addition of the latter to the milk of lime or other hydrate used. The charcoal or powdered coke is made into a thin cream with water and mixed by means of heat and agitation with the phosphorus. When cool the mixture is heated with the desired hydrate till the reaction is complete.—S. G. R.

*Improvements in obtaining Chlorine.* W. Donald, Salt-coats. Eng. Pat. 5488, April 11, 1890. 8d.

The chlorine is generated by passing hydrochloric acid gas into a mixture of nitric acid and sulphuric acid, cooled by cold water or by brine at, or a little below, the freezing point. The chlorine and nitric peroxide thus formed then pass into another vessel containing nitric acid, and a second stream of hydrochloric acid gas is also introduced into this vessel. The chlorine is finally purified by passing through a nitric acid scrubber and by washing with sulphuric acid. The nitrous acid formed may be oxidised in any well-known way, either in separate apparatus or by introducing air with the hydrochloric acid, or with the mixture of chlorine and nitric peroxide.

Drawings of a suitable apparatus accompany the specification. (See also this Journal, 1887, 822; and 1890, 389.) —H. S. P.

*Improvements in and relating to the Manufacture of Carbonates of Alkalis and Acetone.* F. W. A. Frerichs, St. Louis, U.S.A. Eng. Pat. 9793, June 24, 1890. 4d.

CALCIUM acetate is mixed with potassium sulphate in equivalent proportions and after filtration the potassium acetate formed is evaporated to dryness and destructively distilled with the evolution of acetone, potassium carbonate remaining behind in the retort. Barium and strontium acetates and sodium sulphate may also be employed.

—S. G. R.

*Process for obtaining Chlorine and Bromine by the Aid of Electricity.* G. Nahsen, Hanover, Germany. Eng. Pat. 11,699, July 26, 1890. 4d.

See under XI., page 1136.

## VIII.—GLASS, POTTERY, AND EARTHENWARE.

*The Cause of the Iridescence of Table Glass.* A. Jolles and F. Wallenstein. Sprechsaal, 23, 685.

THE iridescent film in glass is partially soluble in water, the remainder being unattacked by hydrochloric acid, but yielding easily to caustic soda. Both solutions contain sodium, sulphuric acid and carbonic acid. The portion insoluble in acid can only be silica, no lime being found even by the spectroscope. The film exists only on one side of the glass, and must be formed during the final heating, being probably caused by the sulphurous acid in the burning gases, which acts on the surface of the glass, forming sodium sulphate and silicate, the latter being subsequently decomposed into free silica, which separates out in the amorphous form.

—F. H. L.

*Note on the Production of Kaolin.* A. Simon. Zeits. f. angew. Chem. 1890, 357—358.

IN the southern part of the Department of Allier, France, granite, the felspar of which has been decomposed, to a depth of about 35 metres, by atmospheric influences, into silicic acid, alkaline silicates and aluminum silicate (kaolin), is so treated with running water that, by suitable regulation of the flow of the latter, fine quartz sand, mica, &c. are first separated, the water containing the suspended "kaolin" passing afterwards into vessels in which the pure clay is deposited. The water is drained off from the deposited kaolin, which is transferred in a moist state to another vessel, in which it is removed to the drying chamber. The dried kaolin is chiefly used in porcelain, crockery-ware,

ultramarine and paper factories. When it is required for paper manufacture, a little methylene blue, or the like, is added in aqueous solution to the water in the settling tanks. —E. G. C.

*On the Composition of Kaolin Porcelains.* G. Vogt. Bull. Soc. Chim. (3), 4, 343—350.

THE analysis of the Chinese porcelains yields results which have been assumed to prove that their composition is about as follows: Kaolin, 50 per cent.; felspar, 30 per cent.; and quartz, 20 per cent. The author, by treating with sulphuric acid some of the actual raw materials as used in China, has extracted a soluble portion which agrees in the amount of its components practically exactly with white mica, both containing about 45·5 per cent. of silica, 37·5 per cent. of alumina, and 6·0 per cent. of water of combination, together with potash and soda. In France it was also believed that pegmatite is analogous in composition to the Chinese minerals yeon-ko and petun; but in reality, as seen in the subjoined table, this is far from being the case:—

	Yeon-Ko.	Pegmatite.
	Per Cent.	Per Cent.
Quartz .....	52·9	23·9
White mica .....	31·3	..
Potash felspar .....	..	72·8
Soda felspar .....	13·4	
Calcium carbonate .....	2·0	..
Soluble silica .....	1·0	..
Soluble matter not estimated ....	..	3·3

In all the different materials used, conclusive proof has been found of the presence of mica. This is in a state of exceedingly fine division, but it can be recognised both by analysis and by microscopic examination with polarised light. A comparison of the imperial porcelain of China with that made at Sèvres reveals the great difference between the two manufactories:—

	China.	Sèvres.
	Per Cent.	Per Cent.
Kaolin (2 SiO <sub>2</sub> , Al <sub>2</sub> O <sub>3</sub> , 2 H <sub>2</sub> O) ....	23·4	35·6
Mica (6 SiO <sub>2</sub> , 3 Al <sub>2</sub> O <sub>3</sub> , K <sub>2</sub> O, 2 H <sub>2</sub> O) ..	23·4	..
Soda felspar .....	25·0	38·0 with potash felspar.
Quartz .....	28·2	26·4
	100·0	100·0

A mixture was made of—

	Parts.
Pure kaolin .....	25
Mica .....	25
Orthose .....	25
Quartz .....	25

which gave a fine, beautifully transparent porcelain. It will be noticed that these are substantially the proportions taken in the Oriental porcelain. It appears to be difficult to find in France materials sufficiently rich in pure mica for use on a large scale.—S. G. R.

*The Kaolin in Blandford, Massachusetts.* W. O. Crosby.  
Technology Quarterly, 3, 228—237.

THIS paper is a description of the kaolin beds of Blandford, which have only within the past year been sufficiently opened up to allow of an examination of the geological surroundings and the formation of an opinion as to the origin of the deposits. The geological situation is described in detail, and from a consideration of it the kaolin has apparently been derived from large veins of a coarse pegmatite or endogenous granite, containing little mica, and consisting chiefly of felspar. It is clearly the product of decomposition *in situ* in pre-glacial times—a genuine remnant of an ancient sedentary soil, which has escaped the erosive action of the great ice-sheet. The following is an analysis:—

	Per Cent.
Silica .....	52.03
Alumina .....	31.76
Water .....	15.55
Magnesia .....	0.54
Oxide of iron .....	Trace.
Lime .....	Trace.
Alkalis (K <sub>2</sub> O and Na <sub>2</sub> O) .....	Trace.
	99.88

The kaolin shows throughout the structural features of pegmatite, and contains undisturbed groups of crystals, half-decayed mica crystals, small grains and fragments of semi-decomposed felspar, and scattered crystals of tourmaline. The last-named are sometimes a foot in length, and although rotted to a coarse black earth, are still essentially intact in form. All these facts tend to disprove the possibility of the kaolin having been washed into its present position. The author then proceeds to give his reasons for considering this a pre-glacial sedentary soil, such soils being known to exist elsewhere in New England.—A. W.

#### PATENT.

*Improvements in the Manufacture of Fire-clay Pipes called "Swan-Necks."* A. Griffiths, Bonnybridge. Eng. Pat. 20,372, December 21, 1889. 6d.

LENGTHS of clay tube partially formed in an ordinary machine, and while still moist, are introduced into a horizontally disposed flask or box of circular section made in two superposed and detachable semi-cylindrical halves. A tubular die is advanced from each end of the flask by tubular screws to form the pipe ends, and a ram or plunger passed through the dies and screws forms the interior of the pipe. A plate fixed to the bottom of the flask with an attached handle serves to remove the completed pipe.

—S. B. A. A.

### X.—METALLURGY.

*The Dry Assay of Tin Ores.* Part II. H. O. Hofman.  
Technology Quarterly, 3, 261—280.

See under XXIII., page 1154.

*Aluminium Steel.* R. A. Hadfield, Sheffield. Meeting Iron and Steel Inst., U.S. America, October 3, 1890.

HAVING mentioned the principal methods of producing the metal itself, reference may be made to the already large employment of aluminium alloyed with copper, known as aluminium-bronzes, for quite a countless number of purposes. It may be interesting here to state, as one of the first public notices, that in the "Morning Star" of May 21, 1862, considerable reference was made to the probability of aluminium-bronze coming into extensive use. The many good qualities of these alloys will no doubt make the use of aluminium in

this direction alone of very wide importance. The following table gives the range of tensile strength and density of these forged aluminium-bronzes:—

#### TESTS OF ALUMINIUM BRONZES.

(By John H. J. Dagger, in a Paper read before the British Association, 1889.)

		Tensile Strength in Tons per Square Inch.	Elongation.	Density.
			Per Cent.	
Aluminium-bronze.	11 % Al. ...	49 to 45	8	7.23
	10 " ...	33 " 40	14	7.69
	7½ " ...	25 " 30	40	8.00
	5-5½ " ...	15 " 13	40	8.37
	2½ " ...	13 " 15	50	8.69
	1½ " ...	11 " 13	55	"

The brittleness of alloys above 11 per cent. prevents their use. Those containing 60 per cent. to 70 per cent. aluminium are very brittle and beautifully crystalline; with 50 per cent. the alloy is quite soft, but under 30 per cent. the hardness returns. The 20 per cent. bronze has a whitish-yellow tint, somewhat resembling bismuth, but is very brittle, and can be pulverised in a mortar. One of the most valuable properties of the alloys given in the above table is that of being forgeable and capable of being worked at a red heat. Table B, having been specially prepared by Professor Tetmayer, of the Polytechnic School, Zurich, for the Aluminium-Industrie Actien Gesellschaft, at Neuhausen, is given for comparison with the foregoing:—

	Aluminium.	Tensile Strength in Tons per Square Inch.	Elongation.
	Per Cent.		Per Cent.
Aluminium-bronze.	11.50	52	0.50
	11.00	44	1.00
	10.00	42	11.00
	9.50	49	19.00
	9.00	37	32.00
	8.50	33	52.50
Aluminium-brass ...	5.50	28	64.00
	4.00	45	6.50
	3.00	33	7.50
	2.50	34	20.00
	2.00	31	30.00
	1.50	29	39.00
	1.00	26	50.00

Professor Tetmayer has plotted his results, the curve obtained showing that with increasing aluminium content the tensile strength increases slowly at first, but then grows rapidly as the alloy is made richer in the lighter metal.

*Alloys of Cast Iron and Aluminium.*—As with other cast iron, aluminium cast iron, if it may be so termed, naturally comes under a different classification to that of the malleable compounds of aluminium and iron. Keep found that aluminium has, in a considerable degree, a similar influence to that of silicon upon cast iron, a fact strikingly confirmed in some special experiments of the writer relative to the action of aluminium upon combined carbon in spiegeleisen, and

described later on. It is, however, only proposed to deal here with aluminium in its use in the manufacture of steel or steady compounds. There appears to be much misconception as to whether its employment is productive of good, and the author confesses that he believes that whilst the price remains so high, and except in certain special cases, its application does not seem likely to become large. Aluminium appears to be of most service as an addition to baths of molten iron or steel unduly saturated with oxides, and this in properly regulated steel manufacture should not often occur. Speaking generally, its rôle appears to be similar to that of silicon, though acting more powerfully. It must, however, be remembered that these experiments have been made with practically pure aluminium. If pure silicon were also obtainable, its effect would probably be found to be almost the same. So long, therefore, as ferro-silicon varying in silicon from 8 to 20 per cent., can be obtained at from 3*l.* 10*s.* to 10*l.* per ton, as compared with aluminium or ferro-aluminium of like percentages costing 112*l.* to 250*l.* per ton, it will be seen that the probable field of usefulness for the latter must be much circumscribed.

#### CAST ALUMINIUM STEEL.

**Melting.**—The material obtained for these experiments was produced by melting in crucibles, in the ordinary manner, good wrought bar iron, and adding the aluminium (about 98 per cent. of aluminium), manufactured by the Pittsburgh Reduction Company's system, shortly before "teeming." Although a difficult one, the object was to obtain an alloy or compound consisting as nearly as possible of aluminium and iron alone. In the material made it will be found that the other elements present do not amount to more than 50 per cent., so that this intent may fairly claim to have been accomplished. The ingots, 2½ in. square, were reduced by forging in the ordinary manner to bars 1½ in. diameter. The consideration of the qualities of these alloys is divided into two heads: first, the material in the cast; second, the material in the forged state.

**Cast State.**—Nothing special was noted during the melting operations, but in all cases upon adding the aluminium "coruscation" was observed. This evolution of heat and light has also been observed when alloying aluminium with copper. Does not this tend to indicate that aluminium added to iron produces true compounds and not merely alloys, as it is well known in laboratory operations that the evolution of heat during the mixture of two substances is often a sign of chemical union? The curious properties of manganese steel seem especially to prove that such a material is a true compound, and no doubt aluminium steel may be classed under the same head.

**Fluidity.**—It is doubtful whether aluminium increases the fluidity of properly made steel, but if it does, the apparent increase or evolution of heat just referred to seems to the author far more likely to account for any increase of fluidity that may occur rather than the so-called lowering of the melting point. As the aluminium increases to large amounts over about 0.50 per cent., the metal becomes quite thick, "creamy," and sets quickly. No doubt this is partly caused by a considerable portion of the aluminium being oxidised to alumina and becoming entangled as slag, in the same way as occurs when silicon is oxidised to silica. Unless suitable flux is present, this excess of oxide cannot be carried off, the molten metal becomes less fluid, and causes the "thickness" noticed. There is a resemblance in this respect to the action of high percentages of silicon added to iron. When exceeding about 0.75 per cent. of aluminium the molten material so rapidly "creams" over on the surface, that the production of sand-moulded articles is only effected with difficulty—in fact, it was only by using considerable care that the cast test bars were obtained. (Keep, even with cast iron, found a decided decrease in fluidity by the addition of aluminium.) It must not be overlooked that the author is here referring to comparatively high percentages. So far as his own experiments have gone, aluminium, as regards lower percentages, also acts in a similar manner to silicon under the same circumstances.

So much has been said as to aluminium lowering the melting point of iron that the author wonders how and why this statement was originated, as it certainly seems to have no foundation in fact. This is confirmed by Osmond, who by means of the "Le Chatelier" pyrometer (this Journal, 1890, 326) kindly made for the author a special determination as to the melting point of an alloy containing 5 per cent. Al and about 94½ per cent. Fe. The sample in question did not show the slightest signs of fusion until a temperature of 1,475° C. was reached. As mild steel by the same pyrometer was shown to fuse at about 1,500° C., there could therefore have been little or no lowering of the fusion point; and if this is the case with an alloy containing 5 per cent., still less can it be so with one containing only 10 per cent., which is the quantity usually described as being present when the so-called lowering point is supposed to occur. It is especially satisfactory to have the testimony, not only of Osmond (this Journal, 1890, 517 and 865), but that of H. M. Howe (this Journal, 1890, 946), who both agree with the author on this point. In the author's opinion, if any increase of heat or fluidity takes place by the addition of small amounts of aluminium, it may be due to either of the following causes, or to both combined. First, there may be evolution of heat owing to oxidation of the aluminium, as the calorific value of this metal is very high—in fact, higher than silicon. According to Berthollet, the conversion of aluminium to  $Al_2O_3$  equals 7,900 cals., silicon to  $SiO_2$  is stated as 7,800. This oxidation is probable, as in the writer's experiments the addition of aluminium to iron was always accompanied by more or less, often considerable, loss of the former metal. This is also proved by the fact of its appearing in the oxidised state in a white powder upon the side of the ingot mould, as well as in the slag; also from the fact that when small amounts are added they are rarely found in the product when being analysed. In the 5 per cent. specimens previously referred to, the author found no less than 2 per cent. was wasted. Against the supposition that by oxidation increase of heat is obtained must, however be placed the fact that when the aluminium exceeds, say, about 75 per cent., the less fluid is the product and the more metal is wasted; but at the same time the explanation first offered might still hold good as regards the lower percentages, say under 50 per cent. Secondly, and more probably, the correct explanation. As proved by Galbraith, the fluidity of molten iron and steel depends not only upon the amount of heat imparted by external means or by oxidation, but often upon the quantity of intermingled slag or oxide of iron (this Journal, 1890, 864—865). He found that in certain cases in excessively over-oxidised steel, although the heat of the furnace was more than usual, the product was still lacking in fluidity. It would be interesting to have the point followed up and thoroughly tested by means of the "Le Chatelier" pyrometer. As supporting this, it may be observed that the well-known German metallurgist, Ledebur, believes the rôle of aluminium "to be no other than that of destroying the dissolved oxide of iron present." That such over-oxidised metal possesses different properties as compared with ordinary steel or iron is very clear, for the author has had brought under his notice certain cases of over-oxidised iron which continued to rise, give off gases, and prove unsound in the ingots, notwithstanding the addition of even considerable quantities of aluminium. They are, of course, exceptional, and to the author seem to be explained by the facts pointed out by Galbraith. The loss of the metal in melting is variable, but in nearly all cases amounts to a considerable proportion of the percentage added.

The experiments prove that more aluminium may be present in the cast material than silicon in cast silicon steel before brittleness sets in. After reaching the region of brittleness, and by adding still higher percentages of aluminium, there is no return of strength, on the contrary; so that this material in no way resembles the curious property noted in this respect with regard to manganese steel.

**Bending Tests.**—The annealed samples up to 85 per cent. bent double cold; those unannealed were not so good. The gradual increase of aluminium is very clearly shown to

reduce the toughness both of the unannealed and annealed specimens. They were sound with the exception of two samples, but not more so than cast silicon steel of corresponding percentages.

**Hardness.**—As might be expected from the soft nature of the metal aluminium, its addition to iron does not add materially to the hardness, again in this respect resembling the effect of silicon. Seven to 8 per cent. cast aluminium steel may be readily drilled and filed. Neither does its addition, unlike manganese, interfere with the magnetic susceptibility of the iron present.

**Appearance of Fracture.**—Aluminium in the cast specimens opens the grain, *i.e.*, increases the size and coarseness of the crystals, and as the higher percentages are reached it is somewhat difficult to distinguish the fractures from those of cast silicon steel. The crystals in the 5 per cent. and upwards specimens become very large and cleave somewhat after the nature of spiegelstein. This accounts for the increasing brittleness of the cast material, and neither the fracture nor the brittleness accompanying it in such samples can be changed by annealing.

#### FORGED ALUMINIUM STEEL.

**Malleability.**—As high as 5.60 per cent. aluminium may be present before malleability ceases. This is about the same limit as in the silicon steel described by the writer. It may be pointed out, as regards the specimens under discussion, that they are very low in manganese. Notwithstanding this, the malleability is satisfactory.

**Mechanical Properties, &c.**—Up to 2.24 per cent. aluminium the annealed samples bent double cold, but upon reaching 5 per cent. a great diminution of strength took place, and annealing practically produces no effect.

One difference clearly brought out is, that the tensile strength of iron is not increased so much by an addition of aluminium as of silicon. It has been stated that very small percentages of aluminium considerably raise the limit of elasticity. It will be seen from the table of tests, and specially from the two almost carbonless samples just quoted, that this increase is slight, if any, as compared with ordinary steel, and also that aluminium does not raise the elastic limit so much as silicon. Seeing that aluminium is an exceptionally soft and malleable metal, possessing a tensile strength of 8 to 10 tons, it is hardly to be expected that this should have been otherwise, and it is a pity that such incorrect statements as above mentioned are started, without foundation in fact. The elastic limit of samples should always be determined on annealed specimens, as by cold forging or rolling, the elastic limit of even mild steel can be readily raised several tons per sq. in.; and it would hardly be correct to call this the normal permanent set of the sample under examination. Aluminium and silicon, therefore, stiffen iron but little, whilst carbon, chromium, tungsten, manganese, and nickel clearly increase rigidity; and this, from their nature and hardness, might be expected.

**Hardness.**—As might be expected from the soft nature of the metal aluminium, its addition to iron does not confer appreciable hardness when in either the forged or cast state. In this respect also it resembles silicon steel. The forged material containing 5 per cent. is very soft and easily drilled or filed. The action of aluminium may therefore be classed along with that of silicon, sulphur, phosphorus, arsenic, and copper, as giving no increase of hardness to iron, in contra-distinction to carbon, manganese, chromium, tungsten, and nickel. Water quenching upon either forged or cast aluminium steel (in which carbon is practically absent) seems to produce no effect, the samples when dipped at even a welding heat being almost unchanged. It has been stated that the influence of aluminium on high carbon or tool steel is to destroy its hardening action. This is quite incorrect; the writer has prepared steel containing  $1\frac{1}{2}$  per cent. aluminium and 1 per cent. of carbon, which hardens sufficiently to scratch glass. Here again we have another addition to the lists of elements which, alloyed with iron, do not produce "water-quenched hardness," if the term may be allowed. In fact, notwithstanding that

manganese, chromium, tungsten, and nickel do impart a certain and considerable kind of hardness to iron, either in the cast or forged state, carbon retains its position as being the only element which confers upon iron the property of becoming hard by water-quenching. In steel made with the hard metals just mentioned, if the carbon present be low, no matter at what heat they are water-quenched, the characteristic hardness of carbon steel, such as scratching glass or forming the edge of a cutting tool, is wanting.

**Fracture.**—Aluminium causes the tough percentages, both in the cast and forged material, to break with dark fibrous fracture, similar to wrought iron of good quality, only much darker in colour. In several of the tested tensile specimens a rough and ribbed surface is noticed, proving looseness of texture.

**Weldability.**—Samples with .61 per cent. of Al, .72 per cent. of Al, and 2.20 per cent. of Al were tested for welding, but unsuccessfully. It would be interesting to try electric welding. The writer has always found that these special steels or alloys, such as silicon, manganese, or chromium steel, have slight, if any, welding properties.

**Application.**—If aluminium can eventually be brought to compete in price with existing alloys, there is a probability of something being done in introducing its use on a larger scale. Aluminium may find a use for certain special purposes, such as in higher carbon steel, where silicon does not seem to act so powerfully in producing soundness as in the case of milder steel with carbon .50 per cent. and under. Its special advantage seems to be that it combines in itself the advantages of both silicon and manganese; but so long as alloys containing these metals are so cheap, and aluminium dear, its extensive use seems hardly probable.

**Points of Resemblance between Aluminium and Silicon Steel.**—Osmond wrote to the author as follows:—"In 1833 I made some aluminium steel, and found its tensile strength and elongation were modified almost exactly as by the same proportions of silicon. Second, aluminium, like silicon, causes a precipitation of graphite in cast iron. Third, the cooling curve of the aluminium alloy is nearly the same as that of the 4.50 per cent. silicon alloy. Fourth, aluminium and silicon have almost the same atomic volume."

**Effect of Aluminium upon Manganese Steel and Spiegelstein.**—Believing that aluminium, like silicon, would cause a precipitation of graphite, the writer added between 3 and 4 per cent. to ordinary spiegel (12 and 25 per cent. of manganese). The result in both cases was a complete change from the well-known spiegel fracture to that of ordinary close No. 3 grey pig iron. Although there has been this great attraction in the form of the carbon, no change in the non-magnetic properties of the iron was apparent. This experiment, therefore, clearly proves that the neutralisation of the special magnetic qualities ordinarily possessed by iron is in manganese compounds quite independent of the particular state or form in which the carbon present exists.

**On the Removal of Silver by Means of Zinc.** H. Rössler and B. Edelmann. *Berg. und Hütten. Zeit.* 49, 245.

LEAD and zinc are increasingly soluble in one another as the temperature rises, as the following table shows:—

Temperature.	Zinc contained in the Lead.	Lead contained in the Zinc.
	Per Cent.	Per Cent.
400° (melting point of zinc) .....	0.6–0.8	1.7
500° .....	0.9–1.3	2.3
600° (melting point of aluminium) .....	1.5–2.3	3.5
700° (bright red heat) .....	Over 3.0	5.6

When a considerable excess of zinc is present, it rises to the top, carrying with it the silver from the lead. In working

on the large scale a large amount of zinc is undesirable, but under these conditions it is difficult to avoid loss by oxidation, and by the formation of a scum containing more lead than zinc. To prevent this loss it is advisable to cover the mass with a layer of melted sodium potassium chloride, which also assists the separation of the metals. By this method alloys can be produced containing 1 part of silver to 3 of zinc.

Further experiments, on removing the zinc from the lead by the action of indifferent gases, such as carbonic acid, either alone or mixed with nitrogen, or carbonic oxide with nitrogen and hydrogen, proved completely successful, especially if the gases be employed hot, and the temperature of the metal be kept as high as 700°. (See also this Journal, 1890, 77.)—F. H. L.

#### PATENTS.

*Improvements in the Treatment of Copper or Cupreous Compounds for the Production of Sulphate of Copper and the Extraction of the Precious Metals, and in Apparatus applicable therefor.* T. Haeghe, Briton Ferry, and "The Cape Copper Company, Limited," London. Eng. Pat. 18,297, November 15, 1889. 8d.

COPPER in leaf or granular form, or in shots, is charged into a lead-lined tub provided with a perforated lead false bottom supported on bricks or other material which can resist the action of hot sulphuric acid. The tub is covered with a perforated lead tray on which is poured a continuous stream of hot dilute sulphuric acid which gradually percolates through the metal. Air or steam is injected by a blast pipe placed immediately under the false bottom, and the acid liquors are drawn off by an exit pipe lower down. The action of the descending acid and ascending steam and hot air effects the rapid dissolution of the copper; the hot concentrated solution of copper sulphate which flows out from the lower pipe is crystallised in troughs, and the mother-liquor strengthened with acid and used again.

Any gold or silver contained in the copper is left in the metallic condition at the bottom of the tubs and troughs.

—S. B. A. A.

*Improvements in the Manufacture of Metallic Alloys and Compounds and in Apparatus therefor.* J. C. Bull, Belvedere. Eng. Pat. 19,148, November 28, 1889. 4d.

THE author prepares copper and tin phosphides "without loss of phosphorus" by passing phosphorus vapour into the molten metals. The phosphorus is volatilised in a cast-iron retort similar to that used for the distillation of mercury, but fitted with a valved iron tube at the further end of which there is a bend and a vertical end-piece of fireclay or carbon, and with a spring safety valve and tube for escaping vapours. The retort is at first filled with carbonic anhydride, and is heated steadily to a red heat. When a saturated alloy of a metal with phosphorus is required, the vapours are led into the metallic bath until they begin to burn on the surface. To prepare other compounds the retort and tube are counterpoised before starting, and the diminution of the weight observed from time to time, the retort being prevented from moving more than a fraction of an inch. Other volatile substances, as sodium, potassium and mercury, may be treated in the same manner.—S. B. A. A.

*Improvements in the Method of and Converters or Machinery for the Manufacture of Iron or Steel.* W. Sellar, Sunderland. Eng. Pat. 19,333, December 2, 1889. 8d.

THE molten metal is run into a square or cylindrical converter mounted on hollow trunnions and provided with a convex hearth, to which an oscillating motion is imparted by suitable mechanism. Air or a mixture of air and gas is injected through the hollow trunnions into the converter above the level of the metal, and at the close of the reaction the metal is made perfectly fluid by increasing the supply of gas and air in proper proportions. The oscillation of the converter is continued for some time after the stoppage of

the gas supply, in order to release the gases absorbed by the metal. The metal is then either run out through a tap-hole in the malleable condition or it is converted into steel by the addition of carbon. It is claimed that the passage of the metal in a thin layer over the convex surface of the hearth greatly facilitates the oxidation of the impurities and the expulsion of absorbed gases.—S. B. A. A.

*Improvements in and connected with the Extraction or Reduction of Zinc from Ores or Compounds.* C. Rabache, Morechain, France. Eng. Pat. 19,501, December 4, 1889. 1s. 1d.

THE distinguishing features of this process are the preliminary "releasing of the metallic part of the ore from its gangue by the vaporisation of the water of combination," and the smelting and reduction of the ore by pure carbon monoxide in the absence of atmospheric air. The ore is sorted, crushed to a granular powder 1 to 3 mm. in diameter, and heated for a short time to a temperature of 200°–400° C., by the combustion of carbon monoxide, with continuous shaking. The latter operation effects "the expulsion of the water of crystallisation, sulphur, and other volatile impurities, and the separation of the metallic particles from the gangue;" the ore is then concentrated with or without previous sizing, and the pure zinc oxide powder obtained in this way introduced in a continuous stream into a furnace of special construction (see Eng. Pat. 11,851 of 1890, next page) previously heated to a minimum temperature of 2,730° F. by the combustion of carbon monoxide in air. The air supply is then stopped and carbon monoxide alone introduced when "the falling ore is enveloped by the gas and a flameless combustion of the carbon monoxide gas in the oxygen of the ore ensues, resulting in the reduction of the metal, which falls in a molten state on the floor of the smelting furnace, and is removed by suitable means."

—S. B. A. A.

*Improvements in Cleaning Sheets of Wrought Iron, Iron Wire, and Articles of Wrought Iron, and in utilising the Waste Products obtained, and in Apparatus to be employed in conducting the said Cleaning and Utilising Processes.* E. P. Peyton, Birmingham. Eng. Pat. 19,865, December 10, 1889. 8d.

WROUGHT iron plates are pickled in hot dilute sulphuric acid in the ordinary way, commercial oil of vitriol diluted with 10 vols. of water being preferably used at a temperature of 200° F. The improvement consists in allowing the contents of the pickling tank when sufficiently concentrated to flow slowly through a long cooling channel and there deposit the greater part of the dissolved sulphate of iron, the mother-liquor passing into a vessel from which it is continually pumped back into the pickling tank, vitriol and water being added till it is of the proper strength. The process is continuous after being fairly started. Cylindrical pickling tanks are used for cleaning wire.—S. B. A. A.

*Improvements in the Manufacture of Steel or Ingot Iron.* J. H. Darby, Brymbo. Eng. Pat. 20,586, December 21, 1889. 6d.

THE method previously described in Eng. Pat. 418 of 1888 (see also this Journal, 1889, 546 and 549), which consists in running metal from the ladle through a vessel containing carbon into a supplementary casting ladle has the disadvantage of requiring an arrangement of the converter and appliances for casting, absent in many works. The following is an alternative process. The coke or other carbonising material is finely ground and placed in a hopper carried on the ladle crane and communicating with a worm or spiral or with the cavities of a wheel the movement of which discharges a regulated quantity of the carbon down a spout into a small vessel placed between the ladle and the ingot mould. In this vessel the current of metal from the

ladle meets and thoroughly mixes with the carbon, afterwards passing through an opening in the bottom into the ingot mould. The steel produced by this method will stand quiet in the moulds so that the addition of ferro-silicon is unnecessary, whilst the amount of carbon in the same may be arrived at with great certainty. Spiegel or ferro-manganese may be first added to the metal if desired.—S. B. A. A.

*Improvements in Apparatus for Treating Finely-divided Metalliferous Material for the Purposes of Separation and Amalgamation.* W. L. Wise, London. From J. B. Walker, Corvallis, Oregon, U.S.A. Eng. Pat. 20,677, December 23, 1889. 11d.

THE author proposes "to disintegrate the pulp so as to separate each particle of precious metal from the sand and to introduce the pulp particle by particle into the lower part of a mass of mercury." This is effected by means of an apparatus consisting essentially of a drum or pan containing (1) a central shaft; (2) a low pedestal continued into a tube enclosing a portion of the shaft; (3) a disintegrating feed-wheel consisting of a tubular portion secured to the upper free portion of the shaft and continued into a disc overlying the pedestal and containing peripherally inclined and covered flutings or passage ways with centrally raised walls and inwardly facing cutting edges; (4) an annular water reservoir with perforated outer wall surmounting the feed-wheel, the space between its inner tubular wall and the tubular part of the feed-wheel forming a feed chamber; (5) the mercury chamber, consisting of the annular space between the pan casing and the reservoir and pedestal; (6) an annular discharge trough attached to the exterior of the pan; (7) an agitator consisting of three series of concentric floats, one set being fixed to the wall of the reservoir, another set oscillating over the surface of the mercury, and the third set moving in the trough.

The pulp falling from the feed chamber is thoroughly disintegrated by the sharp edges of the walls of the flutes in the discoid part of the feed-wheel, and the particles are separately forced (by the centrifugal force due to the rotating feed-wheel) through the flutes past suitable valves into the mercury surrounding the pedestal by which the gold and silver are retained. The sand rises to the surface of the mercury, where it is met by the flow of water from the reservoir, and is swept away by the agitators into the trough. For details of the valves, feed motion, &c., the drawings in the specification must be consulted.—S. B. A. A.

*Improvements in Apparatus for the Extraction or Reduction of Zinc and other Metals from Ores or Compounds.* C. Rabache, Morchain, France. Eng. Pat. 11,851, July 29, 1890. 11d.

THE apparatus are adapted to the method described in Eng. Pat. 19,501 of 1889 (previous page), and consist of:—(1) a "rotatable" drum fitted with a sand-luted cover and with slanting internal ledges for shaking up the contents, and provided with suitable openings for charging and discharging the ore, and with perforated pipes for introducing carbon monoxide; (2) a small horizontal hermetically-closed smelting furnace terminating in a vertical gorge or gullet and having in the centre a syphon serving as a free and constantly opened outlet for the fused metal.

Claims are also made for a new sizing machine composed of concentric revolving cylindrical screens; for two forms of concentrators or "densimetric separators;" for an apparatus for producing carbonic anhydride from limestone; for an apparatus consisting of a series of enclosed upright retorts for converting the carbonic anhydride into carbon monoxide; and, lastly, for a floating compensating valveless gas holder for storing the carbon monoxide, and for a gas exhaustor and regulator. Four sheets of drawings are appended.

—S. B. A. A.

*Improved Process of and Means for the Separation of Tin from other Metals, more particularly from Scrap Tinplate and used Preserve Tins.* A. A. F. Bang and M. C. A. Ruffin, Paris, France. Eng. Pat. 12,553, August 11, 1890. 8d.

IN Eng. Pat. 70 of 1890 (this Journal, 1890, 950) it was proposed to strip tinplate by means of soda lye and nitrate of soda or other oxidising agent. According to the present specification atmospheric air is used in lieu of nitrate of soda. The scrap may either be placed in a deep tank and treated with soda or potash lye of 15° to 20° B. at a temperature of about 60° C., air being injected at the bottom of the tank, or the use of compressed air may be avoided by loosely piling the scrap in a deep cylindrical vessel carried on lateral trunnions and closed on both sides by movable gratings. A pipe connected by a pump with the lye tank terminates over the cylinder in a wide rose which distributes the heated lye over the metal, while the liquor after percolating through the cylinder falls into a trough placed underneath, and is thence returned to the lye tank. The heat of the metal and lye produce a strong upward air current through the cylinder, and the intimate contact of the air, lye and metal promotes rapid oxidation and solution of the tin. The cylinder is occasionally reversed to ensure a uniform action. Large quantities of scrap may be treated in a stationary cylinder provided with a central longitudinal perforated tube closed at one end and connected with a fan at the other. The stanniferous lyes are preferably decomposed with carbonate of lime, the lyes being passed over until the deposit consists almost entirely of calcium stannate.—S. B. A. A.

*An Improved Process and Means for Producing the Generation of Chlorine Gas for the Chlorination of Gold or other Ores.* C. T. J. Vautin, London. Eng. Pat. 12,641, August 12, 1890. 4d.

THE chlorine is generated from a mixture of about equal weights of bleaching powder and perchloride of iron or manganese, together with about 5 per cent. of water. The reaction is represented by the equation—

The materials are charged into a vessel containing the ore to be acted upon, and the vessel is preferably closed during the generation of the gas. One of the advantages is the use of materials which may be transported with perfect safety.

—H. S. P.

*Improvements in Apparatus for the Extraction of Gold.* C. T. J. Vautin, London. Eng. Pat. 13,259, August 22, 1890. 6d.

THE author employs an air-tight combined dissolving and leaching barrel, carried on hollow trunnions and fitted in the interior with oblique baffles or part diaphragms for mixing the ore and reagents, and at one end with a filter bed so secured that the filtering medium is not displaced on rotating the barrel. The gold-bearing solution is either drawn through the filter bed by a diaphragm pump, or it is forced out by admitting water under pressure at the top of the leaching-barrel. The water supply and solution exit pipes pass through the trunnions. Drawings of the new barrel and pump and of a complete gold-extraction plant with a novel arrangement of depositing vessels, are attached to the specification.—S. B. A. A.

*The Manufacture and Production of a Dissolving and Reducing Agent, and the Employment of the same in Coating Metals with Metals or Combinations with Metalloids, Extracting Metals from their Ores or Combinations and in other Arts and Manufactures in which Dissolving or Reducing Action is required.* C. E. Bernard, Beaumont, France. Eng. Pat. 14,837, September 19, 1890. 6d.

THE "dissolving and reducing agent" is prepared by saturating glycerol with bromine at a temperature not

exceeding 80° C. and preferably about 60° C. It may be used for obtaining a metallic deposit upon a more readily oxidisable metal. Thus, for example, zinc may be coated with aluminium by first saturating the above compound at 100° C. with aluminium oxide added in small quantities at a time. The clear well-settled solution is then painted upon the perfectly clean zinc article or the latter may be immersed in the solution, when a brilliant white deposit is at once produced, which can be rubbed and polished with a leather. Or the article to be coated can be plunged into an electroplating vat containing the new compound with the further addition of a little sodium bisulphite and caustic soda when, upon passing an electric current, an immediate deposition of the metal is effected. Thus lithium, cobalt, "carbon," &c. can be thrown down. The compound is said to be also capable of "dissolving or reducing silica, spar, asbestos, tale, arsenic, phosphorus, cotton, wool, silk, cellulose, &c." —S. G. R.

*Improvements in Method and Apparatus for Producing Mineral Wool.* W. H. Kennedy, Etna, Penn., U.S.A. Eng. Pat. 14,846, September 19, 1890. 8d.

See under 1., page 1116.

## XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

### PATENTS.

*Improvements in the Manufacture of Electrodes or Plates for Electrical Batteries.* P. Schoop. Eng. Pat. 15,963, October 10, 1889. 6d.

THE plates are formed by the simultaneous electrolytic deposition of spongy lead, containing hydrogen, on one plate, and oxide of lead, or oxidised lead in combination with an alkali, on the other. The electrolyte used may be a lead salt with a suitable alkaline salt—e.g., 1 part of lead sulphate, 1 part of nitrate of ammonium, 10 parts of water—or an organic lead salt combined with an inorganic one, with or without an alkali. The organic salt may be the tartrate, sulphonate, &c., or that formed by adding glycerin to concentrated sulphuric acid, diluting and adding a lead base.—E. T.

*Improved Process of Purifying the Anhydrous Double Chloride Compounds of Aluminium.* H. Y. Castner, London. Eng. Pat. 18,062, November 12, 1889. 8d.

THE anhydrous compound, containing ferric and ferrous chlorides as impurities, is melted and caused to flow at a suitable rate through a series of baths containing electrodes. A considerable current is passed between the electrodes in the first bath, less in the second, and so on, the current being proportioned to the quantity of impurity still left. By this plan the iron alone is deposited on the cathodes without waste of aluminium.—E. T.

*Process for obtaining Chlorine and Bromine by the Aid of Electricity.* G. Nalmsen, Hanover, Germany. Eng. Pat. 11,699, July 26, 1890. 4d.

WHEN chlorine or bromine are obtained by electrolysis waste usually goes on by the reaction of these bodies on the water of the electrolyte. To prevent this the patentee cools the solutions below 0° C. by the aid of refrigerating machinery, taking precautions that the solutions shall be kept highly concentrated, current not below 0.25 amp. per sq.

decimetre, and the voltage 25 to 30 per cent. above that theoretically calculated. Chlorine so obtained is quite dry and free from hydrochloric acid.—E. T.

*Improvements in Galvanic Batteries.* H. J. Allison, London. Eng. Pat. 13,344, August 25, 1890. 8d.

A CHLORIDE of silver cell is made up, in which the case is of zinc, and forms one electrode. The chloride of silver is cast, with a corrugated or indented surface, round a silver wire to which are attached pieces of silver wire, foil, or gauze to make more intimate contact with the chloride. The electrolyte is rendered viscous by the addition of a suitable albuminous or gelatinous material. The silver wire projecting above the chloride of silver is covered with close-fitting india-rubber tubing. The cell is closed by Portland cement or other material which is porous to gas, but will not allow the viscous electrolyte to pass. Such cells are made very small and may even be put into a push or ordinary fitting.—E. T.

## XII.—FATS, OILS, AND SOAP MANUFACTURE.

*Tar Soaps and "Lysol," a New Disinfectant.* C. Engler. Dingl. Polyt. J. 278, 26—34 and 78—83; Pharm. Centralhalle, 1890, 449.

DISINFECTANTS which are prepared from soap and coal-tar oils may be divided into two classes: 1st, those that are solutions of soap in hydrocarbons; and 2nd, those that are solutions of hydrocarbons or phenols in soap. When petroleum oil (b.p. 150°–250°) is heated with a mixture of oleic acid and the oxides or hydrates of various metals, considerable quantities of soap are found to be dissolved in the oil, the maximum occurring in the case of lead, 15.5 per cent. of PbO being found in the liquid. To this first category belong most of the so-called "solidified oils," which are generally aluminium, magnesium, or other soaps dissolved in petroleum, and also the disinfectants known as "kreolin," "soluble phenyle," &c. All these solutions have the disadvantage of separating into two layers on the addition of water, only the soap going into the aqueous solution.

To avoid this loss the author has tried to prepare mixtures falling within the second class; the carbolic oils employed consisting (I. and II.) of about 82 per cent. of phenols, and (III.) of about 13 per cent. The alcohol was added to assist the saponification but was found to be unnecessary:—

	A.	B.	C.	D.	E.	F.
Linseed oil.....	30.8	30.8	30.8	..	..	..
Train oil.....	..	..	..	30.8	..	..
Rape oil.....	..	..	..	..	30.8	..
Rosin.....	..	..	..	..	..	33.1
Caustic potash*.....	18.4	18.4	18.4	18.4	18.4	30.5
Alcohol.....	20.0	20.0	20.0	20.0	20.0	23.2
Carbolic oil I.....	30.8	..	..	..	..	..
Carbolic oil II.....	..	30.8	..	30.8	30.8	13.2
Carbolic oil III.....	..	..	30.8	..	..	..

\* One part solid dissolved in two of water.

The solutions obtained were of a brown colour, and on dilution with distilled water gave perfectly clear liquids, C being slightly clouded owing to the impurity of the carbolic

oil employed. On distillation solutions A—E gave off an amount of oil practically identical with the quantity originally added, proving that the phenols exist in the free state. Solution F gave on distillation 17 per cent. of oil, the excess of 3·8 per cent. being probably due to decomposition of the rosin. To prove conclusively that the phenols were not combined, being liberated only on heating, cold solutions of potassium "carbolate" and "cresylate" were treated with oleic acid, when considerable heat was evolved, showing that chemical reaction was taking place.

"Lysol" is a new preparation of Schülke and Mayr's (Hamburg), which evidently is a similar substance. It exists in three forms known as No. II., No. III., and "Pure Lysol," and is a brown, transparent, syrupy liquid, which turns litmus blue, but contains no free alkali. The ash, which was found to be potassium carbonate, amounts to from 5·9 to 6·5 per cent. On distillation up to 225°, 47 to 51 per cent. of oil was obtained, containing about 95 per cent. of higher phenols (carbolic acid itself being absent).

Each of its preparations is miscible with water in all proportions, and hence forms a disinfectant which can be made of any desired strength, without the loss accruing from the insolubility of the active principle. It has also the advantage over phenols rendered soluble by the addition of strong sulphuric acid, in that it exists in a neutral solution, and hence might possibly be of great service against phylloxera, &c.

Schottelius (Münchener Medicinische Wochenschrift, 1890, No. 20) has examined the power that lysol possesses of destroying pathogenic organisms, the bacilli employed being those of cholera, typhus, and swine fever. In the case of the first two, the addition of ·33 per cent. of either lysol II. or III. destroyed in 20 minutes all bacilli, the power of the material over swine-fever being only slightly less. Lysol was next compared with ordinary phenol, and Pearson's kreolin (Jeyes') as to its power of instantly destroying all living germs. For this purpose *Staphylococcus py. aureus* and *Typhus bacillus* were chosen as having very different degrees of vitality, the minimum quantity being shown in the table:—

	Lysol.	Kreolin.	Phenol.
	Per Cent.	Per Cent.	Per Cent.
<i>Staphyloc. p. aureus</i> .....	·3	1·2	2·5
<i>Typhus</i> .....	1·2	..	..

—F. H. L.

*A New Fatty Acid.* E. Gérard. Compt. Rend. **111**, 305—307.

THE oil from the seeds of *Datura stramonium* (thorn apple) contains, according to the present article, a fatty acid which has hitherto remained undiscovered. The seed oil is extracted with ether; the extract is taken to dryness, and purified by dissolving in petroleum ether, filtering and distilling. A greenish-yellow oil is thus obtained. This oil, on saponification with litharge, yields lead soaps, from which the salts of oleic and linoleic acids are extracted by ether; the residual salts are decomposed with hydrochloric acid, and the resulting fatty acids are dried and dissolved in alcohol, from which, by cooling, a mass of crystals may be obtained. The crystals melt at 56°. Of these crystals a cold-saturated alcoholic solution is made and fractionally precipitated with barium acetate. The earlier products yield an acid melting at 55°, the later portions an acid melting at 62° (palmitic acid). The acid melting at 55° is an acid whose composition is stated to agree with the formula  $C_{17}H_{33}O_2$ . Further fractionation with barium acetate gives constant results and no further splitting up of the substance could be recognised. The author proposes the name "daturic acid."

Compounds claiming to have this formula have already previously been described; one by Becker in 1857, melting at 52°; another by Hantz soon afterwards, whose melting

point was put at 60°; and thirdly, one by Krafft in 1879, melting point 60°.

The formula claimed for the new acid places it between stearic and palmitic acids, yet its melting point is considerably lower than that of either of these acids.—T. L. B.

*Report on Soaps.* Report of the Central Laboratory of the Italian Customs Department, 1886—1889. 356—364.

THE tariff distinguishes between common, perfumed, and glycerin soaps, subject to duties of 8, 40 and 60 lire per quintal. In the first class are included every kind of hard soap, and soap containing silicious and earthy matters, as also pasty mixtures of fat, oil, soda and potash, together with cart-grease composed of oils of resin and fatty substances mixed with alkalis. In the second class are included soaps in tablets, &c. and soft soaps, which are not of the nature of so-called silk-soaps, while transparent or semi-transparent soaps, even though not perfumed, are relegated to the third class. Lastly, medicinal soaps such as those of opodeldoo, naphthalene, eucalyptus, iodine, &c., and soaps with lead oxide as their base, are classified as compounded drugs not specified. The Department determined the proportions of water, total alkali, free alkali, and fatty acid saponified, resin, glycerol, alcohol, medicinal substance, and essence or essential oil. Samples of common soap appear to have been declared as calcium chloride, various fats and vegetable fat.—V. H. V.

## PATENTS.

*Improvements in Extracting Oil or Grease.* W. H. Lever, J. D. Lever, and E. G. Scott, Port Sunlight. Eng. Pat. 18,988, November 26, 1889. 4d.

IN the ordinary process of extracting oil or grease from seeds or other materials by means of bisulphide of carbon, the inventors substitute for that solvent the tetrachloride of carbon (this Journal, 1890, 1063), which is said to be less dangerous to use and to leave the extracted oil in a purer condition.—G. H. B.

*Improvements in Soap Powders.* G. P. Clarke, London. Eng. Pat. 13,985, September 5, 1890. 4d.

A NEUTRAL salt of ammonium is incorporated with ordinary soap powder. In order to preserve the salt, preferably the sulphate of ammonium, from being decomposed by the sodium carbonate of the soap powder, the crystals are coated with finely-powdered sugar, and also, if necessary, with some fatty substance. It is only on dissolving the mixture in water that the neutral ammonium salt is decomposed, carbonate of ammonium being formed.

—G. H. B.

## XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

*The Preparation of Ultramarine.* J. Wunder. Chem. Zeit. **14**, 1119—1123.

IN 1840 the manufacture of ultramarine was confined to three works, two in Germany and one in France. Since that date the number of colours has largely increased, including at present light and dark blue, green, red, violet, and white. For the production of ultramarine green and blue (from sodium sulphate), a mixture of kaolin, sodium sulphate, and coal is heated in crucibles to a bright red heat: sodium sulphide is produced which forms with the components of the kaolin a green mass. On treating this with sulphurous acid gas at a temperature of over 300° C. a blue of moderate depth results. Air-tight crucibles cause

the formation of Ritter's ultramarine white, a pale grey substance which on moderate heating is converted into a fine green. To produce a "pure" blue, a mixture of kaolin, rich in alumina, sodium carbonate and sulphur, in the proportion of equal equivalents of the latter two, is heated with rosin or asphaltum; the lower portion of the contents of the crucible become dull green, the upper being blue, the colour however improving by moderate heating. To obtain a uniformly dark blue mass, silica is mixed with the kaolin, and a larger proportion of sulphur employed than in the last case. This may be burnt either in crucibles or in bulk, the latter method giving a product richer in colour, and one that better withstands the action of alum; but which owing to its containing free sulphur is unavailable for some purposes such as calico printing, the hot rollers employed being liable to injury. This free sulphur can be removed neither by heat nor by boiling with caustic alkalis without injury to the colour; but by boiling the ultramarine in a solution of sodium sulphide by the aid of steam in zinc vessels, the author has succeeded, the colour being often considerably improved by the process.

Chemically pure sodium carbonate and "ammonia soda" make the mass difficult to burn, but on the other hand, a slight addition of caustic alkali or of sodium sulphide is of assistance in the process. The richer the mixture is in silica the more difficult is the burning, but the deeper is the colour of the ultramarine, and the greater its power of resisting the action of alum and weak acids. Oxygen must be carefully excluded during the combustion, as otherwise silica is reformed, which yields with the sodium and aluminium present a hard slag. To avoid this many manufacturers run their furnaces with an insufficient supply of air; this, however, considerably increases the amount of fuel used, beside producing large quantities of smoke. By burning the coal in a separate chamber, and allowing only the flame and hot air to circulate round and through the furnace in which the crucibles or substance in bulk is placed, the author has been able to work with considerably less coal, without producing more than a trace of smoke, and without any deleterious action on the mixture. A further economy is gained by allowing the gases to circulate through another furnace before escaping, which can thereby be raised to a dull red heat. Samples should be taken at intervals during the burning, by means of an iron rod with a spoon-shaped end; these must be kept covered till cold, and when they are found to be dark green the operation is complete.

Ultramarine containing much silica is usually of a reddish-blue colour. To obtain a pure blue, the author heats the mixture in covered crucibles. The green product is powdered and heated in a limited supply of air to a temperature of  $160^{\circ}$ – $180^{\circ}$  and a small quantity of steam; colours varying from greenish-blue to pure blue being obtainable at pleasure. By this method a good blue was formed from a mixture containing 69.32 parts of silica to 50.67 of kaolin, the highest proportion previously available being 66.7 of silica to 33.3 of kaolin.

The crude ultramarine blue contains from 20 to 24 per cent. of free sodium sulphate, which is usually removed after powdering by repeated agitation with hot water. The author recommends that the blue should be mixed with the water to a paste, boiled with steam to dissolve the sulphate, and the mass thrown on to a filter on Bunsen's principle, where the solution is removed under diminished pressure. The filter recommended has a diameter of 1 m. and a depth of 5 m.; 8 cm. from the bottom a perforated tray is fixed, on which a filter cloth is laid, and a manometer to show the pressure. Over the ultramarine a thin sheet of metal provided with small holes is laid, to avoid disturbing the substance during washing. If it be desired to work up the sulphate solution, a small quantity of carbonate should be added to precipitate the dissolved iron.

The final grinding takes place with water under edge-runners, the weight of the runners being supported on a footstep bearing which is adjustable by levers and a counter-balance, so that the pressure on the bed can be altered to suit the fineness of the material. It is then washed and levigated, the finest particles being precipitated by the addition of some salt which has no action on it, e.g., ammonium salts, calcium sulphate, or even hard water.

**Ultramarine violet.**—The first samples of this colour were made under the direction of Leykauf by the ultramarine works at Nuremberg in the year 1859. The process employed was to allow moist calcium chloride to act on ultramarine blue in a warm place. In the year 1872 the author treated ultramarine with chlorine gas at a temperature of  $300^{\circ}$  C.; the mass assumed a reddish-brown colour, which on treatment with water became violet. This colour contained water in combination, and at a high temperature was decomposed into the original blue. A similar brown substance is produced by the action of sulphuric anhydride or sulphur chloride on heated ultramarine. When the chlorine compound is treated with absolute alcohol a reddish-violet substance is obtained containing some organic matter in combination, a smell of ethyl chloride being produced. By leading ammonia gas over the heated chlorine compound, it is absorbed, and a violet colour produced, aniline acting in a similar manner. The violet is also formed by passing a mixture of chlorine and steam over ordinary ultramarine heated to  $160^{\circ}$ – $200^{\circ}$  C.

Mahla heated a mixture of ammonium nitrate and chloride (which decompose in the following manner,  $\text{NH}_4\text{Cl} + 2 \text{NH}_4\text{NO}_3 = 6 \text{H}_2\text{O} + 5 \text{N} + \text{Cl}$ ) and ultramarine to  $200^{\circ}$  C. and directly obtained a fine violet. This compound contains ammonia in combination. In the course of manufacture it has been found that by working in porous crucibles and exposing the mass to a long-continued heat, the addition of nitrate to the mixture is unnecessary. A mixture of hydrochloric acid gas and air has been substituted for the chlorine with success, care being taken to keep the temperature between  $180^{\circ}$  and  $230^{\circ}$ .

The violet produced by the action of moist chlorine differs from the original blue, by having lost one-sixth of its sodium and having gained water and oxygen; the approximate formula for the blue being,  $\text{Na}_6\text{Al}_7\text{Si}_6\text{S}_4\text{O}_{21}$ , and for the violet,  $\text{Na}_5\text{HAl}_7\text{Si}_6\text{S}_4\text{O}_{21} + \text{H}_2\text{O}$ . It also contains much thiosulphate. When treated with iodine solution in excess, decomposed by hydrochloric acid, and the sulphates removed by barium chloride, the tetrathionic acid which is formed by the action of the iodine on the thiosulphate may be oxidised by nitric acid and precipitated as barium sulphate, the yield from violet (calculated as free sulphur) being 2.3 per cent., the blue giving only 0.29 per cent.

For the manufacture of the violet by the action of chlorine and steam, the blue is first spread out in thin layers on earthenware trays, heated in a furnace to  $280^{\circ}$  C., and steam passed over it to remove the sulphur. It is then allowed to cool to  $160^{\circ}$  when a mixture of chlorine and steam is led over it for three hours. Iron, not being attacked by chlorine between  $150^{\circ}$  and  $250^{\circ}$ , may be used for the material of the furnace. Hydrochloric acid may be substituted for the chlorine, the temperature employed being  $220^{\circ}$ – $230^{\circ}$ ; the operation lasts about seven hours, and by allowing the heat gradually to fall to  $160^{\circ}$  the colour of the product becomes very brilliant. For the production of the violet by means of sal-ammoniac with or without the addition of nitrates, the blue is heated with 5 per cent. of ammonium chloride for 14 days in a chamber built over the blue furnaces; when sodium nitrate is added the operation is completed in less time.

Ultramarine violet heated to  $280^{\circ}$  in a stream of hydrogen is converted into a new colouring matter, a light blue. On analysis this substance gives figures closely agreeing with the formula  $\text{Na}_5\text{H}_3\text{Al}_7\text{Si}_6\text{S}_4\text{O}_{25}$ .

Heated to from  $135^{\circ}$ – $145^{\circ}$  in a stream of nitric or hydrochloric acid gas, the violet is converted into ultramarine red, which substance is apparently an acid, whose sodium salt is the violet. Analysis of the red gives  $\text{Na}_3\text{H}_5\text{Al}_7\text{Si}_6\text{S}_4\text{O}_{25}$ .

—F. H. L.

#### ERRATUM.

This Journal, November number, 1890, p. 1046, col. 2, last two paragraphs, for "Oil of Flax," read "Linseed Oil." Also p. 1045, *ibid*, for "Flax" read "Linseed."

## XIV.—TANNING, LEATHER, GLUE, AND SIZE.

### PATENTS.

*Improvements in the Method of and Apparatus for Extracting the Tannin from Bark or other Materials used for Tanning Purposes.* J. Hutchings and W. N. Hutchings, Warrington. Eng. Pat. 20,403, December 18, 1889. *Sd.*

In the centre of an ordinary pit or leach of any convenient size is fixed a square wooden trunk having openings at the bottom. Enclosed by this is a plunger which is a strong wooden box fitting the trunk and about three feet deep. This plunger can be weighted in any convenient way, such as by partially filling with stones, &c., and has a simple pump clack at the bottom. The plunger is connected by a rope with the end of a rocking-beam, by the oscillation of which it is alternately raised and lowered. The mode of working is as follows:—Baskets, half filled with bark, valonia, or other tanning material, are placed in the leach surrounding the trunk till the leach is filled, and water or liquor is then run into the leach. By the movement of the plunger the liquor is kept in constant movement and the soluble constituents of the tanning material are rapidly exhausted. Drawings are given.—B. H.

*Improvements in Machines for Colouring Leather, Skins and like Materials.* C. Knabe, Osterwieck-am-Ilarz, Germany. Eng. Pat. 15,167, September 25, 1890. *6d.*

"The invention consists in the combination of a rotary table on which the material to be coloured is extended, with a colouring drum which is moved to and fro over the table whereby it is at the same time set in rotary motion alternately in the one and in the other direction." Details and drawings of the machine are given in the specification.

—B. H.

## XV.—MANURES, Etc.

*Field Experiments with Swedes.* E. Kinch. Report of the Royal Agricultural College Club, Cirencester, 1889.

In these experiments the same seed, Sutton's "Crimson King Swede," and the same manures were employed during the same season on various soils:—1. Stiff brown clay, on trias, Peplow, Shropshire. 2. Light "hungry" sand on New Red Sandstone, Cheswardine, Staffordshire. 3. Sandy soil, Elstree, Herts. 4. Light soil, St. Alban's, Herts. 5. Rather stoney marl, on Forest Marble, Siddington, Gloucestershire. 6. Red loam on Carboniferous Limestone, Bristol, Somerset. 7. Loam on greensand and gravel, Burecote, Oxon. 8. Calcareous clay, on Great Oolite, Royal Agricultural College, Cirencester. The manures consisted of superphosphate with 26.81 per cent. soluble phosphate, nitrate of soda containing 98.41 per cent. of the pure salt, and Thomas' slag with 17.8 per cent. phosphoric acid, and 85 per cent. passing through a 100-mesh, and over 70 per cent. through a 150-mesh sieve. The following weights of roots in tons and cwt. per acre were obtained under the conditions specified:—

### WITHOUT OTHER MANURE.

8. ....	16 17½	16 17½	19 11	17 15½

From which it will be seen that the superphosphate alone gave an increase in nearly all cases, and generally acted well in conjunction with farmyard manure and in fewer cases with nitrate. Slag alone also gave a good increase in most instances, and in some cases equal to the superphosphate, but it is more uncertain in action than the latter, especially when used with nitrate or farmyard manure. The farmyard manure exhibited a good effect in all cases and the nitrate in most. Soils 2 and 7 were in too good condition to benefit much by the manures.—D. A. L.

*Value of Superphosphate as compared with a Mixture of Ferrons Sulphate and Mineral Phosphate.* P. M. De-lacharlonny. Jour. de l'agricult. 1890, 1, 825—829.

Plots were first dressed with farmyard manure and then with different manurial mixtures:—superphosphate and sodium nitrate with and without potassium sulphate and iron nitrate; superphosphate, potassium sulphate, and iron sulphate; mineral phosphate and iron and potassium sulphates with and without sodium nitrate and potassium nitrate. Vine was cultivated and the wine harvest estimated. The results indicated that not alone could the superphosphate be profitably replaced but even surpassed by the use of the ferrons sulphate and mineral phosphate together.

—D. A. L.

*Behaviour of Sandy Soils towards Superphosphate.* A. Thomson. *Bied. Centr.* **19**, 585—588.

PERCOLATION experiments, made to ascertain the factors influencing the absorption and retention of phosphoric acid by sandy soils, have led to the following conclusions. Phosphoric acid is absorbed and retained most energetically when ferrie and aluminium hydroxides and calcium carbonate are present simultaneously, but separately the hydroxides are more active as absorbents than the calcium carbonate; whilst sand and orthoclase neither absorb nor retain phosphoric acid. Sodium chloride solutions, as compared with distilled water, dissolve less phosphoric acid from superphosphate. They diminish the absorption of phosphoric acid by calcium carbonate (a 1 per cent. solution more than a 2 per cent.), whilst the absorptive power of the hydroxides is augmented by a 1 per cent. common salt solution and is depressed by a 2 per cent. solution. The absorption by the combined absorbents is reduced by both salt solutions to about the same extent. Potassium nitrate behaves in a similar manner to the sodium chloride, but more energetically, and the 2 per cent. solution is in most cases more active than the 1 per cent. solution. Distribution exerts an important influence on the absorption of phosphoric acid, but no simple relationship was noticed between the quantity of phosphoric acid dissolved and the duration of the contact of the solvent with the material. Agriculturally considered superphosphate can only be expected to act as a fertiliser on sandy soil when a large quantity of calcium carbonate or a smaller quantity of both the calcium carbonate and the hydroxides are present, and when there is not too much nitrate either applied to or formed in the soil.—D. A. L.

*Action of Manures containing Thiocyanates (Sulphocyanides).* E. Maek and K. Silen. *Tyroler landw. Blätter*, 1890, **8**, 198—200.

DIMINISHED yields of maize, manured with ammonium sulphate containing ammonium thiocyanate (sulphocyanide), and cut and weighed green, indicate a very great sensitiveness in these plants towards thiocyanates; which became evident even from the generally deteriorated appearance of the plants when the quantity of thiocyanate amounted to 9.0 kilos. per hectare.—D. A. L.

*The Exhaustion of Unmanured Soil.* P. P. Dehérain. *Compt. Rend.* **111**, 253—250.

IN a previous paper (*Compt. Rend.* **109**, 781) an account has been given by the author of experiments made upon land that has not been manured since 1875. He finds that this unmanured soil can yield a good crop of oats and a fair crop of wheat, but that the culture both of beet and of clover is impossible. This ground differs little from well-manured ground in respect to the quantities of nitrogen, of phosphoric acid, and of potash it contains, but it has only half of the amount of carbon derived from organic matter, or 7 grms. per kilo. of soil. There is, further, little difference in the amount of moisture retained by the manured and unmanured soil. To throw further light on the subject the author has examined the drainage water from numerous samples of soils, for it appears from the above that it is organic matter that renders the soil suitable for the growth of beet and clover.

The method of observation adopted was to place the soil in large pots and to collect the drain water by a suitable pot placed below. Manured, unmanured, and meadow soil were examined in this way. There was found to be little variation in the amount of drain water obtained in the three cases, nor do the different quantities of nitric acid found in the drain waters appear sufficient to account for the sterility of the unmanured soil. During the year 1889—90 the soils experimented upon lost 100 grms. of nitric acid, corresponding to 600 grms. of sodium nitrate per hectare, in the drain water. This loss had taken place on soil without any crop on it in the case of the unmanured land, whilst with the manured land the author's experiments go to show that it occurs mainly during the periods between the growth of

crops. To avoid this loss of nitrates it is recommended to sow some rapidly-growing plant, such as rape, immediately after gathering the crop of beet, clover, &c., so that something shall be in the soil which is capable of transforming the nitrates into organic matter. When these plants are ploughed into the soil at the end of autumn or the beginning of spring they restore to the soil the whole of the nitrogen which would otherwise have been lost, and in addition a powerful organic manure which is particularly efficacious for certain kinds of crops.—C. A. K.

*The Treatment of Black-Rot.* A. de l'Écluse. *Compt. Rend.* **111**, 284—285.

IF the leaves of the vine are covered with a composition containing a soluble copper salt or oxide of copper, the black-rot loses the power of germinating and the vine is preserved. This treatment should be constantly applied to all the green parts of the plant at least 12 days before the first attacks of the black-rot are to be expected.

If, however, the leaves are already covered with the pest, the grapes may be still preserved, as long as the peduncle has not been affected, if the composition be applied 15 days before the appearance of any contaminated fruit. In order to ensure complete success by this means the whole of the green surfaces of the vine must be completely covered by the salts of copper during the periods mentioned. It is not sufficient to coat only the upper surfaces of the leaves.—C. A. K.

### XVI.—SUGAR, STARCH, GUM, Etc.

*Studies on Starch.* C. Scheibler and H. Mittelmeier. *Ber.* **23**, 3060—3075.

THIS paper is divided into three parts, in the first and second of which the chemistry of starch is discussed from the historical and theoretical standpoints. For the considerations here involved the original communication must be consulted. In the third portion of their paper the authors describe the results of their investigations on the nature of dextrans. Pure commercial dextrin was used in the experiments. It contained appreciable quantities of glucose indicated by the phenylhydrazine reaction. It was found that the dextrin could be readily purified by repeated precipitation with alcohol, or by osmosis. The sugar-free dextrin thus obtained consisted no doubt of a mixture of several dextrans. The aldehydic character of the dextrin was shown by its behaviour towards various reagents. Its solution was browned by alkalis and distinctly reduced Fehling's solution. The solid dextrin was slowly dissolved in the cold by phenylhydrazine, and this solution yielded on precipitation with alcohol a brilliant white powder, consisting of the *hydrate of dextrin*. This substance is hydrolysed by diastase. It is very soluble in water and

contains 1.02 per cent. of nitrogen. This number gives one a rough idea of the molecular weight of dextrin, as will be seen by comparing it with the percentages of nitrogen contained in different dextrin phenylhydrazones:—

Formula.	Per Cent. N.
$C_{64}H_{112}O_{70}N_2HC_6H_5$ .....	1.18
$C_{96}H_{162}O_{40}N_2HC_6H_5$ .....	1.04
$C_{108}H_{182}O_{90}N_2HC_6H_5$ .....	0.93
$C_{120}H_{202}O_{100}N_2HC_6H_5$ .....	0.84

An osazone was also prepared containing 1.63 per cent. of nitrogen. It forms a yellow powder and is slightly soluble in water.

A cold solution of dextrin treated with sodium amalgam loses its property of reducing Fehling's solution, and is no longer browned by alkalis. The reduction product may be precipitated by means of alcohol, and is obtained as a white powder, which does not dissolve in phenylhydrazine even on warming. The authors propose to name this new body "*dextrite*." Dextrite is saccharified by diastase and by strong acids. By the gradual oxidation of dextrin with bromine, the corresponding carboxylic acid is obtained. It forms a white powder, the solution of which reddens litmus paper and decomposes calcium carbonate on boiling. The solid substance is soluble in phenylhydrazine. The solution of the acid is not precipitated by basic acetate of lead, or by lime water. It does not reduce Fehling's solution, but after boiling with acids, or after treatment with diastase, it acquires a strong reducing action. The comparative ease with which this acid is produced is a further proof of the aldehydic nature of dextrin. Dextrin has been treated with oxidising agents by other observers, but only with the object of destroying sugars, to an admixture with which the reducing power of dextrin was ascribed, the assumption being made that the dextrin itself would not be affected by the reagent employed, such as, for instance, mercuric cyanide. According to the present research it appears that the "non-reducing" dextrin obtained by such a process consists in all probability of the carboxylic acid of dextrin.

The question, whether or not pure dextrin reduces Fehling's solution, is thus answered in the affirmative.

—H. T. P.

*On Sugars richer in Carbon from Rhamnose.* E. Fischer and O. Piloty. Ber. 23, 3102—3110.

RHAMNOSE is a methyl pentose, the formula of the anhydrous sugar being  $CH_3(CH.OH)_4.CO.H$ , and when treated in the way which has been previously described (this Journal, 1890, 638), it yields sugars containing one or several atoms of carbon more. These sugars the authors propose to call rhamno-hexose, rhamno-heptose, rhamno-octose, &c.

*Rhammitol*,  $CH_3(CH.OH)_4.CH_2OH$ , is the pentahydric alcohol obtained by the reduction of rhamnose by sodium amalgam. In order to obtain a crystallisable product, a 10 per cent. solution of rhamnose is shaken with  $2\frac{1}{2}$  per cent. sodium amalgam, and kept cool. During the first half of the reaction the solution is kept just acid with sulphuric acid, and during the latter half just alkaline.

The reduced alkaline solution is filtered, neutralised with sulphuric acid, evaporated on the water-bath, and the syrup taken up with hot absolute alcohol. On evaporation, the alcoholic solution yields a syrup, which crystallises on cooling. The yield is about 60 per cent. on the sugar taken. The recrystallised rhammitol tastes sweet, melting point  $121^\circ C.$ , and distils partly undecomposed. It is easily soluble in water and alcohol, with difficulty in chloroform and acetone, and is almost insoluble in ether. A concentrated solution in acetone deposits fine globules, which crystallise, and grow to fairly large triclinic prisms. A solution of rhammitol is optically active  $[\alpha]_D = +10.7^\circ$ ; it does not reduce Fehling's solution.

*Rhamno-hexonic Acid*,  $CH_3(CH.OH)_5.CO.OH$ .—This has previously been described as iso-dulcitol-carboxylic acid (this Journal, 1888, 636). An aqueous solution is dextro-rotatory,  $[\alpha]_D = +83.8$ .

*Rhamno-hexose*,  $CH_3(CH.OH)_5.CO.H$ , is obtained by reducing a solution of the lactone of rhamno-hexonic acid by  $2\frac{1}{2}$  per cent. sodium amalgam. The solution must be kept cool and acid by the addition of dilute sulphuric acid as the reaction proceeds. The reduced solution is filtered, and sufficient soda added to give an alkaline reaction after standing a quarter of an hour. The solution is then just neutralised with sulphuric acid, evaporated to a syrup, and the chief portion of sodium sulphate removed by crystallisation, and the mother-liquor taken up by boiling absolute alcohol. The sodium salt is precipitated, and the sugar remains in solution, which crystallises from the syrup obtained by evaporating the alcoholic solution. The yield is 60—65 per cent. of the lactose taken. It crystallises in well-formed short columns on thick tables, melting point  $180^\circ$ — $181^\circ$ , without decomposition. It differs from rhamnose in crystallising in the anhydrous state. It is difficultly soluble in absolute alcohol, but more easily in hot methyl alcohol. Its aqueous solution tastes sweet, and gives all the ordinary sugar reactions, and does not ferment with beer yeast. It is levo-rotatory, having  $[\alpha]_D = -61.1$ .

*Rhamno-hexosazone*,  $C_7H_{13}O_7(N_2H.C_6H_5)_2$ , is obtained in the usual way, in fine yellow needles, melting point  $200^\circ$  with decomposition. It resembles rhamnosazone in being easily soluble in hot alcohol, but almost insoluble in water.

*Rhamno-hexitol*,  $CH_3(CH.OH)_5.CH_2OH$ , is prepared from rhamno-hexose, just as rhammitol is from rhamnose. It crystallises from hot alcohol in small colourless prisms, melting point  $173^\circ$ ; it does not reduce Fehling's solution, and is dextro-rotatory,  $[\alpha]_D = +11.6$ .

*Rhamno-heptonic Acid*,  $CH_3(CH.OH)_6.CO.OH$ . By acting on rhamno-hexose with hydrocyanic acid in aqueous solution, the amide of rhamno-heptonic acid separates in two days. The mixture is then heated on the water-bath until all the hydrocyanic acid is expelled, and then a solution of baryta added and evaporated on the water-bath until all smell of ammonia disappears. All baryta is then removed by sulphuric acid, and the solution evaporated to a syrup, from which the lactone crystallises, and which is purified by recrystallisation from alcohol. The yield is 65 per cent. on the sugar taken. The lactone melts  $160^\circ$ ; it is very easily soluble in water, fairly soluble in ethyl and methyl alcohol, and insoluble in ether. Its aqueous solutions are dextro-rotatory,  $[\alpha]_D = +55.6$ .

*Rhamno-heptonic Acid hydrazide*,  $C_8H_{15}O_7.N_2H_2.C_6H_5$ , forms fine white needles; it becomes coloured when quickly heated to  $215^\circ$ , and melts a few degrees higher. It is fairly easily soluble in hot water, and almost insoluble in cold water and alcohol.

*Rhamno-heptose*,  $CH_3(CH.OH)_6.CO.H$ , is obtained by reducing the lactone of rhamno-heptonic acid. It forms a colourless syrup, easily soluble in alcohol and water, but not in ether. It has not been crystallised. To obtain it free from ash, it is converted into the hydrazone, which is with difficulty soluble in water, and may be easily purified and the sugar re-obtained from it. Aqueous solutions of the sugar are dextro-rotatory,  $[\alpha]_D = +8.4$ . The hydrazone has a composition corresponding to the formula  $C_8H_{16}O_6.N_2H.C_6H_5$ , melting point  $200^\circ$ , with decomposition. The sugar also yields an osazone,  $C_8H_{14}O_5.(N_2H.C_6H_5)_2$ , which crystallises in fine yellow needles, melting point  $200^\circ$  with decomposition. It is only slightly soluble in hot alcohol.

*Rhamnose-octonic Acid*,  $CH_3(CH.OH)_7.CO.OH$ , is produced by the action of hydrocyanic acid on rhamno-heptose in a similar manner to the production of rhamno-heptonic acid from rhamno-hexose. The lactone is purified by recrystallisation from acetone. It melts at  $171^\circ$ — $172^\circ$ , and is easily soluble in water and alcohol. Its aqueous solutions are levo-rotatory  $[\alpha]_D = -51.2$ . It yields a phenylhydrazide  $CH_3(CH.OH)_7.CO.N_2H_2.C_6H_5$ , with difficulty soluble in hot water, melting point  $220^\circ$  with decomposition. It crystallises in fine white needles.

A sugar is obtained by the reduction of rhamnose-oetonic acid which is doubtless rhamno-oetose. The authors had not sufficient material to properly determine its characteristics, but they prepared its osazone, melting point  $216^{\circ}$ , and found that the sugar reduced Fehling's solution.

—A. L. S.

*Improvements in Sugar Refining.* E. O. Lippmann. Chem. Zeit. 14, 1405—1406 and 1425—1426.

LAST year the author reported on Steffen's and Seyferth's sugar-refining processes (see this Journal, 1889, 993), and at the time expressed his opinion that their practical merits would most likely be decided during the following season. As regards Steffen's method it has shown itself to be of great value, and the adoption of a considerable number of deep troughs, permitting the washing of thicker layers of sugar, has been found practicable. In the case of raw sugars it is of importance to choose uniform, well-grained, and not too moist samples, since such specimens are most readily washed. A period of 8—10 hours was at first supposed to be sufficient for washing; but later experience shows that 12—15 or even 16 hours are necessary. All kinds of irregularly-grained, moist, and pasty samples containing invert-sugar are unsuitable for purification by this process. The washing of charges ("Füllmassen") presents no difficulties, provided they are properly boiled and sufficient time be given. Steffen's process is particularly adapted to the direct production of white sugar; the raw sugar treated must, however, be of fairly good quality. As regards the yield of sugar obtainable by Steffen's process, it is stated that a raw sugar containing 88—92 per cent. of cane sugar gives about the same absolute quantity of crystal sugar polarising  $99.5-99.9$ . As regards the quantity of pure syrup required to wash a raw sugar, it depends on the amount of molasses adhering to the latter. The pure syrup finally left in contact with the washed mass may be removed by centrifuging, and used over again. This fact has led some observers to state that there is no consumption of pure syrup at all; in other words, that an unlimited amount of raw sugar may be washed with a given quantity of syrup. In practice, however, it is impossible to prevent the pure syrup from mixing to some extent with the molasses it is intended to displace. The consumption of pure syrup is variously estimated at from 2 to 5 per cent. The cost of working Steffen's process is slight. The washing of 2—3,000 centners of sugar daily requires an engine of 55—60 H.P.; whilst the wages to be paid amount to about 10 pf. per centner. On the other hand the cost of plant, and the royalty to be paid to the inventor, are extraordinarily high.

Seyferth's paraffin method is in every respect a complete failure. It has, however, given rise to the Waghäuser refining process, which appears to be a combined centrifuging and washing method. Ten centrifugal machines, taking a charge of 150 kilos. each, are said to refine 40,000 kilos. of raw sugar in 20 hours, six workmen being required.

Foelsche employs a battery of centrifugal machines, fitted with non-perforated drums, the syrup being skimmed off as in milk centrifugals. The raw sugar is treated in the centrifugals with syrup or steam or both. The results obtained by this process are said to be excellent. Drost and Schulz's method aims at the direct production of crystallised cane from beet-sugar mass. The beet-sugar mass freed from green syrup by centrifuging is washed with 8—10 per cent. of filtered thick beet-juice at  $66^{\circ}-67^{\circ}$  B. Finally, steam is allowed to act on the crystals for several minutes. 2—3 per cent. of the solid sugar are dissolved by this means, and the syrup produced, as well as the thick juice used for washing, are boiled down for sugar. The operation requires 30 minutes for its completion. A raw sugar containing 86.1 per cent. of cane (by polarisation) and 7 per cent. of water was treated with thick juice having a purity coefficient of 91.5; 63—64 per cent. of crystallised sugar, polarising  $99.7$ , and green syrup of 71 purity coefficient were obtained finally.

—H. T. P.

*Gum from Beetroot.* Deutsche Zuckerind. 15, 1128.

EICHELMANN has succeeded by heating together at a temperature of  $120^{\circ}-200^{\circ}$  dried shreds of beet with 20 per cent. of caustic lime, and removing the excess of lime from the aqueous solution by carbonic acid, and the products of the decomposition of the albuminoids by alcohol, in producing a gum, which, in its adhesive properties, is hardly inferior to gum arabic.—F. H. L.

## XVII.—BREWING, WINES, SPIRITS, Etc.

*Recent Progress in Brewing.* Dingl. Polyt. J. 277, 133—135.

CRISMER (Weinlaube, 1889, 210) recommends saffranine as a reagent for dextrose, used as follows:—2 to 3 cc. of saffranine solution of 1 per cent. strength are heated with 2 to 3 cc. of caustic soda solution of 10 per cent. The colouration disappears at  $60^{\circ}$  or  $65^{\circ}$  C., if some drops of dextrose solution be added. After some time, red lines appear on the surface of the liquid, where the saffranine reappears by oxidation.

J. Geyer confirms (Pharm. Zeit. 1889, 683) the experiment made by Thierfelder, viz., that potassium glucuronate ( $C_6H_7KO_9$ ) forms a compound with phenylhydrazine very similar to the one sugar producees. Therefore this reaction is not always reliable.

E. Preuss (Zeits. f. Rübenzuckerind. 1890, 18) recommends the following preparation of Soldani's reagent for the determination of invert sugar:—15.9 grms. of copper sulphate are added to a hot solution of 594 grms. of potassium bicarbonate, and, when cold, diluted to 2,000 cc. This solution, which does not easily decompose, has a specific gravity of 1.1789. The test is made as follows:—150 cc. of this reagent are heated to boiling, and after the invert sugar solution is added, the boiling is continued for 10 minutes. The following quantities of copper and invert sugar are equivalent:—

Copper.	Invert Sugar.	Copper.	Invert Sugar.
Mgrms.	Mgrms.	Mgrms.	Mgrms.
18.8	5	142.4	45
34.9	10	157.0	50
50.9	15	171.3	55
66.6	20	185.5	60
82.2	25	200.4	65
97.6	30	213.1	70
112.7	35	226.6	75
127.8	40	240.6	80

(Compare this Journal, 1890, 825.)

HERZFELD (Zeits. f. Zuckerind. 1890, 52), in criticising the general application of Soldani's reagent, points out that, compared with Fehling's reagent, it contains only the fifth part of copper, and may therefore be less sensitive; also that its power of dissolving lime is less; that it precipitates cupric oxide when highly diluted, and more cuprous oxide when strongly boiled.

*Application of Electrolysis in Sugar Determination.*—As caustic potash has sometimes an injurious effect upon asbestos, Formanek (Böhm Zeits. f. Zuckerind. 1890, 178) recal dextrins. The aldehyde & the cuprous oxide on pal shown by its behaviour toward tartaric acid, &c. This has been done long ago by Märcker, but has been left as inaccurate. Asbestos, which shows the above-named deficiency, should first be boiled with caustic potash and nitric acid.—H. S.

*On the Furfural-yielding Bodies from Wheat and Rye Chaff.* E. Steiger and E. Schulze. Ber. **23**, 3110—3113.

It has been known for some time that furfural is produced by distilling wheat and rye chaff with sulphuric acid. It is also known that when arabinose or xylose, or those bodies which yield one of these sugars on hydrolysis, are distilled with sulphuric acid in the same way, they also yield furfural. Although Stone and Tollens (Ann. **249**, 239) obtained an osazone from the products obtained by digesting wheat or rye chaff with sulphuric acid, which osazone possessed all the properties of arabinosazone, yet they were unable to isolate arabinose from these solutions.

The authors have re-investigated these products, and have succeeded in crystallising arabinose from them, which they have identified by its crystalline form, optical activity, &c. They consider that the body which yields arabinose on hydrolysis is a constituent of the cell membrane. Owing to the difficulty of separating it from the cellulose, it is impossible to determine its properties with any degree of completeness. It is insoluble in water, in very dilute alkali, in very dilute mineral acids, in solutions of diastase and digestive ferments.

The mother-liquors left after the crystallisation of arabinose have a considerably lower optical activity than arabinose; on account of this the authors suspect the presence of xylose.—A. L. S.

#### *The Analysis of Malt.* Chem. Zeit. **14**, 1368.

THE agricultural section of the International Agriculture and Forestry Congress at Vienna discussed a uniform system for the analysis of malt. The following points were agreed upon:—

1. *Sampling.*—The sample must represent a true average sample. This is best done by well mixing the malt-heap by a shovel, taking samples from different parts of the heap, well mixing these, and from this taking the sample for analysis. If this cannot be done, a sampling stick may be used. Under no circumstances should the sample be taken from the upper part of the malt-heap. The samples must be stored in tightly closed bottles or tin canisters. When sending it for analysis, the reason for doing so should be stated, the temperature at which it was dried, and the origin of the barley.

2. *Determination of the Moisture.*—About 5 grms. of malt are weighed between two watch glasses, ground in a mill, and the ground malt dried either in an air-bath or, preferably, in a water-oven. If the air-bath be used, the drying should not exceed four hours, if the water-bath, the heating should be continued until the malt ceases to lose weight. The difference between two experiments should not exceed 0.25 per cent. The temperature should be 97°–105° C. If the malt is very damp, the drying must commence at a lower temperature.

3. *Determination of the Extract.*—50 grms. of malt are ground and digested with 200 cc. of water at 45° C. for half an hour, the temperature is then allowed to rise to 70° C. at the rate of 1° C. rise per minute; this temperature will then be reached in 25 minutes, the mash is kept at 70° C. for one hour, it is then quickly cooled to 20° C., and the weight of the mash made up to 450 grms. by the addition of distilled water. The iodine colouration is to be taken 10 minutes after reaching 70° and every five minutes after. The mash is filtered through a large folded filter, the first 100 cc. being returned to the filter. The funnel is kept covered, and the filtrate received in a dry stoppered bottle. It is unnecessary to wait until the whole of the wort has been filtered. The odour and the clearness of the wort are to be noted. The colour is determined by comparison with solutions of iodine. The specific gravity by the pycnometer at 15° or 17.5° C., and the determinations converted into the amount of solid matter by Balling's tables.

The analysis of roasted malt is to be made with 25 grms., to which are added 25 grms. of malt of which the extract yield is known.

4. *The Determination of Maltose.*—25 cc. of wort are diluted to 200 cc., and 25 cc. of the dilute solution taken and boiled with 50 cc. of Fehling's solution for four minutes, the determination being made according to Soxhlet's directions.—A. L. S.

#### *Quinine Wine.* Pharm. Zeit. 1890, **35**, 371.

FIFTY grms. of powdered Peruvian bark are macerated with 50 grms. alcohol and 450 grms. of water for two days. After pressing, the bark is again treated in the same way. The mixed extract is evaporated to 100 grms., allowed to stand two days, filtered and evaporated to a thin syrup. This is dissolved in 50 grms. glycerol and 150 grms. of sugar syrup; 1 gm. of citric acid, 40 grms. of cognac and 760 grms. of sherry added, allowed to stand 14 days in a cool place and filtered. This wine is efficient, stable, and remains clear at ordinary temperatures.—A. L. S.

## XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

### (A.)—CHEMISTRY OF FOOD.

*Freezing Meat by means of Cold Liquids.* T. Schloesing. Compt. Rend. **111**, 85–89.

A COMMISSION instituted by the French Minister of War, under the presidency of Berthelot, to inquire into the best method of freezing meat rapidly and of preserving it at a low temperature, has adopted the following arrangement as the most suitable. The cooling is effected by means of air, which latter is itself cooled by passing down a coke tower, up which a current of cold liquid is forced. This

tower is fixed in the centre of the cylindrical space in which the meat is placed and has a ventilator on the top which serves to draw in the air to be cooled, which then passes over the coke and down into the chamber containing the meat; as this air becomes heated, it rises and is then again drawn through the coke tower and this process repeated. The tower is made of wood and rests on wooden blocks. The freezing liquid is conveyed from the freezing machine by an iron tube to the axis of the tower, and from this tube a number of lead tubes furnished with numerous orifices branch off horizontally. The liquid as it runs down is collected in a leaden vessel and taken back to the freezing machine. To prevent the calcium chloride added to the freezing liquid in order to keep it liquid, coming in contact with the meat, the tower is surrounded by a jacket made of planks of wood. Details of the arrangements for hanging up the meat to be frozen and of the precautions taken to prevent the access of heat from the outside are given. The diameter of the tower employed was 2 metres, but its size must be regulated by that of the room in which the meat is frozen.—C. A. K.

#### PATENT.

*New or Improved Means and Apparatus for Indicating the Fermenting State or Condition of "Sponge" or Dough preparatory to Baking or Cooking the same; applicable also to Indicating the Fermentation of other Substances and Fluids.* A. F. Garrood, Leytonstone. Eng. Pat. 6341, April 25, 1890. 8d.

THE invention has for its object the indication of the condition of "sponge" or dough during the process of fermentation by giving an alarm signal by means of an electric bell or otherwise, actuated by the movement of the dough, &c. The invention may be adapted for brewing and other analogous processes of fermentation.—V. H. V.

#### (B.)—SANITARY CHEMISTRY.

##### PATENTS.

*Improvements in the Treatment of Sewage and Sewage Matters and in the Production of Fertilising Products therefrom.* U. B. Kemshead, Mitcham. Eng. Pat. 18,677, November 21, 1889. 4d.

THE sewage is received in a circular tank and there is disinfected together with the admixed water, by the addition of a disinfecting powder known commercially under the name of "Smith's Disinfecting Cleaning Powder." Other powders may be used provided they contain neither lime, chlorine, nor carbolic acid. The powder, in the proportion of about 1 lb. to about 3 to 4 gallons of sewage, is well mixed by means of an agitator and the whole allowed to stand for two or three hours. The surplus water is separated by filtration and might at once be run into a stream, but as it contains a certain quantity of ammoniacal salts in solution it is preferably used for irrigating a sewage farm. The sludge when mixed with potassium and ammonium sulphate (the refuse from gasworks) may be used as a fertiliser for root-crops and ordinary purposes; the proportion adopted is 1 lb. of each of the salts to about 4 gallons of sludge. If used for cereal crops, 1 lb. of soluble potassium silicate is added. These admixtures are then mixed with loam or peat earth or road sweepings and the whole dried like bricks. The cakes of material can be reduced to powder and are then ready for packing in tins.—V. H. V.

*Improvements in the Treatment of Organic Matters for the Production of Manures, and in Apparatus therefor.* J. Guillaumie, Paris, France. Eng. Pat. 5419, April 9, 1890. 11d.

THE refuse matter, raw or solid, containing about 87 per cent. of water, is diverted into a receiving basin, in which air is forced under a pressure of 25 cms. of water. The raw material is herein acidified with sulphuric acid, an

operation which has the double advantage of partially disinfecting it and of fixing the ammoniacal products. The material is then carried automatically by an elevator into a reservoir, whence it is distributed into a desiccator; in this the materials come in contact with air supplied from a furnace by a ventilator at the rate of 24,000 cubic metres per hour at a temperature of 350°–400°. Bucket wheels on a horizontal shaft are situated in the centre of the desiccator by means of which the matter is lifted up and allowed to fall again in a shower on the hot current of air. By this means the mass loses the greater part of the water, and the air proceeding from the apparatus, and therefore saturated with aqueous vapour and mixed with the noxious gas, is conducted by a tunnel into the drying room. This consists of a large chamber, the raised floor of which is constructed of cast-iron plates, on which the substances containing about 40 per cent. of moisture are placed. The hot air circulating under the plates completes the desiccation and the matter is then ready for agricultural purposes. The air leaving the drying room is conveyed into a refrigerator in which it comes in contact with a fine spray of water, whereby the vapour is condensed; it then passes into the drying room formed of several circulating chambers filled with fagots to retain the moisture. The comparatively dry air is then passed through a tunnel and carried into the furnace where it is burnt, thereby saving fuel. The whole of the work is effected in closed vessels and without contact with the outside air except that drawn in by the ventilator to compensate for the loss of oxygen resulting from the combustion. The specification is accompanied by illustrative plans.—V. H. V.

#### (C.)—DISINFECTANTS.

*Tar Soaps and "Lysol," a New Disinfectant.* C. Engler. Dingl. Polyt. J. 278, 26–34 and 78–83; Pharm. Centrallhalle, 1890, 449.

See under XII., page 1136.

##### PATENTS.

*Improvements in Disinfectants and Deodorisers.* J. Price, London. Eng. Pat. 18,512, November 19, 1889. 6d.

THE material consists of one part of sodium manganate,  $1\frac{1}{2}$  parts of chloride of lime, and  $17\frac{1}{2}$  parts of salt cake. This mixture is prepared in a dry state, and when exposed gives off chlorine for a week or more without appreciable deliquescence; after exposure it is almost as efficacious for treating foul water or putting down drains. On account of its solubility it presents advantages over similar mixtures made up with lime, chalk, or sawdust, which choke up the drains and sewers. It is proposed to call the above mixture "sal-ozone."—V. H. V.

*Improvements in the Process of Producing Disinfectants.* A. Artmann, Braunschweig, and H. W. Kufcke, Hamburg, Germany. Eng. Pat. 20,231, December 16, 1889. 4d.

JEYES' disinfectant, or "creolin," consists of a mixture of tar oils containing carbolic acid of high boiling point, with small quantities of a pyridine base and caustic soda, resin, soap, and water. This disinfectant is easily soluble in water, but loses its emulsive power when hydrochloric acid, or sulphuric acid, or soda lye, &c. is added to it. As its disinfecting quality depends upon the presence of carbolic acid, its employment for many purposes is dangerous.

According to this invention, coal-tar oil, freed from carbolic acid, and of boiling point 180°–220° C., is shaken up with concentrated sulphuric acid in small quantities at a time (about 4 per cent. of the tar) at ordinary temperature. This process is continued until a sample, when shaken up with water, has a milky appearance. The tar oil thus heated with sulphuric acid, and partly converted into sulphonic acids and sulphones, is shaken up with water, and the milky liquid which contains the sulphonated hydrocarbon is separated from the undissolved tar oils,

which rise to the surface. The milky liquid is then heated with hydrochloric acid or common salt, when it separates in two layers, the upper one of which contains the sulpho-nated compound. This is separated off, neutralised with soda, then heated with spirit or other suitable solvent, and then submitted to distillation to remove the solvent; the remaining portion is mixed with a neutral coal-tar hydrocarbon. It is proposed to call the product formed "Artmann's creolin;" it possesses disinfecting qualities, and gives a durable emulsion with water, but it is not poisonous. A certain proportion of carbolic acid may be added; the mixture is then called "Artmann's basic creolin."

—V. H. V.

## XIX.—PAPER, PASTEBOARD, Etc.

*Distinction between Genuine and Imitation Parchment Paper.* E. Muth. Dingl. Polyt. J. **277**, 360—361.

See under XXIII., page 1156.

*Some New Processes in Paper Manufacture.* A. Haussner. Dingl. Polyt. J. **277**, 118—121.

INSTEAD of boiling rags in paper manufacture with lime, it has been recommended that a substance called "ammonine" should be used, a grey powder consisting, according to Dennewitz, of carbonate and silicate of soda, to which a considerable quantity of carbon bisulphide has been added. Its chief value is that it cleanses animal as well as vegetable fibres thoroughly without injuring them. Instead of subjecting the rags to boiling heat, a temperature of only 60° C. is applied, 5 kilos. of "ammonine" and 300 litres of water being necessary for every 100 kilos. of rags. The time of treatment is from half an hour to one hour. Coloured rags have to be treated with soda as well.

It has further been recommended of late to wash the rags in specially constructed washing machines, and not in the beaters, as is often done. But it seems to be difficult to construct a washing machine which is not injurious to the fibres, and it seems best to use modifications of the beaters, fitted with rolls without knives.

For the bleaching of rags, the so-called "oil-bleaching process" has been recommended lately. It was accidentally discovered that certain oils obtained from bituminous slate have a purifying influence upon rags, if added to them during the boiling process, a great saving of other bleaching materials being hereby effected. The quantity of oil to be used varies according to the nature of the rags, as follows:—

	Cc. of Oil.	
1. For linen rags (coarse sacking).....	700—900	For every 100 kilos.
2. For dyed cotton rags.....	700	
3. For bleached rags.....	500	
4. For esparto.....	1,400—1,800	

This process has also been used, with good results, for lignified substances and for straw. Easily inflammable oils have to be avoided as dangerous. A satisfactory explanation of this method has hitherto not been given, but its influence seems to be more mechanical than chemical. It is of special advantage if applied in connexion with the lime treatment of rags. Frank is of opinion that these oils may be used with advantage also in the treatment of sulphite cellulose, in order to obviate the difficulties which are sometimes caused by resinous secretions in the raw materials.—H. S.

*Percentage of Cellulose in Wood.* Papier Zeit.; and Chem. Trade J. 1890, **7**, 335.

See under XXIII., page 1156.

*A Quantitative Reaction for Lignin.* R. Benedikt and M. Bamberger. Monatsh. **11**, 260—267.

See under XXIII., page 1156.

## PATENTS.

*Improvements in Apparatus for Boiling Esparto Grass and other Materials.* G. W. Hawksley, Sheffield. Eng. Pat. 4976, March 31, 1890. 6d.

IN a cylindrical or other shaped vessel an upright cylinder is fixed, containing a series of vertical tubes. Steam admitted to the cylinder heats the liquor contained in the vertical tubes, causing it to rise and overflow, thus producing a rapid circulation.—E. J. B.

*Improvements in the Manufacture of Absorbent Sheets, Rolls, or Pads of Paper for Blotting, Filtering, and other Similar Purposes.* E. G. Wrigley, Preston. Eng. Pat. 5500, April 11, 1890. 4d.

THE inventor claims the combination of wood cellulose with cotton rags and vegetable fibres of a grassy nature, paper so made being more absorbent than one made entirely of cotton rags or wood pulp. Instead of passing the web of paper through press rolls it is pressed between two felts, the fibres thereby being kept more open.—E. J. B.

## XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

*Indian Geranium Oil.* F. W. Semmler. Ber. **23**, 2965—2968.

IN a previous paper (this Journal, 1890, 889) the author has shown that the substance geraniol,  $C_{10}H_{18}O$ , obtained from geranium oil, is probably an open chain compound. An examination of bodies of the same formula, obtained from coriander oil, bergamot oil, and other ethereal oils, seems to show that these latter are also similarly constituted. A difficulty in the previous attempts made to prove the presence of the alcohol group in geraniol was introduced by all the derivatives prepared being non-crystalline. With the hope of obtaining a crystalline product geraniol was oxidised, when a body,  $C_{10}H_{16}O$ , resulted, which formed a crystalline acid sulphite. The oxidation was effected by means of chromic acid mixture, the product of the reaction being made slightly alkaline, and then distilled with steam, when the oxidation product passed over as an oil possessing a lemon-like smell. Several substances appeared to be formed in the oxidation—including terpenes—but the chief product was the body  $C_{10}H_{16}O$ , which was separated by shaking with acid sodium sulphite and decomposing the resulting crystalline compound, after washing with ether to remove adhering oily substances, with sodium carbonate. A colourless oil was obtained, whose analysis and a vapour density determination corresponded to the above formula. This substance, which contains two atoms of hydrogen less than geraniol, must either be a ketone or an aldehyde; from some of its properties the latter appears more probable. Details are reserved for a future paper.—C. A. K.

*The Alkaloids of the Areca Nut.* E. Jahns. Ber. **23**, 2972—2978.

THE areca nut (from *Areca catechu*) contains several alkaloids, including arecoline,  $C_8H_{13}NO_2$ , arecaine—

and a third basic substance which only occurs in small quantities (this Journal, 1889, 210). This last has proved to be nothing more nor less than choline, which was identified by means of its platinum double chloride. This salt separates in monoclinic crystals from aqueous solution; from alcoholic solution yellow octahedra, containing 1 mol. of water of crystallisation, are formed. It melts at 225°; the gold double chloride of choline at 244°—245°.

*Arecoline.*—When heated with hydrochloric acid in a closed tube to 150°—160° arecoline is decomposed with liberation of methyl chloride and formation of a body, arecaine,  $C_7H_{11}NO_2$ , isomeric with arecaine. This decomposition is effected with hydriodic acid by simple boiling, whilst caustic potash and baryta water decompose the arecoline still more readily—partial decomposition taking place in the cold on prolonged standing. Owing to this action of alkalis on arecoline the former should not be employed in extracting the latter from areca nuts, but the method described by the author (v. ante) in which dilute sulphuric acid is used should be substituted.

*Arecaine*,  $C_7H_{11}NO_2 + H_2O$ .—The product of the above reaction when crystallised from 60—70 per cent. alcohol forms colourless tabular crystals, containing 1 mol. of water of crystallisation, which they lose at 100°. It is soluble in water and in dilute alcohol; almost insoluble in absolute alcohol and insoluble in ether, chloroform and benzene. The dehydrated substance melts at 222°—223°, and carbonises on further heating. Like arecaine, arecaine has no poisonous action. It forms salts with acids which dissolve readily in water, with difficulty in alcohol, and which have an acid reaction. The platinum double chloride forms yellow octahedra which melt at 208°—209°; the gold double chloride crystallises in prisms, melting at 197°—198°. By passing hydrochloric acid gas into arecaine suspended in methyl alcohol, arecoline is formed, so that the latter appears as the methyl derivative of the former, a fact which is evident from the method of preparation of arecaine.

*Homarecoline*,  $C_9H_{15}NO_2$ .—This is the name given to the ethyl compound derived from arecaine by treatment with gaseous hydrochloric acid in presence of ethyl alcohol. It closely resembles arecoline, forming a strongly alkaline liquid, miscible with water, alcohol and ether in all proportions, distilling without decomposition and readily volatile with steam. It is poisonous, like its lower homologue arecoline. Of its salts the hydrochloride and gold and platinum double chlorides are described. The author regards arecaine as a weak monobasic acid, a fact borne out by its forming compounds with basic oxides and by its decomposing carbonates. It does not form an acetyl compound, and therefore it is not likely that the hydroxyl group is present, so that arecoline may be looked upon as the methyl ester of an acid,  $C_6H_{10}N.CO.OH$ . The nature of the nitrogenous nucleus  $C_6H_{10}N$  is under investigation.

—C. A. K.

*Poisonous Character of Diamide.* O. Loew. Ber. **23**, 3203—3206.

DIAMIDE, like hydroxylamine, is a strong poison in the case of the most different organisms; it is a poison of universal character. Both bodies distinguish themselves in their chemical relations by their energetic action on aldehydes and ketones. The author has already shown (Ber. Ges. Morph. und Physiolog. in München, 1888, 126) that the poisonous nature of hydroxylamine cannot depend on any conversion it may undergo into nitrous acid.

*Strychnine.* C. Stöckh. J. prakt. Chem. **42**, 399—415.

STRYCHNINE hydrochloride crystallises with  $1\frac{1}{2}$  molecules of water which are driven off at 150° or on prolonged standing over sulphuric acid; the hydrobromide contains 1 molecule of water of crystallisation, and both salts are very hygroscopic in the dehydrated state. The hydriodide is readily precipitated on the addition of potassium iodide to either of the foregoing, being almost insoluble in cold water; it also crystallises with 1 molecule of water. Analyses of these salts, as well as of the platinum double chloride, point to the generally accepted formula,  $C_{21}H_{22}N_2O_5$ , for strychnine. The melting point of the free base was found to be 269° C. The products of distillation of strychnine and lime have been previously examined by the author. The gaseous products were found to be hydrogen, ethylene and ammonia, whilst the liquid distillate consisted of an aqueous and an oily layer, in which ammonia and  $\beta$ -picoline were found. Ethylamine was also found in the aqueous portion of the distillate, whilst the oily portion contains skatole,  $\beta$ -picoline and perhaps  $\beta$ -ethylpyridine. The  $\beta$ -picoline boiled at 142°—143°, and the author does not consider that the differences in the boiling points of the  $\beta$ -picoline thus obtained, and that prepared by other processes (coal-tar  $\beta$ -picoline boils at 144°—148°, and that prepared by various synthetical methods between the extreme limits of 140°—146°) justify one in the assumption that there are two  $\beta$ -picolines (vide Ladenburg, Ber. **23**, 2688), but is of opinion that all the  $\beta$ -picolines hitherto prepared are identical. The author has shown in a previous paper that the study of the action of hydrochloric acid on strychnine led to no positive conclusions as to the manner in which the oxygen atoms are combined in the strychnine molecule, and he has therefore investigated the action of phosphorus pentachloride on the alkaloid with the same point in view. The two substances were heated together in chloroform solution on the water-bath until hydrochloric acid was no longer evolved, the product of the reaction poured into water, made alkaline with ammonia, and extracted with ether. The chief product of the reaction is a trichloro-strychnine,  $C_{21}H_{19}Cl_3N_2O_5$ , which somewhat resembles the substance described by Richet and Bouchardat's (Compt. Rend. **91**, 990) as monochlorostrychnine. It is insoluble in water, soluble in alcohol with a red colour, and separates from this solution in microscopic crystals. It possesses the bitter taste of strychnine, though this property is not quite so marked, and gives similar colour reactions. On heating it decomposes without melting. It is basic and forms a characteristic hydrochloride, platinum double chloride and sulphate; an analysis of the first of these is given. A secondary product of the action of phosphorus pentachloride is a chlorinated body, possessing no basic properties, and probably a mixture of tetra- and pentachlorostrychnine. It melts at 224°, darkening somewhat. The yield of this substance is very meagre.

This result leaves no doubt as to the absence of a hydroxyl group in strychnine, but the author hopes to be able to gain more insight into the constitution of the alkaloid by a study of the oxidation products with potassium permanganate, on which he is now engaged.—C. A. K.

*Brucine.* L. Berend and C. Stöckh. J. prakt. Chem. **42**, 415—420.

BRUCINE, when distilled with lime, evolves hydrogen, ethylene and ammonia as gaseous products, whilst the liquid distillate contains a little skatole, methylamine, and a methyl pyridine identical in its properties and boiling point (142°—143°) with the  $\beta$ -picoline obtained by the treatment of strychnine under similar conditions. (See previous abstract.)

The analysis of the free base and of its platinum chloride establish the formula  $C_{21}H_{22}N_2$ , and there is no doubt of the complete identity of the two picolines obtained from strychnine and brucine respectively. The  $\beta$ -picoline has a sp. gr. of 0.9756 at 0°; Zanoni found this value 0.9771. A lutidine, perhaps  $\beta$ -ethyl pyridine, is also found in the distillate, which is, however, free from quinoline bases.

—C. A. K.

*The Alkaloids of Atropa Belladonna.* E. Schmidt.

Apoth. Zeit. 5, 511.

THE author has examined the roots of *Atropa belladonna* in order to test the correctness of the assertion made by the authorities of Schering's Factory, that good belladonna roots contain only hyoscyamine and no atropine at all. The roots examined were of one, two, eight, and more years' growth. They were collected in spring; in summer, when the plants were flowering; and in autumn, when the berries were ripe. It was found that the young roots contained only hyoscyamine; whilst the old roots contained besides much hyoscyamine a little atropine. The leaves of the ordinary wild-growing belladonna contained much hyoscyamine and a little atropine. The ripe berries contained only atropine.

—H. T. P.

*Investigations of Crude Acetone Boiling between the Temperatures of 75° and 135°.* L. Wolfes. Chem. Zeit. 14, 1141—1142.

THE material on which the following experiments were conducted was obtained from the works of Hofmann and Schötensack, Ludwigshafen. It was distilled, and the distillate collected in three fractions. The first portion contained a substance boiling at 80°, which gave a crystalline compound on being treated with sodium bisulphite; from repeated analyses, however, figures could not be obtained agreeing with the formula of methyl ethyl ketone. To purify it, it was treated with phenylhydrazine, and was found to give off a gas smelling strongly of ammonia. A second portion was combined with hydroxylamine, forming an oil boiling between 149° and 150°, which on analysis appeared to be the oxime of methyl ethyl ketone.

Second fraction.—By repeated distillation, a substance boiling at 102°—103° was next obtained, which possessed, approximately, the formula of methyl propyl ketone; this also gave with sodium bisulphite a white crystalline body, whose sulphur and sodium agreed closely with the ketone compound. With hydroxylamine it gave an oxime boiling at 167°. For its further identification, a fresh portion was oxidised with potassium permanganate, and the salts of the resulting acids converted into silver compounds; and owing to the different degree of solubility of silver acetate and propionate, it was found possible to purify each separately and identify them. That no diethyl ketone was present in this fraction was proved by the fact that the filtrate from the bisulphite precipitate contained no more oil.

Third fraction.—This portion was found to boil between 125° and 131°, and by repeated fractionation was split up into several fractions of about the same amount. Of these, the one boiling at 128°—129° gave on analysis figures midway between those of methyl butyl ketone and diallyl ketone. This fraction, partially combined with sodium bisulphite, and the oil, freed from its combination by means of sodium carbonate, gave an oxime boiling at 182°, which proved to be that of methyl butyl ketone. Another part oxidised with potassium permanganate, the potassium salts converted into free acids by means of sulphuric acid and extracted with ether, the butyric acid was found chiefly in the ethereal layer, the acetic acid being only dissolved in traces. From the ethereal layer, on the addition of silver nitrate, silver butyrate crystallised out, and from the aqueous, the acetate was obtained, thus proving distinctly that the substance in question was methyl butyl ketone.

The oils which gave no crystalline compound with sodium bisulphite were distilled with a strong solution of caustic soda, the distillate forming an oil boiling at 128°—130°, which, however, did not appear to be any definite compound. This was oxidised with nitric acid, evaporated to dryness, the residue dissolved in water, and neutralised with caustic baryta; the precipitate was filtered off, suspended in water, and decomposed by sulphuric acid. The barium sulphate being removed, the solution was extracted with ether, which on evaporation left small crystals of succinic acid. The filtrate from the caustic baryta precipitate was treated with sulphuric acid to remove the barium and the filtrate extracted with ether; the residue was then treated with zinc carbonate in the cold, and after filtration evaporated

to dryness. The dried residue was dissolved in water and the solution heated, whereupon zinc pyrotartrate separated out.

This formation of pyrotartaric acid from that portion of the oil which gives no crystalline precipitate with sodium bisulphite proves that there is a ketone present containing a closed chain, which is probably identical with the one described by Kane (Ber. 8, 1256) as dumasine.—F. H. L.

*Terpenes and Etheral Oils.* O. Wallach. Annalen, 259, 309—324. (Compare this Journal, 1889, 635 and 959.)

PINOL must be regarded as the first product formed by the oxidation of oil of turpentine with oxides of nitrogen; it is, therefore, always formed in the preparation of pinenitroschloride. It is an unsaturated compound and combines with bromine, yielding a readily crystalline dibromide of the composition  $C_{10}H_{16}OBr_2$ , which melts at 94°.

*Pinol acetate*,  $C_{10}H_{16}O(O.CO.CH_3)_2$ , is obtained, together with pinol and pinol glycol when the dibromide is warmed with sodium acetate, or better still, with silver acetate, in glacial acetic acid solution; it is purified by distillation under reduced pressure. It crystallises well from water, melts at 97°—98°, and boils at 127° under a pressure of 13 mm.

*Pinol glycol*,  $C_{10}H_{16}O(OH)_2$ , is best prepared by boiling the acetate with dilute sulphuric acid for several hours; the glycol is then partially extracted by shaking with chloroform, and the remainder is obtained in crystals by evaporating the solution. It separates from water in compact crystals, melts at 125°, and is converted into the acetate when it is boiled with acetic anhydride.

*Pinol hydrate*,  $C_{10}H_{16}O < \begin{smallmatrix} H \\ OH \end{smallmatrix}$ , can be obtained by dissolving crude pinol (loc. cit.) in its own weight of glacial acetic acid, saturating the well-cooled solution with hydrogen bromide, and then shaking it with excess of well-cooled, very dilute caustic soda; the mixture is then submitted to distillation with steam to free it from cymol, and the residual solution extracted with ether. It crystallises in plates or needles and melts at 131°. When an aqueous solution of pinol hydrate is warmed with dilute sulphuric acid it quickly becomes turbid, owing to the separation of an oil; this oil is chemically pure pinol.

Pinol hydrate is identical with the crystalline compound which is formed, as was first observed by Sobrero, when oil of turpentine is left in contact with oxygen in presence of direct sunlight.

It has been previously stated that pinol gives terebinic acid on oxidation with potassium permanganate; further experiments with pure pinol have confirmed this statement. Pinol hydrate, on the other hand, yields terpenylic acid on oxidation with potassium permanganate under the conditions previously described; pinol glycol seems to behave in a similar manner.

Pure pinol is easily obtained from pinol hydrate as stated above, but the method of preparation of the hydrate must be greatly improved before it can be conveniently employed for the preparation of large quantities of pinol. Pure pinol can also be obtained by heating a solution of the pure dibromide in dry benzene with the theoretical quantity of very fine sodium wire until the whole of the metal is converted into bromide; the filtered solution is evaporated and the residual pinol purified by fractional distillation.

*Pinol tribromide*,  $C_{10}H_{15}OBr_3$ , is obtained as a by-product in the preparation of the dibromide from crude pinol; it crystallises from ethyl acetate in needles, and melts at 160° with decomposition.—F. S. K.

*Fenchol, a New Substance Isomeric with Camphor.*

O. Wallach and F. Bartmann. Annalen, 259, 324—331.

WHEN oil of fennel is distilled a portion passes over between 190° and 193°, which has a strong odour of camphor and a specific gravity of 0.934 at 23°; this liquid

has the composition  $C_{10}H_{16}O$ , and, judging from its behaviour, the authors consider it to be a position-isomeride of camphor, to which they give the name *fenchol*.

Fenchol combines with bromine when treated therewith in well-cooled light petroleum solution, yielding a bright red crystalline powder which deliquesces on exposure to the air, and is reconverted into fenchol by caustic soda.

*Fenchol oxime*,  $C_{10}H_{15}N.OH$ , is formed when fenchol is treated with hydroxylamine in alcoholic solution; it crystallises from alcohol in needles, melts at  $148^{\circ}$ – $149^{\circ}$ , and combines with hydrogen chloride, yielding a crystalline salt, melting at  $118^{\circ}$ – $119^{\circ}$ . The *anhydride*,  $C_{10}H_{15}N$ , is obtained as an oil when the oxime is warmed with dilute sulphuric acid; it boils at  $217^{\circ}$ – $219^{\circ}$ , and in physical properties resembles the anhydride obtained from camphor oxime. The two compounds can, however, be distinguished by their behaviour with hydrobromic acid. When the anhydride of camphor oxime is shaken with a well-cooled glacial acetic acid solution of hydrogen bromide, and the mixture then poured into ice-cold water, there is precipitated an oil which does not solidify on cooling. The anhydride of fenchol oxime gives, under the same conditions, an oil which readily crystallises in the cold, the crystalline substance being the unstable hydrobromide,  $C_{10}H_{15}N.HBr$ .

*Isafenchol oxime*,  $C_{10}H_{15}NO$ , is obtained when fenchol oxime is boiled with alcoholic potash for 5–6 hours; it melts at  $113^{\circ}$ – $114^{\circ}$ , and is isomeric with the compound which is formed from camphor oxime anhydride in a similar manner. When the anhydride of fenchol oxime is boiled with alcoholic potash for four days it is converted into *fencholinic acid*,  $C_{10}H_{16}O_2$ , a compound which corresponds to campholinic acid,  $C_{10}H_{16}O_2$ ; it is a colourless liquid and boils at  $257^{\circ}$ – $260^{\circ}$ .

In physical properties fenchol and its derivatives differ to a not inconsiderable extent from camphor and its derivatives, as is seen from the following table:—

	Fenchol Series.	Camphor Series.
$C_{10}H_{16}O$ .....	Liquid; boiling point, $136^{\circ}$ – $135^{\circ}$ .	Solid; boiling point, $204^{\circ}$ .
Oxime, $C_{10}H_{15}N.OH$ .....	Melting point, $148^{\circ}$ – $149^{\circ}$ .	Melting point, $118^{\circ}$ .
Oxime hydrochloride.....	Melting point, $118^{\circ}$ – $119^{\circ}$ .	Melting point, $153^{\circ}$ – $154^{\circ}$ .
Oxime anhydride, $C_{10}H_{15}N$ ...	Boiling point, $217^{\circ}$ – $219^{\circ}$ .	Boiling point, $216^{\circ}$ – $217^{\circ}$ .
Iso-oxime, $C_{10}H_{15}NO$ .....	Melting point, $113^{\circ}$ – $114^{\circ}$ .	Melting point, $124^{\circ}$ – $125^{\circ}$ .
Acid, $C_{10}H_{16}O_2$ .....	Boiling point, $257^{\circ}$ – $260^{\circ}$ .	Boiling point, $254^{\circ}$ – $255^{\circ}$ .

In chemical behaviour, however, the two series of compounds show a very striking similarity, a fact which seems to show that fenchol and camphor differ from one another only in the relative position of the oxygen atom in the molecule.—F. S. K.

#### Oxidation of Potassium Cyanide with Permanganate.

J. Volhard. *Annalen*, **259**, 377–380.

When potassium cyanide is oxidised with potassium permanganate in the cold a large quantity of potassium cyanate is produced; this reaction, if carried out as described below, may be conveniently employed for the preparation of urea.

To a solution of 39 grms. of potassium cyanide and 10 grms. of potash in 100 cc. of water, a solution of 63 grms. of potassium permanganate in 1 litre of water is gradually added by means of a dropping funnel, the temperature being kept below  $17^{\circ}$ ; when ice is employed for cooling the mixture, the whole of the permanganate can be added in about half an hour, but it is more convenient to cool with running water, a current of air being at the same time passed through the cyanide solution. As soon

as the whole of the permanganate has been added the mixture is placed in cold water for about 7–8 hours until the green colouration has disappeared, then mixed with a concentrated solution of ammonium sulphate (70 grms.), boiled and filtered: the filtrate is evaporated and the urea extracted from the residue with boiling 95 per cent. alcohol. The average yield is 24 grms., or 68 per cent. of the theoretical quantity, but the urea obtained in this way still contains small quantities of chloride and sulphate of ammonium; it can be purified by treating its aqueous solution with freshly prepared barium carbonate, evaporating the filtrate to dryness, extracting the residue with absolute alcohol, and then recrystallising the product from alcohol.—F. S. K.

#### The Constitution of Carbonylorthamidophenol. O. Gressly and M. Nencki. *Monatsh.* **11**, 253–259.

The authors allude to the methods of obtaining this substance and its two isomeric ethyl derivatives, and describe their own experiments conducted with the view to decide between the two formulae—

Their method consists in examining the changes which carbonylorthamidophenol undergoes in the animal system as compared with other aromatic compounds. It is known, for instance, that acetanilide administered to the rabbit becomes oxidised to paramidophenol, the acetyl group being split off. In the dog the main product is the anhydride of hydroxyphenylcarbanic acid, and in the human system acetanilide is partly converted into acetyl-paramidophenol. In each case therefore a hydrogen atom in the benzene nucleus is oxidised to hydroxyl. Aromatic compounds containing a carboxyl group are on the other hand not oxidised in the animal system, whilst the homologues of benzene, the aromatic alcohols, aldehydes, &c. are oxidised to carboxylic acids. Hydroxy compounds, such as the phenols, suffer no oxidation. In the case of substances containing neither a carboxyl nor a hydroxyl group, and where no oxidation of a side-chain takes place as in benzene, indole and camphor, a hydrogen atom in the nucleus again becomes oxidised to hydroxyl, the products being phenol, indoxyl and camphorol. Arguing from these facts the authors conclude that if carbonylorthamidophenol contains an hydroxyl group as indicated by the formula—

it should not suffer oxidation in passing through the system, whilst on the other hand if its constitution be—

they would expect a hydrogen atom in the nucleus to become oxidised to hydroxyl, and the product discharged by the animal should be—

Their experiments made both on rabbits and dogs show the latter view to be the correct one, the carbonylorthoxyamidophenol being discharged in the form of sulphate—

—A. K. M.

*Combinations of Camphor with Phenols and their Derivatives.* E. Leger. *Compt. Rend.* **111**, 109—111.

CAMPHOR forms a series of real compounds with the phenols, which, however, owing to their instability and the ease with which the components are regenerated by the action of heat, alkalis or solvents, have been regarded as simple mixtures. Some of these can be obtained crystalline, others only in the liquid state; the latter are regarded as definite compounds, because: (1) they result by mixing molecular proportions of their constituents; (2) when crystallised by cold the successive batches of crystals obtained all have the same composition; and (3) the introduction of phenols into an alcoholic solution of camphor diminishes the rotatory power of the latter by almost one-half.

The following compounds, prepared by simply bringing together molecular proportions of camphor and the phenol have been prepared, and were analysed polarimetrically:—

Phenol forms two compounds, both liquids,  $C_6H_6O \cdot C_{10}H_{16}O$  and  $2 C_6H_6O \cdot C_{10}H_{16}O$ , the latter of which combines with another molecule of camphor to form the former. Two compounds were also obtained from resorcinol,  $C_6H_6O_2 \cdot C_{10}H_{16}O$  and  $C_6H_6O_2 \cdot 2 C_{10}H_{16}O$ ; the first of these is a solid, melting about  $23^\circ$ , the second a liquid.  $\alpha$ -naphthol forms the compound  $C_{10}H_7O \cdot C_{10}H_{16}O$ , and  $\beta$ -naphthol,  $3 C_{10}H_7O \cdot 5 C_{10}H_{16}O$ ; both of these are liquid. With salicylic acid, a body,  $C_7H_5O_3 \cdot 2 C_{10}H_{16}O$  results, which is crystalline and only slightly decomposed by water; it melts towards  $60^\circ$ . Salol also appears to form a compound with camphor. The rotatory power of these substances are given in the paper.—C. A. K.

*The Rotatory Power of Camphor in Solution in Various Oils.* P. Chabot. *Compt. Rend.* **111**, 231—233.

THE author has examined the rotatory power of camphor in solutions of olive oil (sp. gr. 0.9125 at  $19^\circ C.$ ), almond oil (sp. gr. 0.9173, at  $19^\circ C.$ ), and seed oil (sp. gr. 0.9233 at  $19^\circ C.$ ). The rotatory power of these solutions is nearly proportional to the quantity of camphor dissolved, so that if the percentage of this body in solution be represented by  $p$ , the rotation of the plane of polarisation (using a sodium flame),  $\alpha$ , in a 20 cm. tube, is for—

Olive oil.....	$\alpha = 10' + p \cdot 1' 1''$
Almond oil.....	$\alpha = p$
Seed oil.....	$\alpha = 36' + p$

From these values the proportions of camphor contained in saturated solutions of the three oils can be calculated. The following results were obtained in this manner:—

	Camphor.
	Per Cent.
Saturated solution of olive oil at $19^\circ C.$ .....	26.983
„ „ almond oil „.....	28.53
„ „ seed oil „.....	28.89

Taking account of the slight rotatory power of the oil, the molecular rotatory power for camphor in each of the three oils  $[\alpha]_D$  has been found to be:—

(1.) *Olive Oil*—

For a 3 per cent. solution...	$[\alpha]_D = 55^\circ 12'$
„ 20 „ „.....	$[\alpha]_D = 55^\circ 12'$

(2.) *Almond Oil*—

For a 3 per cent. solution....	$[\alpha]_D = 56^\circ 47'$
„ 20 „ „.....	$[\alpha]_D = 54^\circ 19'$

(3.) *Seed Oil*—

For a 3 per cent. solution....	$[\alpha]_D = 54^\circ 24'$
„ 20 „ „.....	$[\alpha]_D = 54^\circ 7'$

It appears therefore that the value  $[\alpha]_D$  varies little with the degree of dilution, but increases with the latter, whilst with other solutions of camphor the reverse is the case.

—C. A. K.

*The Localisation of the Principles which furnish the Sulphur Essences of the Cruciferae.* L. Guignard. *Compt. Rend.* **111**, 249—251.

THE author describes a series of investigations having for their object the tracing of the localities in cruciferous plants in which sulphur containing essences, such as mustard oil, result, and finds that the ferment (myrosine) and the glucoside (potassium myronate), from the mutual reaction of which the mustard oil results, are contained in distinct and easily recognisable cells in the various parts of the plants.

—C. A. K.

*The Purple produced by Purpurea lapillus.* A. Letellier. *Compt. Rend.* **111**, 307—309.

FROM the moment when the colouration appears, an alliaceous odour is noticeable, and chemists have been inclined to attribute this to the formation of allyl sulphide. The odour is obtained not only by exposing the substance of *Purpurea lapillus* itself to light, but also from the crystallised substance extracted from the same; the odour is, therefore, not due to putrefaction, but has for its origin true chemical change.

The author has succeeded in proving directly that the odour is due to allyl sulphide, though only very small quantities are formed.

Presence of a cyanide or sulphocyanide is also assured.

—T. L. B.

*Otto of Rose.* R. Blondel. *Les produits Odorants des Rosières*, Paris, 1889, and *Pharm. J.* 1890, July 5, 3—5.

THE most important centre of the production of otto of rose is in the region of the Balkan mountains, and includes about 150 villages situated in the two valleys of Toundja and Strema, affluents of the river Maritza. These two valleys run from west to east and lie between the Great Balkan chain on the north and the Svedna Gora mountains on the south, the extreme points where rose culture is carried on being Koprivchitza on the west and Twarditza on the east. The best otto is obtained on the southern slope of the Balkans. Here the climate is temperate, but the variations in temperature are sudden and frequent. The ground is sandy and porous, as a rule; where this is not the case, and water accumulates, roses are killed by the frost, or by fungi which attack the roots. Although the rose cultivation extends over a large tract of country, it is nowhere conducted on a large scale by any one individual, but is divided into a large number of small plots belonging to small proprietors. The dealers live in the towns, and although they sometimes buy the flowers and distil the oil, they rarely cultivate the roses, and then only to a small extent.

The roses are grown in long borders or plots 100 or 200 metres long, the plants attaining the height of a man. Between the plots a space of  $1\frac{1}{2}$  to 2 metres is left, so as to allow of a cart passing along between them.

Two roses are usually cultivated, a red and a white one, specimens of which, gathered in the Kejanlik plantations, have been identified by the author. The red one proved to be a branching form of *Rosa damascena*, and the white one *Rosa alba*.

The *Rosa alba* is employed to form a dividing line between the different plantations, and is also grown at the end of each plot, so as to present only roses of less value to the peasant, who would otherwise steal the more valuable red rose; it is not used, as a rule, for distillation. Dishonest cultivators, however, take advantage of the fact that when distilled it yields a product rich in stearoptene (although of poor fragrance), to mix it with the red rose, and thus obtain an otto which will bear dilution with Turkish oil of geranium (oil of *Andropogon schenanthus*, L.).

In May of the second year the rose trees are about 2 feet high and yield sufficient flowers to pay the expense of their cultivation up to that date. The next year they are in full bearing, and the maximum product is obtained when they are five years old, although the plants will live more than

20 years. At 10 years of age they are, however, usually cut level with the ground, new branches, and even flowers, appearing the next year.

The flowers commence to expand between May 20th and 28th, and they are collected daily till June 15th and 20th. The collection commences every day at dawn, for an opening flower-bud left till next day will then have lost its fragrance and its colour.

The contents of the baskets are weighed in the field, paid for and emptied into sacks, which are carried at once to the distillery. If the white roses are present in too large proportion they are paid for separately at a lower price. The stills are usually placed in sheds near the river, for the convenience of obtaining a good supply of water, and in some cases are let by the proprietors at the rate of 4 francs per still. The stills are of copper, and are made to contain 75 litres of water and 10 kilos. of flowers. The latter are introduced by means of an osier basket, and the stills are heated with long logs of wood lighted at one end, placed under the still. After a time, if steam comes out of the refrigerating tube, the fire is moderated, and when 10 kilos. (two flasks) of rose-water have distilled over, the fire is removed by withdrawing the burning logs. The still when cool is opened, the contents strained through the osier basket, and the water remaining in the stills saved for the next distillation. If the operation is continued until 15 kilos. of rose-water is obtained the otto is of inferior quality, and contains more stearoptene.

The rose-water is then submitted to distillation a second time, 40 litres being distilled at a time, and only 5 litres collected. The vessels in which it is received have the shape of a long necked flask, and the water is at first milky, like an emulsion, the oil floating after a time in the neck of the flask. It is removed by inserting a conical tin funnel about two centimetres long, furnished with a slender handle, and having a capillary orifice. It is dipped below the surface of the otto, and when a drop of oil on raising the funnel appears at the orifice it is emptied quickly into a special flask.

About 3,000 kilos. of flowers are calculated to yield a kilo. of otto, and this quantity of flowers is the usual yield per hectare, so that it may be considered that a hectare of roses yields a kilo. of otto. The adulteration of the otto takes place chiefly by the addition of oil of rose geranium (*Andropogon schenanthus*), whereby the congealing point is lowered from 15° or 16° R. to 14°, 13°, or 12°, and even lower. The purchaser of otto generally brings with him a basin and thermometer, and having obtained the desired temperature by mixing warm and cold water, and testing the temperature with the thermometer, inserts a flask containing 15 grms. of the essence to be tested. In about three minutes crystalline needles appear, and in 10 minutes the otto is solid enough for the uncorked flask to be reversed without spilling a drop. The price varies according to the degree of congealing point, that below 12° R. being openly sold at a special rate. The average production of otto of rose in Bulgaria is about 3,000 kilos. in good years, and 1,500 kilos. in bad ones.

The peasants are paid according to the season at the rate of .32 to .23 fr. per gramme for otto of standard purity. The flattened circular metal bottles in which it is exported contain 400 grms., 1 kilo. or 2½ kilos., and the price of the pure essence is 800 to 900 frs. per kilo., according to the season. The bottles are generally enveloped in felt. When the essence is freshly distilled it has a slight empyreumatic odour, possibly due to the fact that the water in the stills at the end of the day, having served for several distillations, has dissolved vegetable salts and boils at a temperature distinctly above the boiling point of pure distilled water. Otto of rose is also said to be produced in notable quantities in Asia Minor, at Broussa, Bourgas, and elsewhere by emigrants from Roumelia.

In Provence the cultivation of the roses is at the present time a flourishing industry, and the otto prepared in that district is considered superior to the Bulgarian product. It is obtained from *Rosa centifolia* (a specimen of the plant used from Grasse having been determined by Dr. Blondel). This rose flowers there in April and May. Rose-water is sometimes distilled from the yellowish tea rose known as

Safrano, which flowers in autumn and winter, but the water is very inferior, and the otto obtained from it is still more so, and unfit to mix with that of *R. centifolia*.

The cultivation of *Rosa centifolia* is carried on chiefly around Grasse, Cannes, Nice, and Valois, by peasant proprietors, who sell the flowers to the distillers in the towns. The chief use of the roses is for making rose pomade, only a small quantity, comparatively speaking, being distilled for the otto. The flowers are distilled in large stills, such as are generally used for spirit, some holding as much as 150 kilos. of flowers. Often one refrigerator receives the condensing pipes of several stills.

Usually 50 kilos. of flowers and 300 litres of water are placed in the still at one time, and 100 litres are distilled over, the first 25 being the richest in oil, and known as eau double de rose; the next 30 are of medium, and the remaining 45 of inferior quality. The oil which floats is collected by means of a florentine receiver. The yield of otto is small, 100,000 kilos. of flowers giving only a kilo. of otto, and the price is about 1,000 francs per litre; the average price of the rose-water is 2-60 francs per litre.

In Germany roses have been distilled for about five years in the neighbourhood of Leipzig, about six hectares being at present under cultivation. The species employed is *Rosa centifolia*, and the amount produced in 1887 was 3,000 litres of rose-water and 2 kilos. of otto. The latter congeals at 20° C., and contains 32½ to 34 per cent. of stearoptene, which is in excess of that in Bulgarian otto. Indeed the proportion of stearoptene present in otto of rose is always greater in cold countries.

Formerly otto of rose used to be adulterated by mixing it direct with oil of ginger grass, but now the flowers are sprinkled with the oil when placed in the retort. The odours under these circumstances amalgamate better, and during the distillation the proportion of waxy (cireuse) matter that passes over is larger, so that otto thus obtained may solidify at 14°, even when containing 25 per cent. of oil of ginger grass. In this case, however, the otto appears muddy, and does not present the sparkling crystals characteristic of pure otto. The odour also is easily detected by an expert. Bromine turns pure otto of rose of a green colour, but is itself decolourised by oil of ginger grass, and if a few drops of liquor potassæ are subsequently added, an apple-green precipitate in viscous clots is formed in a colourless liquid, and the odour of roses is not altered; but if adulterated with ginger-grass oil a yellow milky precipitate is obtained in a reddish liquid, and a disagreeable odour is given off. This test, however, is qualitative rather than quantitative.

The presence of spermaceti or paraffin in otto is detected in Bulgaria by rubbing the small test bottle of otto between the hands, containing about 15 grms., when the essence rapidly liquefies, since a temperature of 18° C. suffices, whereas paraffin does not melt till 32°—50° and spermaceti at 46° C., and these remain undissolved at the bottom of the bottle.

Experiments made by the author show that pure otto of rose has some physiological effect. In the dose of five or even of two drops it produced cramp of the stomach in the absence of food. Taken after a meal it seemed to stimulate the digestive functions at first, but doses of 10 or 12 drops appeared to have an opposite action, and caused marked flatulence. The only general effect noticed was a marked tendency to sleep. A guinea pig into which a cubic centimetre of otto was subcutaneously injected died in four days after a state of profound torpor lasting 48 hours. The only effect noticed in a post-mortem examination was a slight congestion of the meninges. In some persons the odour of the rose produces headache, and in rare cases severe symptoms, which are probably due to idiosyncrasy. The oil of *Andropogon schenanthus*, or Turkish oil of geranium, used to adulterate oil of roses, produces similar symptoms, but in a higher degree.

With regard to the portion of the flower in which the otto is formed, observations made under the microscope indicate that it is secreted by the epidermal cells. Other experiments show that these cells also contain fixed fatty matter, since when the petals are distilled until wholly deprived of odour, these epidermal cells are still blackened by osmic acid, and yield to ether a fixed fatty substance. But the fresh petals treated directly with ether, and thus

deprived both of fixed oil and essential oil, still show the blackened epidermal cells when treated with osmic acid, but with a bluer tint in them. This is due to tannin, as may be proved on a section of the fresh petal by the use of acetate of iron. When the petals are deprived of their essential oil by distillation of their tannin by boiling water, and their oil by ether, the epidermal cells no longer become blackened by osmic acid. There is, therefore, every reason to suppose that the chemical changes by which the otto is produced take place in the epidermal cells, or in other words that they are not special receptacles of secretion but secreting cells. The epidermis of the anther does not contain otto, but it is contained in small quantity in that of the filament and on the stigmatic surface and groove, though not in that of the ovary or style.

*Camphor in Florida.* Chemist and Druggist, November 29, 1890, 750.

At the October pharmaceutical meeting of the Philadelphia College of Pharmacy Professor Maisch gave an account of the prospective camphor-industry in Florida. It seems that the camphor tree grows in almost any kind of Florida soil, and is not affected by cold weather. At four years old the trees are 10 ft. high, and the trunk is 4 in. in diameter; at 10 years one tree was 35 ft. high, the trunk being 10 ft. long, and 1 ft. in diameter. Some of the branches, weighing 13 lb., yielded on distillation a teacupful of camphor, which was separated by cold from the oil which distilled over along with the steam. It is thought that in 10 years more camphor trees will be growing in Florida than orange trees, and that the industry will prove to be more profitable than the production of sugar. At the present time the price for camphor tree yearlings is from 25 to 50 cents. It is recommended that at the age of four or five years the first cutting should be made for distillation by pruning from the ground to the height at which the head of the tree is to be retained. From that time on, the head has to be sheared in a suitable manner, without neglecting the pruning from the ground up, with the view of making the head larger. With this treatment distillation would be carried on every year, and in 12 or 15 years the trunk of the tree will have attained a sufficient size to be sawn into timber, so that the valuable camphor-wood may also be utilised. The trees being set 15 ft. apart, the stumps may be allowed to produce shoots until young trees have been raised and are sufficiently advanced to take the place of the old ones, when the stumps are uprooted and subjected to distillation. According to Maisch, the camphor produced is of good quality, but the statement that it is stronger than Japanese camphor is erroneous. It is gratifying to know that a new source of camphor will thus be available, for at present it does not seem to be possible to get enough of it from China and Japan.

*The Apocynaceæ.* Chemist and Druggist, November 29, 1890, 750.

THE apocynaceæ have, during the last few years, yielded several new drugs to *matéria medica*, and naturally, therefore, physiologists give particular attention to this class of plants. But it must not be supposed that they are all poisons; some of them have comparatively mild physiological action. Quebracho, for instance, is used as a febrifuge and anti-asthmatic; *Alstonia scholaris* is the source of Dita bark employed in India, and recently in the United States, in chronic diarrhoea and dysentery. Some members of the order, such as *Alstonia* and *Vakea gumifera*, yield a substance resembling india-rubber, and used as such (especially the product of the latter-named plant) in France.

*Apocynum cannabinum*, which is a powerful emetic and purgative, takes precedence of the above-mentioned in point of intensity of therapeutical activity. Then we have *Wrightia antidysenterica*, containing "wrightine," identical with conessine; this has repute and is used as a cardiac. Further in the first rank there is *Nerium oleander*, and, of

course, *Strophanthus*, so well known in some respects, and yet—at least, as regards its botany and source—so little known.

Although only three years have passed since *strophanthus* became available for use in medicine, a number of apocynaceæ have been investigated, their active principles separated and physiologically examined. After *Strophanthus*, *Carissa schimperi* was worked on and found to contain ouabaine, which is now prepared from the so-called glabrous *strophanthus* seeds, and believed by some pharmacologists to be identical with strophanthidine.

Boehm then investigated *Adenium Boehmianum*, an ever-green shrub belonging to the same order; the milky juice of this plant is also used by the natives as an arrow-poison. Echujin was separated by Boehm and found to be a powerful heart-poison.

Recently a further link in the chain of apocynaceous drugs has been forged by Professor Kobert and his pupil, Minkiewicz, in the complete chemical and physiological investigation of *Urechites suberecta*. This West Indian climbing plant was first known under the name of *Echites neriantra*; the generic term (from the Greek *echis*=viper) was employed by Pliny for a twining plant. The plant, now termed as stated, *Urechites suberecta*, is known in South America, in the West Indies, and in Jamaica; a living plant was shown by Mr. Holmes at the recent *conferentia* of the Pharmaceutical Society, the exhibitor observing, with reference to its poisonous properties, that a native of Java would not accompany one of his brethren if he knew that the latter had some *urechites* leaves in his pocket.

The leaves of *Urechites suberecta* are dark green, oval somewhat acute, entire, petiolate, and opposite; the plant has large yellow flowers, the so-called savana flowers. The latter and all green parts of the plant have an intensely bitter taste, and the dry powder of the leaves affects the mucous membrane of the nose, producing sneezing. The milky juice of the plant is said to be used by some Indians to prepare the woorara poison.

A recent chemical examination by Kobert resulted in the separation of a glucoside, soluble in benzene, and of urechitic acid, insoluble in benzene, but taken up by amyl alcohol. This distinction was the basis of a process for separating the two principles. Urechitic acid, which seems to be a resin, is yielded in the proportion of 2 per cent., but only  $\frac{1}{2}$  per cent. of the glucoside is obtainable.

## XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

### PATENTS.

*An Improved Trough for Use in Washing Photographic Prints, Photographic Negatives, and the like.* P. Ellis, Wallington. Eng. Pat. 16,492, October 18, 1889. 8d.

A box of thin sheet metal is provided with a vertical rack for holding plates and a horizontal rack for holding prints, and is constructed of such a shape that when filled with water to a certain height, it tips over and empties itself, returning to its original position under the supply tap as soon as the greater part of its contents has been discharged. —C. H. B.

*A New or Improved Compound or Developer for Use in Photography.* B. Jumeaux, Manchester. Eng. Pat. 18,547, November 20, 1889. 4d.

Eikonogen, potassium chlorate, and sodium sulphite are slightly damped, mixed together and dissolved in hot water. The proportions given are eikonogen 2 drms., potassium chlorate  $1\frac{1}{2}$  drms., sodium sulphite 3 oz., water 20 oz., but

other proportions may be used, and other suitable potassium salts, such as the bromide, or sodium salts, such as the carbonate may also be added.

It is claimed that this developer is self-contained, requires no accelerator, develops negatives, lantern slides, opals, and paper prints, and, except after repeated use, does not stain either the photograph or the hands of the operator.

—C. H. B.

*An Improved Process or Means for giving a Matt Surface to Albumenised Silver, Paper, Photographs, or Prints.*  
J. B. Payne, London. From C. F. Binns, Wellington, New Zealand. Eng. Pat. 19,205, November 29, 1889. 6d.

A SHEET of finely ground glass, or a slab of marble, slate, or other material with a finely ground or matt surface is coated with a waxing compound prepared by dissolving 3 drms. of best bees' wax and 3 drms. of yellow resin in 1 pint of turpentine. In warm weather a greater proportion of resin must be used. The waxing compound is poured on the plate, which is then carefully polished, and allowed to dry for 24 hours in a place free from dust. The plate is next coated with a gelatin-zinc compound made by dissolving 2 oz. of Coigners or some similar gelatin in 20 oz. of water and adding zinc oxide and glycerol in proportion depending on the character of the zinc oxide. With the ordinary commercial zinc oxide, 1 oz. of glycerol and  $\frac{1}{2}$  oz. of the oxide are good proportions, but 50 grs. of Hubbard's oxide and  $\frac{1}{4}$  oz. of glycerol will be found sufficient. The glycerol and zinc oxide are carefully mixed in a mortar and are then incorporated with the gelatin solution, which is afterwards strained.

The waxed and polished plates are coated with the gelatin-zinc compound at a temperature not exceeding 130° F. if the plate is dipped into the solution, or 108° F. if the solution is poured on the plate. As soon as the gelatin has set the plate is placed face upwards on a stand, flooded with cold water, and carefully brushed with a camel's hair brush. It is again flooded with water, and the silver print, previously soaked in water, is placed upon it face downwards and carefully squeezed into perfect contact, the superfluous moisture being afterwards removed with a sponge. A backing of paper or other suitable material may be applied to the print, and the plate is set up to dry, which requires from 18 to 24 hours in summer weather. When perfectly dry, the print is removed by inserting a penknife between it and the plate. Gelatin alone may be used in place of the gelatin-zinc compound, but the zinc oxide gives a desirable "bloom" to the picture.—C. H. B.

## XXII.—EXPLOSIVES, MATCHES, Etc.

*On the Absorption of Carbonic Oxide by the Earth.*  
Berthelot. *Compt. Rend.* 111, 469—471.

DOUBTLESS carbonic oxide is the cause of many deaths after coal-mine explosions. It is produced in considerable quantities from certain explosives which are now extensively used, such as mellinite, gun-cotton, &c., and the author has investigated the question whether this gas (CO) is more readily retained by the soil than ordinary atmospheric air. Contrary to the assumption of certain witnesses this is not the case, the earth being able to absorb exactly the same amount of carbonic oxide as it does of air.—A. R.

## XXIII.—ANALYTICAL CHEMISTRY.

### APPARATUS.

*Metallic "Scrated Tubes."* H. Schiff. *Chem. Zeit.* 14, 1407—1408.

ENAMELLED iron tubes, closed by a screw-plug, have been recommended, for laboratory purposes, to take the place of sealed glass tubes. In practice it is found that the enamel soon cracks off, and that the thread of the screw-plug rapidly wears out. The author has devised an apparatus in which these difficulties are avoided. It consists of a cast-bronze tube, open at one end, having an internal diameter of 36 mm. and a length of 330 mm. The walls of the tube are 8 mm. and the bottom 10 mm. in thickness. The lid—10 mm. in thickness—fits on the open end of the tube, and is held down by a screw clamp, the screw of which works in a slight depression in the centre of the lid. The jaws of the clamp are slipped under the projecting rim (14 mm. wide) of the tube. The tube is hermetically sealed by placing between the top of the tube and its lid, a disc of paper soaked in water or other suitable liquid. A glass tube sealed at one end and contracted at the other to a diameter of 12—14 mm., fits tightly inside the bronze digester, and is of such length that its open end reaches within 3—4 mm. of the lid when screwed down, the intervening space being filled by a disc of asbestos fitting moderately tight.

According to the author's experience, these tubes are but slightly attacked by the vapours of hydrochloric and hydrobromic acids, and of ammonia. Hydriodic acid gas attacks them to a greater extent; but operations with alkaline iodides may be safely carried on in such tubes. Sulphuretted hydrogen and ammonium sulphide strongly corrode the metal.

The author also describes a larger form of digester of  $1\frac{1}{2}$  litres capacity, similar in principle to the above.

—H. T. P.

### INORGANIC CHEMISTRY.

#### QUANTITATIVE.

*Experiments on the Quantitative Determination of Arsenic by Marsh's Method.* B. Kühn and O. Saeger. *Ber.* 23, 1798—1803.

POLENSKE showed that small quantities of arsenious acid can be almost completely converted into arseniuretted hydrogen, and this latter into metallic arsenic. But Polenske could not convert more than 0.005 grm. of arsenious acid into metallic arsenic. He now shows that larger quantities can also be converted into metallic arsenic. The experiments were made as follows:—150 grms. of pure granulated zinc were put into an Erlenmeyer flask of 400 cc. capacity, and the flask closed by a doubly-perforated india-rubber stopper. Through one perforation passes a funnel tube reaching nearly to the bottom of the flask, through the other an outlet tube, bent at right angles. The latter is connected with a wash-bottle, containing 50 cc. of a 5 per cent. lead acetate solution, to absorb sulphuretted hydrogen, if present. There is next arranged a system of drying tubes containing altogether at least 100 grms. of calcium chloride, and the last of these is connected with a combustion tube, open at both ends, 165 cm. in length and 10 to 12 mm. in diameter. The middle part of this tube rests in a combustion furnace 80 cm. long, both ends of 25 and 60 cm. length respectively are drawn out to a diameter of 5 mm. inside. The shorter end (of 25 cm.) is connected with the calcium chloride tubes, and the longer one with a silver nitrate solution of 3 per cent. strength. The furnace is heated by 24 Bunsen burners. Two burettes are placed above the funnel tube of the Erlenmeyer flask, one of them containing dilute sulphuric acid (1 part of sulphuric acid of 1.84 sp. gr. to 3 of water), and the other the liquid to be tested.

After the development of hydrogen has commenced, and after all air is expelled from the apparatus, the tube is heated to redness. If after half an hour's heating no arsenic mirror is obtained at the end of the tube, the reagents can be considered as pure. Then this last part of

the tube is also heated by three Bunsen burners, 15 cm. distant from each other, and the liquid to be tested is introduced from the burette into the Erlenmeyer flask drop by drop. Care must be taken that the liberation of hydrogen is always regular. Such regular liberation is effected by adding the sulphuric acid drop by drop (about 0.75 cc. per minute). After some minutes an arsenic mirror can be observed at that part of the tube away from the furnace. Should traces of mirrors appear also between the Bunsen burners placed there, or at the end of the tube, the hydrogen current is too strong, and must be diminished. After one hour all the liquid to be tested (25 cc.) will have been added, and the reaction with the course of operations are continued for two hours more, after which time the presence of arsenic is tested for by heating the tube just where it enters the furnace. If no arsenic mirror is observed the process is complete; in the other case, it has to be continued until no more arsenic is discoverable. When different small arsenic mirrors have been obtained, they are united to the large one, and the latter is cut out, dried, and weighed. Then the arsenic is dissolved in nitric acid, the empty tube weighed again, the difference indicating the amount of arsenic. When it is of importance to retain the arsenic mirror, the small tube is put into a larger combustion tube of about 50 cm. length, one end of which is drawn out. By heating in a current of hydrogen, the mirror is driven forwards to the larger tube, and the small tube is weighed when empty. Nos. I. and II. of the following tests were made with pure arsenious acid, obtained by sublimation. 25 cc. of the solution contained 0.1105 gm. of arsenious acid, equivalent to 0.0837 gm. of arsenic. Nos. III. and IV. were obtained by using potassium arsenate, which was converted into magnesium arsenate (pyro salt), and thus weighed.

From 25 cc. of potassium arsenate were obtained 0.1907 gm. of  $Mg_2As_2O_7$ , equivalent to 0.09227 gm. of As. The different tests gave the following results:—

Nos.	Arsenic employed.	Arsenic obtained.	Difference.
	Gm.	Gm.	Gm.
I.	0.0837	0.081	0.0027
II.	0.0837	0.0832	0.0005
III.	0.09227	0.0911	0.00117
IV.	0.09227	0.0907	0.00157

The authors have further found that arseniuretted hydrogen is decomposed by caustic potash, a fact not generally known. This was ascertained by introducing into the apparatus described, a tube containing dry caustic potash between the last of the calcium chloride tubes and the glass tube which was to be heated. The following results were thus obtained:—

Nos.	KHO used.	Arsenic employed.	Arsenic obtained.	Difference.
	Grms.	Gm.	Gm.	Gm.
I.	25	0.0837	0.0760	0.0077
II.	100	0.0837	0.0732	0.0105

In a subsequent test in which 225 grms. of caustic potash were used, 0.0573 gm. of the arsenic mirror obtained in the last experiment (No. II.) were converted into potassium arsenate and dissolved in 25 cc. of water. The result of the test was as follows:—

Arsenic employed.	Arsenic obtained.	Difference.
Gm. 0.0573	Gm. 0.0316	Gm. 0.0257

The presence of arsenic in the caustic potash tube was easily ascertained by the blowpipe reaction.—H. S.

*Quantitative Determination of Antimony by Marsh's Method.* A van. Bylet. Ber. **23**, 2968—2971.

The method is adapted to the estimation of small quantities of antimony in antimony alloys. The alloy is dissolved in mercury, and to the solution sodium amalgam is added to form the sodium antimonide. This is then decomposed by means of dilute sulphuric acid. The apparatus necessary consists of a three-necked Woulff's bottle, one neck of which is connected with a carbon dioxide generator; through the middle neck passes a feed tube, which should be as wide as is compatible with the size of the neck, and the third neck has attached to it a calcium chloride tube and a piece of glass combustion tubing. 0.5 gm. of the alloy is dissolved in 20 cc. of mercury by warming in a test tube to 60° C. After cooling the amalgam is introduced into the Woulff's bottle and the central tube is made to dip under its surface. Through one of the side necks 100 cc. of sulphuric acid (1 to 10) are added. The air is now displaced by carbon dioxide, the combustion tube heated to redness, and sodium amalgam (made by dissolving 5.5 grms. of sodium in 25 cc. of mercury) added drop by drop down the central tube. The apparatus is carefully shaken, care being taken that no possibility of an escape from the central tube shall occur. When the evolution of gas has ceased, carbon dioxide is passed for some time, and then the heating of the tube is discontinued. Evolution of gas lasts usually about an hour. After this the supernatant liquid is removed and the mercurial solution is poured off and dried by filter paper. After the apparatus has been thoroughly cleansed and dried, one half of the mercurial solution is re-introduced, with 75 cc. of sulphuric acid (1 to 10); to the other half 3 grms. of sodium are added and this mixture is then poured drop by drop through the central tube to the first half. The antimony from this second experiment is collected in a fresh tube; it should not exceed 1 per cent. of the total antimony. The weight of antimony is ascertained by weighing the tubes.

To prevent the possibility of a deposit of carbon near the heated portion of the tube, a current of hydrogen may be employed instead of carbon dioxide.—T. L. B.

*The Estimation of Metallic Zinc in Zinc-Dust.* W. Minor. Chem. Zeit. **14**, 1142.

DREWSEN (Zeits. Anal. Chem. **19**, 50; this Journal, 1887, 147) has described a method which depends on the fact that finely divided zinc reduces a solution of chromic acid without evolution of hydrogen. The following modification of his process will be found to give exact results:—

The following solutions are required:—About 30 grms. of pure potassium bichromate dissolved in water, and made up to 1 litre. A solution of ammonio-ferrous sulphate, made by dissolving 150 grms. of ferrous sulphate, and 75 grms. of ammonium sulphate in water, adding 100 cc. of strong sulphuric acid and diluting to 1 litre. The bichromate solution is standardised by means of chemically pure zinc dust, and since this is difficult to obtain, even in the case of the electrolytic product, it is advisable to prepare it by filing down a rod of the pure metal by means of a hard file. The iron in the zinc so obtained should be estimated, but it will probably not exceed a few thousandths per cent., and may consequently be neglected. The ferrous solution is compared with the bichromate, using potassium ferrieyanide as the indicator. 1 gm. of the pure zinc is then treated with 60 cc. of bichromate, diluted with water, and about 20 cc. of dilute sulphuric acid added drop by drop from a burette, the addition being so regulated as to occupy about 20 minutes. More acid is then added and the excess of bichromate estimated by the ferrous solution. For the analysis of a sample of zinc-dust, the operation is conducted in the same way, the metal present being in proportion to the amount of bichromate reduced, compared with the quantity used in standardising on the pure metal.

The figure so obtained includes the amount of cadmium and iron reckoned as zinc, and when, as is usually the case, the zinc-dust is to be used as a reducing agent, this is immaterial, those metals acting like the zinc. A method of

calculation is given with a suitable practical illustration, showing how the exact amount of zinc may be determined. (See also this Journal, 1890, 109, 417, 554, 769, and 968.)

—F. H. L.

*The Dry Assay of Tin Ores.* Part II. H. O. Hofman. Technology (quarterly), 3, 261—280.

THE author describes further test assays of black tin-stone by other methods (this Journal, 1890, 899). Winkler's method gave results averaging 65·96 per cent. or 1·88 per cent. too low, the figures disagreeing amongst themselves to over 3 per cent. The process consists of reducing together 5 grms. each of cassiterite and cupric oxide with 15 grms. of black flux, 1·25 grms. of borax, and a little salt as a cover. A similar experiment is conducted without the cassiterite, and the copper obtained in the one case deducted from the alloy in the other gives the amount of tin. The following modifications of this method were tried: increasing the amount of charcoal; using chalk-lined crucibles; omitting the salt and increasing the potassium carbonate; and Ricketts' modification of adding argol; but they all gave worse, and in some instances very variable, results.

The iron method—reduction with hematite, charcoal, and potassium cyanide or fluorspar—gave unsatisfactory results. The same may be said when a mixture of ferrocyanide and cyanide was used, and also when any of the Cornish methods were employed. So far, with fairly pure cassiterite, only two methods have proved satisfactory, viz., the German and the pure cyanide methods. The author now attempted to prove which of these two methods gives the best results when the cassiterite is mixed with those minerals likely to be naturally associated with it. The minerals used were quartz, felspar, mica, tourmaline, garnet, and columbite. Mixtures of the purified cassiterite ore with varying proportions of each of these minerals were assayed by both methods, the percentage of tin being calculated on the cassiterite ore present. The charges were so regulated that the flux in the German assay was always equal to three times the quantity of ore plus the mineral, and in the cyanide assay to six times the quantity. In the latter case four parts of cyanide were mixed with the ore, one part was used to coat the crucible bottom, and one part as a cover. In all cases the cyanide method gave more concordant and less prejudicially affected results than the other. The results of the German assays fluctuated greatly as the amount of mineral present increased. Thus, in the case of quartz and albite the results were lower as the quantity of mineral was increased, the respective figures being, with 37·5 per cent. of each mineral, 60·7 and 60·2 per cent.; the corresponding cyanide figures being 63·90 and 65·30 per cent. (the real percentage of tin was 67·84). The tin buttons, moreover, in the German assay with albite contained iron, while those by the cyanide process were free, the temperature of fusion being too low to cause decomposition of the albite.

With muscovite, tourmaline, garnet, and columbite, the results with the German method were very unreliable, being sometimes too high and very ferruginous, and sometimes too low, varying from 82 per cent. with 50 per cent. of garnet to 46 per cent. with 44 per cent. of tourmaline. The cyanide method gave fairly good results in all the above cases, very little iron getting into the buttons except in the case of garnet, when the result was 69·89 per cent., with 37·5 per cent. of mineral present. With the same quantity of muscovite, tourmaline, and columbite the assays were respectively 63·3, 64·7, and 66·0 per cent. Consequently where anything like a true result is required the cyanide assay is by far the most to be relied upon and should be employed in cases of buying and selling, although in concentration works, where comparative results and large numbers of assays are required, the question of cost must be considered, and the cheaper German method might satisfactorily be adopted.

The author emphasises the importance of properly preparing the ore for assay, and states that the ordinary method of grinding the whole sample to a uniform size is not suited to the tin ores of the Black Hills, chiefly on

account of the preponderance of mica. Hence a preliminary sizing is advantageous. The ore while being pulverised is screened through a series of sieves, Nos. 20, 40, 60, and 80, the different sized screenings being then washed separately and the concentrates afterwards mixed, dried, passed through a 60-mesh sieve and again washed. This method gives purer concentrates and necessitates less loss of cassiterite as the material has been washed without excessive grinding, which in the present process reduces the brittle cassiterite to a slime, while some of the harder associated minerals are only converted into sands. The subsequent treatment of the concentrates mentioned in the first part of the paper is recommended, as the roasting renders the cassiterite more friable and more readily reducible, the assays in some cases showing a difference of 0·5 per cent. between the raw and roasted ores in favour of the latter.

—A. W.

*The Estimation of Nitrates in Manures by Reduction of the Nitric Acid to Ammonia.* T. F. Schmitt. Chem. Zeit. 14, 1410—1411.

THE reduction of nitrates to ammonia is rapidly effected in the following manner: 40 cc. of glacial acetic acid are placed in an Erlenmeyer flask of 750 cc. capacity, and 15 grms. of a mixture of equal parts of zinc dust and iron filings are added. 50 cc. of the nitrate solution, containing 0·5 gm. substance are next added, and the mixture is thoroughly shaken. The evolution of hydrogen, which at once commences, continues for about 15 minutes, when another 15 grms. of the metallic mixture must be added. At this stage the mixture sometimes becomes pasty; if so, an addition of 30 cc. of water must be made. After 30—40 minutes the reduction is complete. The mixture is rendered alkaline by adding 200 cc. of a sodium hydrate solution of 1·25 sp. gr., and the ammonia is distilled off in the usual way. The test analyses are exceedingly satisfactory. This method probably might be substituted for Jodlbauer's modification of Kjeldahl's process, the substance under examination being first reduced and then boiled with strong sulphuric acid.—H. T. P.

*The Division of Sulphuretted Hydrogen between the Metals of two Soluble Salts.* G. Chesneau. Compt. Rend. 111, 269—271.

WHEN sulphuretted hydrogen is added to a mixture of the nitrates of lead and copper in molecular proportions, in insufficient quantity to precipitate the whole of the two metals, the two metals are precipitated approximately in the ratio represented by the heats of formation of their monosulphides. This ratio decreases with an increase in the number of equivalents of hydrogen sulphide present; it also varies with the length of time the precipitate is allowed to stand. The ratio Cu:Pb after immediate precipitation was found in two cases to be 1·74 and 2·20 respectively; this decreased a little at first, being 1·61 and 1·88 after allowing the precipitate to stand for 5 minutes before filtering, but after 15 minutes standing in the first case and after 10 minutes in the second, the ratio began to increase again, and after three days had reached 20·20, and after 38 days 23·10. It appears from this that the nitric acid liberated by the sulphuretted hydrogen acts gradually upon the sulphides and redissolves them.

—C. A. K.

*Direct Determination of Total Acidity in Aluminium Salts.* H. Heidenhain. Pharm. Rundschau, 8, 189.

AS is well known alumina is not precipitated by alkalis in presence of tartrates. The question is, whether in such solutions the alumina still plays the part of a base, or whether it is indifferent, or acts as an acid. By using phenolphthalein as indicator it was found that alumina in presence of small quantities of a tartrate has a weak alkaline reaction, whilst in presence of a comparatively large quantity of a tartrate it was almost without action, and that further,

the alkaline character was more noticeable in the hot than in the cold. The following method thus serves for determination of total acidity in aluminium salts: The salt is dissolved in water, and for every part of  $Al_2O_3$ , 100–200 times the quantity of sodium potassium tartrate is added; after addition of phenolphthalein solution so much of a standard solution is added that a portion of the acid remains unsaturated. The whole is boiled to drive off any carbon dioxide, and after cooling titration is completed. The end reaction is not quite sharp, but is sufficiently so, since the error is not over 0.1–0.2 per cent. of the volume of standard solution used.—T. L. B.

### ORGANIC CHEMISTRY.—QUALITATIVE.

*Detection of Impurities in Alcohol.* E. Mohler. Compt. Rend, **111**, 187–190.

A NUMBER of reagents have been proposed at various times for testing the purity of alcohol; the action of such reagents has been examined in the present memoir.

Solutions of alcohol, 50°, were made up containing 0.1 per cent. of the various impurities contained in alcohol, and on such solutions the action of the reagents was tried.

**Sulphuric Acid.**—The maximum proportion of acid that should be used is 10 cc. of acid to 10 cc. of alcohol. With larger quantities, even pure alcohol becomes coloured; and with smaller quantities the delicacy of the reaction diminishes very rapidly. The solutions containing butyl aldehyde, acetone, propyl, isopropyl, normal butyl and methyl alcohols, ethyl acetate, and many other substances, showed no colouration.

**Rosaniline Bisulphite.**—The relative proportion of sulphuric acid to sodium bisulphite in the reagent exercises a great influence on the delicacy of the reaction. With little acid the reagent is coloured by pure alcohol, whilst if much acid be present, 0.1 per cent. of ethyl aldehyde produces no colouration. If the reagent be made up as follows, it is not affected by pure alcohol, and 0.001 per cent. of aldehyde may be detected by its means:—

	Cc.
Solution of magenta, $\frac{1}{1000}$ .....	30
Bisulphite of soda of 34° B.....	20
Sulphuric acid .....	3
Distilled water .....	200

The reagent should be used immediately after making up, and in the proportion of 4 cc. to 10 cc. of alcohol.

**Aniline Acetate.**—This is the reagent for furfural. The colouration produced is not largely influenced by the relation between the acetic acid and the aniline. The proportion of 10 drops of aniline to 2 cc. of glacial acetic acid gives the best results; the maximum of colouration is attained after about half an hour. The reaction is extremely delicate.

**Potassium Permanganate.**—In acid solution decolourisation was effected by paraldehyde, isobutyl alcohol, and isobutyl aldehyde. The reduction is in proportion to the amount of aldehyde present, and is independent of the concentration of the alcohol or the degree of acidity of the liquid.—T. L. B.

*Reactions of Salts of the Alkaloids.* A. Colson. Compt. Rend, **111**, 266–268.

PIPERIDINE precipitates the soluble salts of calcium, although the heat of formation of piperidine hydrochloride in aqueous solution is 13 calories, whilst that of calcium chloride is 14 calories. Similarly aniline and hydrochloric acid combine in aqueous solution with the evolution of 7.4 calories, whilst pyridine under the same conditions evolves 5.2 calories. The heats of formation of aniline and pyridine hydrochlorides (taking the base as liquid, the hydrochloric acid as gas, and the resulting salt as solid) are respectively 27.3 and 24.9 calories, but still pyridine

decomposes aniline hydrochloride in solution. The toluidines and other aniline bases furnish similar instances of such endothermic decompositions.

These apparently abnormal reactions are quite in accordance with Berthollet's laws, their occurrence being due to the differences in the heats of solution of the various salts referred to.

Piperidine hydrochloride absorbs 0.98–1.02 calories; aniline hydrochloride absorbs 2.66–2.73 calories; whilst pyridine hydrochloride evolves 0.1–0.15 calories, when dissolved in water.—C. A. K.

*The Presence of Furfuraldehyde (Furfural) in Commercial Alcohols.* L. Lindet. Compt. Rend. **111**, 236–238.

FURFURALDEHYDE forms an accidental impurity in commercial alcohols, and is not a normal constituent of the same.

Whenever the alcohol has been distilled over a naked fire or whenever the wort has been treated with acid, furfuraldehyde is found to be present, but when this latter condition has not been fulfilled, or when the alcohol has been distilled by steam, there is no furfuraldehyde formed. A sample of alcohol distilled over a naked flame was found to contain 0.2 cc. per litre of furfuraldehyde and various liqueurs prepared under like conditions from 0.02–0.40 cc. per litre, of this impurity. Its formation is probably to be traced to the decomposition of vegetable debris contained in suspension in the liquid during the distillation.

Where the saccharification of the cereals had been effected by means of mineral acids, 0.06–0.10 cc. of furfuraldehyde per litre was found in the resulting alcohols; the spirit in these cases was distilled by steam. In this case the impurity was shown by direct experiment to result from the action of the acid on the entire of the grain.

A small quantity of furfuraldehyde (0.01 cc. per litre of alcohol) was also found when the saccharification had been effected by means of diastase; its production in this case is traced to a preliminary lactic fermentation, the lactic acid acting in a similar manner though to a less extent than the mineral acids. Spirit obtained from beetroot, potatoes, and Jerusalem artichokes prepared under conditions so as not to produce furfuraldehyde, as indicated above, were found not to contain a trace of the impurity. Four samples of spirit obtained from molasses were found to contain from 0.04–0.05 cc. of furfuraldehyde per litre of alcohol; in this case the latter does not result from the action of mineral acids upon the sugar, but by the employment of a wort for the fermentation of the molasses which had been prepared by means of mineral acids.

In these experiments the acetate of aniline reaction with furfuraldehyde was employed both for the qualitative and quantitative determination of this substance (see also this Journal, 1889, 734).—C. A. K.

*A Characteristic Reaction of Cocaine.* F. da Silva. Compt. Rend. **111**, 348–349.

A SMALL portion of cocaine or of one of its salts is treated in the solid state with a few drops of fuming nitric acid.

After evaporation to dryness one or two drops of a concentrated alcoholic solution of potash are added, and the whole is well stirred. Presence of cocaine is evidenced by a distinctive odour reminding of peppermint. The test is said to be very delicate.—T. L. B.

*Examination of Olein for Resin.* G. Meyer. Chem. Zeit. **14**, 1202.

THE resin may best be qualitatively recognised by saponifying and salting out; resin soap is incompletely precipitated, or not precipitated at all. The amount of resin may be approximately estimated by a determination of the specific gravity, by polarisation, and by means of the acid value determination. Such means as these may also be adopted for recognising the presence of resin in soap.—T. L. B.

*Examination of Fats, Meats, &c.* G. Meyer. Chem. Zeit. **14**, 1202.

HORSE fat absorbs much more bromine than beef-fat and lard. Determination of bromine absorption may therefore lead in many cases to detection of the use of horse-fat in preparations.—T. L. B.

*Distinction between Genuine and Imitation Parchment Paper.* E. Muth. Dingl. Polyt. J. **277**, 360–361.

STEEPED in strong lime water, the material retains its white colour if made of cotton fibre, but turns yellow or brownish yellow if made of sulphite cellulose. Since mechanical wood-pulp also shows the latter change of colour, its absence should first be ascertained by the aniline sulphate or phloroglucinol reaction. The test is thus only applicable when mechanical wood-pulp is absent.—H. S.

## ORGANIC CHEMISTRY.—QUANTITATIVE.

*Percentage of Cellulose in Wood.* Papier Zeit.; and Chem. Trade J. 1890, **7**, 335.

THE method of analysis employed is as follows:—The wood under investigation is broken or cut into small pieces and then ground by rubbing in a mill. From 3 to 5 grms. of the ground wood are weighed off, dried at 100° C. till the weight is constant, and the percentage of water calculated from the loss in weight. The dry ground wood is then boiled in water, and afterwards digested in ether, the residue separated from the ethereal solution and dried. It is now digested with 3 to 5 grms. of caustic alkali, dissolved in 50 cc. of water in a small pressure flask placed in a paraffin bath to 130°–150° C. (preferably 135° C.), for two hours, or in some cases longer. If properly screwed up the small flask stands the pressure completely. It is allowed to cool in the paraffin bath, then opened, water added to its contents, and the brown lye separated from the insoluble matter by filtration and subsequent washing with water. The wood, or more properly speaking the cellulose powder, is now heated with an aqueous solution of bromine, and washed. Instead of this, an alkaline solution of bromine may also be used. The bromine acts upon the ligneous residue in the same way as chlorine. The cellulose is heated with ammonia water, again filtered and washed. If its colour be changed to brown on the addition of the ammonia, incrusting materials are still present, and the cellulose must again be repeatedly treated with bromine water and ammonia till it is pure white, and the ammoniacal filtrate is perfectly clear and colourless. In this way completely pure white cellulose is obtained, which is washed many times with water and with alcohol, and finally dried at 100° C. and weighed. By this method, in the preliminary treatment with water, colouring matters and mineral substances are removed. In the treatment with potash lye the greater part of the incrusting substances are removed and the bulk of the colouring matter, and finally, by first oxidising the incrusting substances remaining with the pure cellulose, with bromine, these are removed in the soluble form by ammonia.

*Prunus Padus (Bird Cherry Tree)*—The charcoal made from this tree is used for the manufacture of gunpowder. The raw wood is coloured yellowish and reddish. When boiled in water it assumes a grey colour, whilst the aqueous solution is reddish. The ethereal extract was yellow, the alkaline fluid red, while the remaining cellulose still retained a considerable reddish hue. Bromine water and ammonia at first turned the cellulose a light yellow, finally, however, a pure white. The yield on the air-dried wood was 40.98 per cent. of cellulose.

*Peruvia Wood.*—Dark red chips. The aqueous solution was red, the alkaline lye black red. With bromine water the cellulose appeared yellowish white, with ammonia colourless. On the air-dried wood it yielded 39.63 per cent. of cellulose.

Recent investigations seem to show that the sulphite method of estimating the amount of cellulose in wood is more correct than the caustic alkali methods. By digesting wood in caustic alkalis at high temperatures some of the cellulose ( $C_6H_{10}O_5$ ) passes into solution, or is dissolved, and is, of course, lost in the determination, and consequently a low result is obtained. Instead of using caustic alkalis, bisulphite of soda or potash may be employed for all those kinds of wood that are rendered soft by the bisulphite liquors, and whose incrusting and resinous materials are completely dissolved by them. On the other hand for oak and similar hard timbers the bisulphite process is useless.

*Ebony.*—The quantitative determination of the cellulose in this wood was impossible. It is, however, interesting to know that by the method just described, the deep black ebony wood yielded a pure white cellulose.

*A Quantitative Reaction for Lignin.* R. Benedikt and M. Bamberger. Monatsh. **11**, 260–267.

THE authors describe a number of experiments by which they have determined the methyl numbers of several kinds of wood, the experiments being a continuation of those on the ethereal oils (Chem. Zeit. **13**, 872 and 1087; this Journal, 1890, 735 and 925) and resins (Monatsh. **11**, 84; this Journal, 1890, 659).

Forty grms. of the wood shavings dried at 100° were put into the flask A together with 500 cc. of hydriodic acid of specific gravity 1.7, and containing 8 per cent. of acetic anhydride. Heat was applied and the distillation of the methyl iodide produced was regulated by adjusting the temperature of the water in B. The distillate which collected in D proved

be nearly pure methyl iodide; it amounted to 4 grms., i.e., 10 per cent. of the weight of the dry wood, but this does not represent the whole of the methyl iodide produced, as the apparatus remained full of vapour and part was no doubt lost. In the methoxyl determination (this Journal, 1889, 735) the methyl number obtained was 26.2, corresponding to 24.8 per cent. of methyl iodide.

Pure cellulose yielded no methyl iodide when boiled with hydriodic acid. On the other hand various woods which were boiled with water, dried, and then extracted for days first with alcohol and then with ether, were found to give the same methyl number as the same woods when not so treated. From these results it is concluded that *lignin* is the constituent of the wood to which the methyl number is to be ascribed.

Assuming the correctness of Schulze's determination of the percentage of lignin in oak, namely 54.4 (Chem. Centr. 1857, 321), the authors are able to calculate from the methyl number of the same wood, namely, 28.6, that lignin should have the methyl number 52.9, and from this they also calculate the percentage of lignin in various woods:—

	Methyl Number.	Percentage Lignin.	
		Benedikt and Bamberger.	Schulze.
Walnut shell .....	37.4	70.0	65.9
Holm-oak .....	28.6	54.1	54.1
Alder.....	28.9	54.6	52.0
White beech.....	26.4	49.9	51.6
Aescia.....	24.2	45.9	47.0
Pine.....	21.3	40.3	42.0

The paper concludes with a table showing the methyl numbers obtained with a number of different woods and other substances. The woods examined gave methyl numbers varying from 20 to 31. The older wood near the centre of a stem is shown to contain more lignin than the later rings, and the wood of a branch is richer in lignin than that of the stem. A comparison of the results obtained from lignite, peat and coal shows that the first has a methyl number corresponding with the woods, namely, 24.4, whilst that given by peat is 2.7, coal, on the other hand, yielding no methyl iodide when boiled with hydriodic acid.

—A. K. M.

*Determination of Tannin in Barks, &c.* G. Meyer. Chem. Zeit. 14, 1202.

Precipitation with acetate of copper gives good results, if the precipitation be performed in the hot, and if filtration and washing with hot water follow immediately; the precipitate is dried at 110°, weighed and ashed. From the total precipitate four-fifths of the weight of the copper oxide is deducted. Total tannin is thus ascertained. All bark extracts, however, contain both tannic acid and gallic acid with hydration products of the latter, and the value of the material is judged from the tannin matter precipitable by gelatin. This precipitable tannin may be determined by the method of Davy and Müller as follows:—The extract is prepared by digesting 20 grms. of bark once with 200 cc. of hot water, and five times with 160 cc. of hot water in a water-bath, each time for a quarter of an hour. The whole decoction is filtered and the filtrate is diluted to 1 litre. A solution containing 1 gm. of tannin per 500 cc. is required, and also a gelatin solution containing 10 grms. of gelatin, 5 grms. of alum, 10 grms. of boric acid per litre, which keeps better if shaken up with about 20 cc. of ether and a little chloroform.

100 cc. of the bark extract are taken as soon as possible after preparation, and to them are added about 5 grms. of sodium chloride; the mixture is gently warmed in a water-bath at about 40°, and gradually 50 cc. of the solution of gelatin are added. The whole is filtered, washed with water at 50°–60°, and dried at 110°. 100 cc. of tannin solution are treated in a similar manner. By comparing the weights of the two precipitates obtained, and knowing the strength of the prepared tannin solution, of course the strength of the extract is directly found. The method showed in medium oak bark 8–10 per cent. of tannin substance. The probable error is given at less than 5 per cent. of the value found. If the solution be allowed to stand the error becomes great.—T. L. B.

*New Method of Determining Tannin by Means of Iodine.* A. Moullade. J. Pharm. Chim. [5], 22, 153.

This is a modification of the method of Jean, whereby the tannin is determined by iodine in presence of sodium

bicarbonate. Instead of starch paste, carbon bisulphide is used as indicator. The iodine solution contains 5.2 grms. of iodine and 7.6 grms. of potassium iodide per litre; the sodium bicarbonate solution is 1 to 10. To determine the tannin value of the iodine solution, 10 cc. of an aqueous tannin solution (1 to 1000) are introduced into a stoppered bottle, then 20 cc. of the sodium bicarbonate solution and about 10 cc. of water, with also 2–3 cc. of carbon bisulphide. The iodine solution is run in from a burette, the flask being kept well shaken. Suppose 10.5 cc. of iodine solution have been run in before blue colouration of the carbon bisulphide manifested itself, a fresh experiment is then performed, running in this time 10 cc. of iodine solution all at once, shaking well; if no colouration appears, another trial should be made, running in this time 10.3 cc. If now blue colouration appear, a fourth trial must be made, this time running in 10.2 cc. of iodine solution. Supposing now the carbon bisulphide to remain colourless 10.3 is taken as the correct equivalent of 10 cc. of tannin solution = 0.01 gm. of tannin. In examining unknown tannin solutions with the iodine solution thus prepared, exactly the same plan is adopted; the amount of tannin in the solutions under examination should not exceed 1–1.5 gm. per litre, otherwise the amount of bicarbonate must be increased. To 10 cc. of solution 30 cc. of bicarbonate solution are added, and titration is immediately proceeded with in spite of any turbidity, which may be brought about by the bicarbonate. To ascertain the true quantity of tannin in all cases, when substances behaving in the same way as tannin are present, it is necessary to make two experiments, in one of which the tannic acid is precipitated by gelatin; the difference between the two titrations is the iodine corresponding to the tannin present.—T. L. B.

*Analysis of Butter and Margarin.* C. Violette. Compt. Rend. 111, 345–347.

By means of a current of steam the volatile fatty acids are distilled from about 50 grms. of butter, saponified by aqueous potash; not less than 10 litres of distillate are collected. By titration then the butyric and caproic acids may be ascertained; the solid volatile acids are washed, dried in vacuo and melted, and are weighed, as are likewise the non-volatile acids. The equivalents of these groups may be determined and calculated to the glycerides, so that in the end the composition of the butter is arrived at. To ascertain the respective amounts of butyric and caproic acid, suppose A to represent the quantity of butyric acid equivalent to the volatile acids, then the true quantities, B and C, of butyric and caproic acid respectively are given by the following:—

$$B = A \times 0.68469$$

$$C = A \times 0.41565$$

A number of analyses are given of samples ranging from good butter to margarin.—T. L. B.

*Examination of Gantter's Method for Estimating Tannin.* Von Schroeder and J. Paessler. Dingl. Polyt. J. 277, 361–377.

GANTTER'S new volumetric method (see Zeits. f. angew. Chem. 1889, 377–380; this Journal, 1889, 1015) is to some extent based upon the well-known method of Loewenthal (see this Journal, 1882, 509–510; 1884, 82, 524–526; 1885, 263–266; 1886, 79, 210; 1887, 51, 94, 388; 1888, 593, 647, 779; 1890, 260, 607), since in both methods the tannin is oxidised by potassium permanganate. But whilst in Loewenthal's method only a very incomplete oxidation of tannin takes place, and very dilute solutions of the substances to be tested are used, Gantter uses more concentrated solutions and employs heat. He claims for his method a complete oxidation of the tannin, and consequently greater accuracy. Moreover, Gantter's results with oak bark are almost identical with the estimations of tannin obtained by the indirect gravimetric method, whilst it is well known that Loewenthal's method gives only relative results, from

which the actual quantities have to be found by calculation. It is evident that the method would be of much higher utility than that of Loewenthal, if for all tanning materials the results were not only more uniform, but also in direct accord with the gravimetric method. But the authors remark at the outset that Gantter's method is to be preferred only to a limited extent to that of Loewenthal, and that it does not possess all the expected advantages.

To become completely oxidised to carbon dioxide and water, 1 part of tannin requires 1.71 parts of potassium permanganate (this Journal, 1890, 261). But in working with Loewenthal's process according to the method proposed by the commission for fixing upon a uniform method of tannin estimation (see Bericht der Commission, Cassel, 1885; this Journal, 1886, 79) only 0.85 parts of potassium permanganate are used for the incomplete oxidation of 1 part of tannin (until the colouration of indigo disappears). Although in Gantter's method the oxidation of tannin is carried much further, yet it is not complete, for 3.988 parts of potassium permanganate are in this case necessary for the oxidation of 1 part of tannin. It is clear from this that the oxidation in the case of Loewenthal's method is very incomplete, but it has been proved by many experiments that the method is nevertheless accurate, if the details be carefully followed. Gantter's idea in the use of heat and concentrated solutions, implies errors which are skilfully avoided by Loewenthal, for the great dilution of the liquid to be tested by the latter method is based on the fact that tanning substances are much more easily destroyed by potassium permanganate than many other organic substances which are often found associated with them. Soluble carbohydrates and certain organic acids have little or no influence on the accuracy of Loewenthal's test, and it is of no consequence whether they are absorbed along with tannin by hide powder or not. But in Gantter's method all such substances are more or less oxidised together with tannin by the permanganate solution, and errors in this respect are therefore unavoidable. Thus, it becomes clear that in all cases where such non-tanning substances are absorbed by hide powder along with the tannin, Gantter's method will not be applicable. The authors have found that Gantter's statement, that 3.988 parts of potassium permanganate are necessary for the oxidation of one part of tannin, is not correct under all circumstances, and this is quite natural, since the oxidation is not a complete one. Gantter has not defined the strength of the dilute sulphuric acid which he used in his tests, and it is probable that changes in the proportion of the acid will produce variations in the degree of oxidation. The authors have found that it is necessary to keep constant the proportions of tannin and sulphuric acid for accurate work. They propose to use 0.50 cc. of the above-mentioned dilute sulphuric acid for every milligramme of tannin. The results thus obtained were very satisfactory.

The total average of potassium permanganate necessary for the oxidation of 1 part of tannin is 3.999 parts, a figure which does not differ much from that recommended by Gantter. The following method of procedure is therefore recommended by the authors in employing Gantter's method:—A tannin solution of 1:500 is to be used. An equal quantity of dilute sulphuric acid (1:5) is to be added to from 10 to 25 cc. of the tannin solution, and the resulting liquid is titrated with potassium permanganate (4 grms. in 1,000 cc.), 1 cc. of which is equivalent to 1 mgrm. of tannin. The results prove that Gantter's method is superior to Loewenthal's for the volumetric determination of tannin, but in making experiments with different tanning materials, the oxidations were by no means so uniform as with tannin. If the details of the tests were not always strictly uniform (e.g., duration of times of boiling, of titration, &c.), the results varied considerably. Procter has made the same observation (see this Journal, 1890, 261). After having ascertained this, the authors successfully tried to make the method more accurate by carefully working uniformly in all the tests. At the close of the reaction a brown precipitate of manganese hydrate (compare this Journal, 1889, 1015) is formed, and since it is essential to boil the solution always the same length of time, the authors add the permanganate solution in single

cubic centimetres at a time, and boil in each case not longer than one minute. The test is finished at the moment when, after a minute's boiling, a thick precipitate of manganese hydrate has been formed. It is not difficult to ascertain this point. The determinations were made in the following way:—The liquid to be tested, mixed with dilute sulphuric acid as above described, is introduced into a flask of about 350 cc. capacity, and heated to the boiling point. Then potassium permanganate is added in single cc. and the mixture shaken for about 5 seconds after each addition. As soon as the red colouration no longer disappears when the liquid is shaken as described, the contents of the flask are heated once more to boiling, and the titration continued as before. As soon as the precipitate of manganese hydrate begins to appear the flask must be heated for one minute after each addition of potassium permanganate. Then about 5 cc. of permanganate solution are added, and the titration is finished by alternately adding oxalic acid and potassium permanganate (compare this Journal, 1889, 1015). For the sake of uniformity in all the tests, tanning materials were so extracted as to furnish a solution containing in 1,000 cc. about 2 grms. of tanning substances. For this purpose the following quantities were dissolved in 1,000 cc.:—20 grms. of oak bark and of pine bark; 7 to 10 grms. of mimosa bark, sumach, and quebracho; 5 to 7 grms. of valonia, Hungarian galls and myrabolans; 5 grms. of divi-divi and algarobilla; 3 to 4 grms. of solid quebracho extract (for further experiments it is recommended to take a little more of the last-named substance, and to increase the quantity of sulphuric acid proportionately). 10 cc. of these extracts as well as 10 cc. of the hide powder filtrates were in each case mixed with 10 cc. of dilute sulphuric acid and then titrated in the described way. It is difficult to understand how Gantter arrived at the conclusion that the hide powder filtrate is of no practical importance for the tests, as great differences occur by neglecting the latter, on account of the oxidation of the non-tanning materials present (compare Procter's remarks, this Journal, 1890, 261). Hide powder has been used as recommended by the commission for determining a uniform method of tannin examination (1885), viz., 3 grms. of hide powder, gently heated with 50 cc. of the solution for 18 to 24 hours. For comparison the same substances were analysed by the indirect gravimetric method (this Journal, 1888, 647). Seven different samples of oak bark were tested in this way, with good results.

Gantter's method and the gravimetric tests accord fairly well with each other, but it has to be noticed that Gantter's results are on an average lower by 1.031. They are, like Loewenthal's, only relative results for tannin, useful merely for comparing different samples of the same tanning material. But whilst Loewenthal's figures are always less than those obtained by the gravimetric method, it is a disadvantage of Gantter's method that the results vary, being sometimes more than the gravimetric results. But if (in Gantter's method) by comparison with the gravimetric method, reduction factors have been found, then the real results can be ascertained from the relative results obtained by titration. Gantter's method may be more limited in this respect than Loewenthal's, but its application for tanning materials is easy. This is shown by the small differences between the gravimetric and Gantter's method, if the results of the latter be multiplied by 1.031, which is the average figure by which Gantter's results are smaller than those obtained by the gravimetric method. Even the greatest difference, viz., that of 1.30 per cent., is not bad, compared with the differences which are often obtained in Loewenthal's method when the latter is not always performed in a thoroughly uniform manner. The authors state that the average differences with Loewenthal's method amount to 1.36 per cent. in their own laboratory, but even if the tests be made in exactly the same way, the differences may amount to more than 2 per cent. In working with Gantter's method such variations are much smaller, and the accuracy is therefore greater, its chief advantage being that it does not require so much experience, skill and care as Loewenthal's method does. It is therefore to be recommended for analysts who only occasionally have to make determinations of tannin. But an analyst who is constantly practising and well experienced in Loewenthal's process,

will derive no great advantage from Gautter's method. Hence each method has its proper sphere. In doubtful cases the indirect gravimetric method is always to be preferred.

The result of the thoroughly critical examination to which the authors have put the methods of Gautter and Loewenthal, is a conclusion that it would be best to admit only the gravimetric results as absolute, and to leave it to every analyst to arrive, by the best means he can adopt, at these results, either by the gravimetric method itself, or by calculations from Loewenthal's or Gautter's methods. In cases of dispute the gravimetric method should always be accepted as decisive. The results obtained from other tanning materials than oak bark by Gautter's method are contained in the following table:—

	1.	2.	3.	4.	5.	6.

These results differ considerably from the gravimetric method, but the authors have no doubt that by using special reduction factors for each substance, the method will be well adapted for the estimation of many tanning materials. It is added that the reduction factors given in the last table should first be confirmed by other tests before being used for technical purposes.—H. S.

#### Optical Analysis of Butter. C. Viollette. Compt. Rend. **111**, 348.

The following conclusions are drawn:—

(1.) That butter and margarin have different indices of refraction, varying within certain limits.

(2.) The indications of the oleo-refractometer are sufficient, provided the deviations for the various constituents of the mixture are known.

(3.) It is necessary to fix a limit of deviation below which all samples are considered margarin.

(4.) The oleo-refractometer is capable of being used in the examination of the commercial product, qualitatively only.—T. L. B.

#### A Method for the Quantitative Estimation of Camphor.

F. Foerster. Ber. **23**, 2981—2989.

The following method has been worked out especially in reference to the determination of camphor in ivorine, celluloid, and other solid products consisting of a mixture of camphor and nitrocellulose. When such a body is treated with caustic soda and the resulting solution distilled with steam, the camphor volatilises and may be readily dissolved out from the distillate by benzene. By determining the rotatory power of the resulting benzene solution, the quantity of camphor present can be found.

The author has in the first place investigated the relation of the rotatory power of a benzene solution of camphor to the quantity of camphor in solution. From Landolt's observations this ratio is expressed by the formula—

$$[\alpha]_D = (39.185 + 0.17084 C)^\circ$$

where "C" represents the degree of concentration, or the weight of substance contained in 100 cc. of the solution. Experimental results were not found to agree with this formula, and therefore fresh determinations were undertaken. The camphor used was purified by crystallisation from 50 per cent. alcohol, instead of by sublimation, as it was found that a certain amount of decomposition always takes place when the latter process is adopted; two recrystallisations were found to render it sufficiently pure. The purified product melts at  $176.3^\circ$ — $176.5^\circ$  when heated in a wide capillary tube; its point of solidification determined by Landolt's method was  $178.7^\circ$ ; it boils at  $209.1^\circ$  under a pressure of 759 mm. The formula deduced from the experiments, which are given in detail, is:—

$$[\alpha]_D = (39.755 + 0.17254 C)^\circ$$

Since—

$$C = \frac{100 a}{l [\alpha]_D}$$

where "l" is the length of the tube in decimetres it follows that—

$$C = 115.2052 \left( -1 + \sqrt{1 + 0.0436683 \cdot \frac{a}{l}} \right).$$

The determinations were made with a Laurent's half-shadow apparatus, using a water-jacketed tube 400 mm. long. The temperature was kept constant at  $20^\circ$ , to which temperature all the volumes employed were reduced, whilst all the weighings were reduced to their real value (i.e., in vacuum).

The following table of results shows the accuracy of the above formula:—

C found.	C calculated according to Formula.	Difference.
5	5.001	+ 0.0001
10	9.9824	- 0.0106
15	14.9982	- 0.0018
20	19.9915	- 0.0085
30	30.0037	+ 0.0037
40	39.9700	- 0.0300

To correct the above values for "C" to standard volume and a vacuum they can be multiplied by the factor 0.9966. For practical purposes this correction may be neglected.

The author has also studied the effect of temperature on the rotatory power of camphor dissolved in benzene, and finds that the latter increases with a rise in temperature, but that there is no simple relation between this increase and the temperature or degree of concentration of the solution. Tabulated results are given.

The actual determination of camphor in one of the already-mentioned substances is carried out as follows:—So much of the substance as corresponds to from 2—3 grms. of camphor are weighed out into a litre flask which is connected with a condenser and also provided with a dropping funnel. The receiver consists of a specially designed graduated vessel (see Figure), the lower bulb of which has a capacity of 150 cc., and the overlying, 1 cm. wide, graduated tube, a capacity of 30 cc. The decomposition is started by adding a 10 per cent. solution of caustic soda from the dropping funnel in sufficient quantity to saponify the product, the flask being heated on the water-bath to 80°. When the saponification is effected, a concentrated solution of caustic soda is then run in till the residue in the flask contains 10 per cent. of caustic soda. The contents of the flask are diluted, if necessary, to 250 cc. and then boiled, when the camphor distils over. The distillation is stopped when the lower bulb of the receiver is nearly full (120—150 cc.) and water added to the distillate up to the zero of the scale, which is at the bottom of the receiver tube. The condenser tube is then washed well with benzene and so much benzene is added to the contents of the receiver that the total volume (of benzene) is 25—30 cc. The small U-tube attached to the receiver (see Figure) is filled with benzene

during the experiment, to prevent any loss of camphor. The camphor is dissolved in the benzene by shaking the contents of the receiver, and the resulting benzene solution

is then ready for polarisation, after it has been brought to a temperature of 20° C. The method is accurate within 0.7—1.0 per cent. when pure camphor is employed. Two determinations of the camphor in celluloid gave 22.43 per cent. and 22.53 per cent.

For the determination of camphor in pharmaceutical preparations a slight modification of the process is desirable. Many of these preparations consist of a solution of camphor in fatty oils, in which cases the camphor is simply driven off by passing a current of steam through the oil, without the addition of any alkali. When the distillate amounts to about 300 cc. (a large flask is used as a receiver) it is treated with a little caustic soda and the distillation repeated under the conditions described above. The contents of the flask are apt to bump when heated, but a small platinum spiral prevents this. A trial of this method, using a 10 per cent. solution in camphor in olive oil, gave 98 per cent. of the total camphor contained.—C. A. K.

#### *Determinations of Alkaloids and their Molecular Weights.*

A. Christensen. Chem. Zeit. **14**, 1346—1352.

For determining ammonia, Kjeldahl has recommended a method of titrating the acid iodometrically. The author has applied this process with advantage for estimating alkaloids. He proceeds as follows: A weighed quantity of the alkaloid is dissolved in an excess of decinormal sulphuric acid and dilute alcohol made up with water to 50 cc. and 50 cc. of alcohol added. An excess of potassium iodide and iodate is added, which causes any excess of acid to react on these salts, setting iodine free. This is then titrated back with thiosulphate until the yellow colour of the solution disappears. If A cc. decinormal sulphuric acid were used, and a cc. decinormal thiosulphate solution, the molecular weight of the alkaloid being V, the quantity of the latter is  $\frac{V(A-a)}{10,000}$ , or the quantity of the alkaloid being found to be p, its molecular weight  $\frac{p \cdot 10,000}{(A-a)}$ .

Almost all alkaloids can be determined according to this method, the only exceptions being pilocarpine, narcotine, thiobromine, and caffeine, which is due to the ready dissociation of their sulphates. In the case of pilocarpine this may be prevented by titrating in aqueous solution; or in the case of narcotine the solutions should be thoroughly cooled.

Details of the carrying out of this process are given for the quinine, opium, and strychnine alkaloids, as well as for using it in the case of mixtures of different alkaloids.—A. R.

#### *The Estimation of the Sugars by Potassium Copper Carbonate Solution.* Part II. H. Ost. Ber. **23**, 3003—3011.

THE solution of potassium copper carbonate, the preparation of which has been previously described (this Journal, 1890, 825), has the following advantages over Fehling's solution:—It is very much more stable; it is much less reduced by cane sugar; slight departures from a particular mode of working cause less variation in the result, and consequently it is more easily managed; the amount of copper reduced by a given weight of sugar is from 1½ to 2 times as great; the different glucoses each reduce a different amount of copper; in using the solution volumetrically, the completeness of the reaction is sharply marked by the solution becoming completely colourless, and consequently no indicator is necessary.

In performing a gravimetric analysis, 50 cc. of the copper solution containing 298.7 mgrms. of copper are heated to boiling for 10 minutes with 25 cc. of the sugar solution. In a volumetric estimation, 50 cc. of the copper solution are heated with the amount of sugar solution needed to just decolourise the solution after 10 minutes' boiling. The volume of the mixed solutions should be about 75 cc.

Determinations have been made gravimetrically with the different glucoses. The following table contains a condensed synopsis of the results:—

Copper.	Invert Sugar.	Dextrose.	Levulose.	Galactose.	Arabinose.
Mgrms.	Mgrms.	Mgrms.	Mgrms.	Mgrms.	Mgrms.
50	15.2	15.6	14.7	17.4	17.0
75	22.3	22.9	21.7	25.9	25.1
100	29.5	30.3	28.5	34.5	33.1
125	36.8	37.8	35.4	43.1	41.1
150	44.0	45.3	42.5	51.8	49.3
175	51.5	52.9	49.5	60.8	57.5
200	59.1	60.8	57.0	70.3	66.2
225	67.5	69.2	65.2	80.3	75.4
250	76.7	78.4	74.4	91.2	85.5
275	87.1	89.9	85.9	103.3	97.1
298.7	100.0	102.5	99.0	117.0	109.5

The numbers in the last line show the amount of sugar required to completely precipitate 50 cc. of the copper solution, *i.e.*, the volumetric factors.

Lactose does not give such concordant numbers as the above glucoses, 198 mgrms. of lactose (hydrated) completely reduce 50 cc. of copper solution, that is reduce 298.7 mgrms. of copper, and 150 mgrms. of lactose reduce 231.2 mgrms. of copper.

The author has applied this mode of estimating sugar to the determination of the reducing power of hydrolysed lactose and raffinose.

The greatest reducing power of hydrolysed lactose is obtained by boiling 1 gm. of sugar with 80—90 times its weight of 0.6 per cent. hydrochloric acid for 5—8 hours. 50 mgrms. of the glucoses contained in such a solution when neutralised reduce 152—153 mgrms. of copper. If 25 mgrms. of dextrose and 25 mgrms. of galactose be submitted to the same treatment they reduce 149.7 mgrms. of copper.

Raffinose does not reduce potassium copper carbonate solution; when hydrolysed the highest reduction is obtained with 1.1 gm. of crystallised raffinose (containing 1.0 gm. of glucose) is boiled for 5 hours with 80—90 times its weight of 0.3 per cent. hydrochloric acid, 50 mgrms. reduce 150 mgrms. of copper. 50 mgrms. of a mixture containing equal quantities of dextrose, galactose and levulose submitted to the same treatment reduce 152.0 mgrms. of copper.—A. L. S.

*The Estimation of Cane Sugar.* C. O'Sullivan and F. W. Tompson. *Proc. Chem. Soc.* 1890, [88], 160.

THE authors describe a new method of estimating sucrose which they claim is applicable to all solutions containing cane sugar, including natural juices and other preparations in which the use of acids is not possible. The process is a very simple one, and it is shown, by comparing it with estimations in which invertase is used, that it is very accurate. It is based on the one used by Kjeldahl in 1881, and is as follows:—

The neutral solution containing cane sugar is placed in a constant-temperature bath at 55°. A little pressed brewer's yeast is added, and complete admixture secured by gentle stirring. At the end of four hours inversion is nearly always finished. The solution is cooled, made up to double its original bulk, and filtered. During the process there is a decrease in the optical activity of the solution, and an increase in the cupric reducing power. Each of these factors is an accurate measure of the amount of cane sugar originally present. The authors quote experiments showing that good results are thus obtained in solutions which would not admit of the use of acids.

*Determination of Mineral Matter in Sugar by Means of Benzoic Acid.* E. Boyer. *Compt. Rend.* 111, 190—192.

DIRECT incineration is a long and delicate process for which the process of Scheibler (incineration in presence of sulphuric acid) has been substituted. Correction is, however,

needed in this case, and it is a disputed point what this correction really ought to be. The author, therefore, proposes, instead of sulphuric acid, to use benzoic acid dissolved in strong alcohol. 5 grms. of sugar are moistened with 1 cc. of distilled water in a platinum crucible; the crucible is gently warmed, but not so that the sugar is carbonised, a little alcoholic benzoic acid solution is added, and the heating is continued, at first carefully, until the alcohol is all gone, then more strongly. The benzoic acid gives off a large amount of vapours, which swell out the sugar. When the benzoic acid has all volatilised there remains a voluminous residue of carbon. The crucible is then put into a muffle at a dull red heat for, say, half an hour, at the end of which time incineration should be complete, and a perfectly white ash should remain. The weight of ash represents the mineral matter contained in 5 grms. of the sugar.

Ammonium benzoate may be used instead of benzoic acid.  
—T. L. B.

*On the Estimation of Mineral Oil or Unsaponifiable Matter.* Fairley and Burrell. *Pharm. J.* October 18, 1890, 315.

IN the Yorkshire district large quantities of oil and grease are used in the woollen and leather manufactures and other purposes. Much of this oil is recovered and used again for the same or other operations. It is frequently found that these recovered oils and greases contain large proportions of mineral oil or unsaponifiable or resinous matter, which are not always readily estimated by the process given in text-books. The following process has, however, been found to succeed in these cases:—

Five grms., equivalent to nearly 80 grains of the oil, are weighed out, saponified with alcoholic potash (about 80 grms. of KHO in 1,000 cc. of alcohol), evaporated in a basin on the water-bath to pastiness, then dissolved in from 45 to 50 cc. of warm water and treated in a separating funnel with an equal volume of ether and 2 to 3 cc. of alcohol and shaken 3 to 4 minutes. On standing the ethereal solution which comes to the surface is decanted and evaporated. A second treatment with ether is unnecessary, because, as a rule, the results with a single extraction are correct within 0.1 and 0.2 per cent.

The points in this process are—1. Keeping the aqueous solution of the soap within a volume not exceeding (for 5 grms. of oil) 50 cc. 2. Treating with an equal volume of ether in one operation, at a temperature of near 90° F. Then the ethereal solution of the mineral oil separates, and, in all successful experiments, is very nearly equal to the volume of ether employed. 3. Washing this ethereal solution with warm water in the separator, which can be done very quickly. 4. When the residue, left after evaporation of the ether and drying, has been weighed, it should always be distilled in a small tube retort. If it distils unchanged, without blackening or formation of acrolein, it is free from soap or ordinary fats.

The peculiar bitter after-taste and fluorescence of oils containing mineral oil are also of importance.

The following results were carried out by the above process, and by different operators:—

No.	Mineral Oil.	Per Cent.
1	A.....	16.40
	B.....	16.24
2	A.....	17.87
	B.....	17.60
3	A.....	18.85
	B.....	18.60
4	A.....	32.8
	B.....	31.4
5	A.....	35.50
	B.....	35.36

*On the Estimation of Cotton-Seed Oil in Lard.* Fairley and Cooke. Pharm. J. October 18, 1890, 315—316.

For this purpose Beech's test, when carefully worked, gives useful results, which can be confirmed by the observation of the heat given out in mixing the samples with a definite proportion of sulphuric acid.

Attempts have been made to apply the specific gravity test; and Bockairy, in a recent number of the *Bulletin de la Société Chimique* (3rd series, ii., 310), takes the density of the lard at 50° C. = 122° F. He finds that unadulterated lard varies little in density at this temperature, and that there is a sufficient difference between the density of lard and cotton-seed oil to give a means of approximate quantitative estimation.

Bockairy gives the following numbers:—

	Density at 50° C.
Lard, highest.....	*8915
Lard, lowest.....	*889
Lard, mean.....	*890
Very rancid lard.....	*8895
Oleo-stearine.....	*8885
Rend fat of the ox.....	*8895
New cotton-seed oil.....	*897
Old cotton-seed oil.....	*896

#### *New Cotton-Seed Oil and Lard.*

Cotton-Seed Oil.	Lard.	Density at 50° C.
0	100	*890
10	90	*8915
20	80	*892
30	70	*8925
50	50	*894
75	25	*8953
100	0	*897

Careful experiments fully confirm the utility of the method and prove that it may give a most valuable confirmatory test.

The following is a list of results:—

*Examination of Olive Oil.* G. Meyer. Chem. Zeit. **14**, 1202.

DETERMINATIONS are made of the specific gravity, of polarisation, of bromine absorption, and of saponification value.—T. L. B.

### ANALYTICAL AND SCIENTIFIC NOTES.

*The Diffusion of Carbonic Anhydride through Caoutchouc.* E. Obach. Chem. Zeit. **14**, 1142.

On emptying one of Kipp's carbonic acid apparatus for the purpose of recharging, which had been fitted with a disc of brown unvulcanised rubber, to prevent small particles of marble from falling into the acid in the lowest bulb, the author noticed some large blisters, one of which was egg-shaped, with a diameter of 2 cm., and projected only on one side of the disc; another extending equally on both sides. When exposed to the air, these blisters gradually became smaller, the former diminishing to a diameter of 16 mm. after an exposure of 25 minutes. The rubber sheet from which the disc was cut had evidently been made by rolling together two thinner sheets, and the adhesion not being perfect in some places, air had entered, to be afterwards replaced by carbonic acid. (See also this Journal, 1890, 1072.)—F. H. L.

*Relative Stability of Salts, whether isolated or in presence of Water.* Berthelot. Compt. Rend. **111**, 135—144.

STRONG acids and strong bases are characterised by the fact that their union gives rise to a much greater development of heat than the union of weak acids and bases; by reason of this circumstance the salts of strong acids and strong bases are the more stable; that is to say, in the isolated condition they, as a rule, resist the action of heat and the decomposing action of water better than salts from weak acids and weak bases.

In comparing the heats of formation of various series of salts, it is found that the differences between the heats of formation of solid salts of the same base, united with two distinct acids, is approximately constant for equally strong acids; whilst the difference is more uncertain where salts of

weak acids are concerned. This points to instability in these salts. Like phenomena occur in the case of bases. Similar differences are observable with solutions of salts, and they show the dissociation existing amongst salts of weak acids and bases, compared with salts of strong acids and bases.

In the present memoir salts of aniline are examined in solution. In sulphate of aniline, ammonia, it is shown, displaces the aniline completely; soda replaces equally ammonia, and there is here a "series," confirmed by the respective heat reactions.

Acetate of aniline shows a much greater degree of dissociation than ammonium acetate does.—T. L. B.

*On Silk Secretion by Bombyx Mori.* R. Dubois. *Compt. Rend.* **111**, 206—207.

THE name *fibroin* has been given to the central portion of the thread of the cocoon and also to the viscous contents of the centre of the silk gland. Both, however, differ materially; the latter, for instance, being soluble in potassium carbonate (15 to 100), the former not. It has been suggested that the fibroin of the gland undergoes on exit a coagulation similar to that which the white of an egg undergoes when heated; it has further been considered, that desiccation or oxidation may have something to do with the phenomenon in question. The author reduces the probability to the consideration of coagulation and then shows that the coagulation is not to be compared to the coagulation of albumen by heat, but rather to the coagulation of blood. A kind of serum is obtained by macerating silk glands for two or three days in a cool place with distilled water, or with salt solution (4 to 100), or with potassium carbonate solution (15 to 100). This serum is filtered, and is then agitated; a clot forms without addition of any reagent. The clot presents the ductility and elasticity of silk on exit from the duct, but it quickly loses the property whereby it admits of being spun. It fixes a portion of the yellow colouring matter contained in solution in the artificial plasma, and resists the action of reagents which dissolve the contents of the gland before coagulation. As is the case with blood, oxygen aids the formation of the clot, for when the air in the experimenting vessel is replaced by carbon dioxide or hydrogen a clot is certainly still obtained on agitation, but if this be filtered off and the filtrate shaken again, this time in contact with air, a further clot will be obtained.—T. L. B.

*The Colouration of Silk by means of Coloured Food given to Silkworms.* L. Blanc. *Compt. Rend.* **111**, 280—282.

See under V., page 1125.

## New Books.

**ASBESTOS.** Its Properties, Occurrence, and Uses, with some Account of the Mines of Italy and Canada. By ROBERT H. JONES. London: Crosby, Lockwood, and Son, 7, Stationers Hall Court, Ludgate Hill. 1890.

OCTAVO volume, bound in cloth, price 12s. 6d., containing Frontispiece, Preface, Table of Contents, List of Illustrations, and Text. The Text covers 226 pages and concludes with an Alphabetical Index. The pages of this volume are exceedingly well illustrated by eight colotype plates and 39 engravings.

The matter is sub-divided into Chapters treating of the following details, and prefaced by an Introductory Chapter. Chap. I. Varieties and Qualities of Asbestos. II. Present Sources of Supply. III. Italian Asbestos and the Italian Mines. IV. Canadian Asbestos. V. The Canadian Mines

or Quarries. VI. Output, Cost of Production, Wages, &c. VII. Newfoundland and Norway. VIII. The Uses of Asbestos for Engineering Purposes. IX. Applications of Asbestos to Military and Fire Preventive Purposes. X. Miscellaneous Applications of Asbestos. XI. Substitutes and Similarities. XII. Fibre Spinning.

In the preface the author states his object in writing this book as being the preparation of "a synopsis of all that is known on the subject of asbestos generally, so that those who, like himself, are interested in this singular mineral, may find all the details ready to hand without the expenditure of the labour and time he has had to give in looking them up."

**SUGAR ANALYSIS.** For Refineries, Sugar Houses, Experimental Stations, &c., and as a Handbook of Instruction in Schools of Chemical Technology. By FERDINAND G. WIECHMANN, Ph.D. New York: John Wiley and Sons, 53, East Tenth Street. London: Kegan Paul, Trench, Trübner and Co., Ltd. 1890.

OCTAVO volume bound in cloth, price 10s. 6d. The work is dedicated to the author's teacher, Professor Ch. F. Chandler, of Columbia College, and consists of a systematic treatise on the physical and chemical methods for determining the strength and constituents of sugars and sugar juices, &c. It commences with a Preface, followed by Table of Contents, and Subject-Matter covering 181 pages. An Alphabetical Index concludes the work. Pages 116 to 181 are entirely devoted to tables of strengths, constants, &c. There are five wood engravings of a simple character.

The contents are sub-divided as follows:—Chap. I. Physical Apparatus required in Sugar Determinations. II. Sampling Sugars and Molasses. Determination of Colour of Sugar and Sugar Solutions. Determination of Densities, Alkalinity, and Acidity. Test for Sulphurous Oxide in Sugar. III. Determination of Sucrose in absence of other Optically Active Substances. Optical Analysis. Quotient of Purity or Exponent. Gravimetric Analysis. IV. Determination of Sucrose in the Presence of other Optically Active Substances. Clerget's Inversion Method. Sucrose in the Presence of Raffinose and Dextrose. Sieben's Process for Destruction of Lævulose. Determination of Sucrose, Dextrose, and Lævulose. V. Invert Sugar. Qualitative and Quantitative Determination. Volumetric and Gravimetric Methods. Soldani's Solution. VI. Water. Ash. Quantitative Analysis of Sugar Ash. Suspended Impurities. Determination of Woody Fibre. Detection of the Sugar Mite. VII. Organic Non-sugar. Classification of Organic Bodies accompanying Sucrose. Schemes for the Analysis of the Organic Acids. Determination of Total Nitrogen. Non-nitrogenous Organic Substances. Determination of Pure Cellulose. VIII. Notes on the Reporting of Sugar Analyses. Rendement. Calculation of Rendement. Duty. Calculation of the Weight of Solids and Liquids from their Specific Gravity. Chapter IX. contains a valuable list of References to Literature on Sugar Analysis.

**CHEMISCH-TECHNISCHES REPERTORIUM,** Uebersichtlich Geordnete Mittheilungen der neuesten Erfindungen, Fortschritte und Verbesserungen auf dem Gebiete der technischen und industriellen Chemie mit Hinweisen auf Maschinen, Apparate, und Literatur. Herausgegeben von Dr. EMIL JACOBSEN. 1889. *Erstes Halbjahr, Zweite Hälfte.* Berlin: R. Gaertner's Verlagshandlung, Hermann Heyfelder, S.W. Schönebergerstrasse, 26. London: H. Grevel & Co., 33, King Street, Covent Garden.

THE first issue for the second half-year of 1889. It contains 107 pages of subject-matter, copiously illustrated with wood engravings. In the text the following subjects are treated of:—Building Materials, Cements, Artificial Stone. Colours, Dyeing and Calico Printing. Fats, Oils, Illuminating and Heating Materials. Fermented Liquors. Tanning, Leather and Glue Manufacture. Textiles, Glass, and Earthenware. Wood and Horn. India-rubber. Cements, Plasters, Artificial Stone. Lakes, Varnishes and Paints. Metals.

GRUNDZÜGE DER THEORETISCHEN CHEMIE. VON LOTHAR MEYER. Leipzig: Druck und Verlag von Breitkopf und Härtel. 1890.

OCTAVO volume in paper cover, dedicated to Professor Franz Neumann. Dedication. Preface. Table of Contents and 200 pages of subject-matter. The work concludes with an Alphabetical Index and a table exhibiting the Natural System of the Elements. This abridged form of a work so well-known as Lothar Meyer's "Modern Theories of Chemistry" will be very welcome to students or those who desire a more condensed account of the subject. Although Ostwald's "Grundriss der allgemeinen Chemie" might appear to cover precisely the same ground, in reality it does no such thing, as the author points out, and there is consequently room for the abridgments of both well-known and complete works.

#### ERRATUM.

In the November number of this Journal, 1890, page 1074, second column, "*Report on Analyses and Research conducted in 1886-1889 in the Central Chemical Laboratory of Italian Customs*," &c., for the first paragraph substitute the following:—This report is addressed to Senator Cannizzaro.

## Trade Report.

### BOARD OF TRADE NOTICE.

#### TENDERS FOR THE PURCHASE OF ANTIMONY ORE FROM THE SERBIAN GOVERNMENT.

The subjoined translation of a note issued by the Serbian Minister of Commerce, inviting tenders for the purchase of certain antimony ore, has been received from Her Majesty's Minister at Belgrade, and was issued from the Foreign Office on the 2nd December.

On the 28th December next (9th January 1891) there will be publicly sold at the Mining Section of the Royal Department of Commerce and Agriculture, to the highest bidder, 100,000 kilos. of antimony ore from the Government mines of Podrinje. The conditions of sale, as well as the analysis of the above-mentioned ore, will be on view every day from 11 to 12 at the said office for (the convenience of) those concerned. Ten thousand francs (400*l.*) in cash must be deposited as caution money. Tenders must be sent in by noon on the 28th December (9th January 1891) at the latest, with all particulars in accordance with prescribed conditions.

### TARIFF CHANGES AND CUSTOMS REGULATIONS.

#### ROUMANIA.

##### *The Importation of Vegetable Oils.*

Sir F. C. Lascelles, Her Majesty's Minister at Bucharest, in a despatch to the Foreign Office, dated the 22nd November, encloses translation of a regulation published in the official *Monitor*, stating that the importation of vegetable oils can only take place at the following Custom houses in Roumania:—Jassy, Galatz, Braila, Giurgevo, Ploesci, Bucharest, Severin, and Craiova. The reason given for the issue of this regulation is that the greater part of the

vegetable oils which are imported into Roumania are adulterated; that it is not easy to detect the adulteration; and that it is only at the Custom houses named that a proper analysis can be made.

#### ARGENTINE REPUBLIC.

##### *Tariff Changes.*

*Note.*—Dollar = 4*s.* (nominal). Litre = 0.22 Imp. gallon.

The Hon. F. J. Pakenham, Her Majesty's Minister at Buenos Ayres, in a despatch to the Foreign Office, dated the 27th October, forwards a statement of amendments in the Argentine Customs tariff, which had been put to the vote in the Senate, and passed. The following chemicals are mentioned in the statement in question:—

Imports to pay, *ad valorem*:—

50 per cent.—Gunpowder, perfumery.

45 per cent.—Wooden matches, rockets.

40 per cent.—Tanned leather.

15 per cent.—Dynamite.

10 per cent.—Paper, cement.

5 per cent.—Sulphuric acid, sulphate of lime, zinc, lead.

25 per cent.—All articles not specified as above.

Special import duties are as follows:—

Starch, 90 dollars per ton, refined.

Sugar, 90 dollars per ton; kerosine, 5 cents. per litre; candles, 18 cents. per kilo.

Free of duty.—Quicksilver, sulphur, benzene for combustion, and sheep dips.

#### EQUADOR.

##### *New Customs Law.*

*Note.*—Kilogramme = 2.204 lb. avoirdupois. Sucre = 4*s.* 2*d.* (nominal value).

The following are from a translation of a new law passed by the Government of Ecuador, making various modifications in the Customs tariff and regulations forwarded in the report of Mr. G. Chambers, Her Majesty's Consul at Guayaquil, dated the 3rd October last:—

New articles free of duty.—Powdered sulphur, carbolic acid, and chloride of lime.

New articles at 1 cent. per kilo.—Dynamite or gunpowder for mines, wood charcoal, common sheet glass.

New articles at 2 cents. per kilo.—Tubes of iron, lead, clay or porcelain, carbonate of potash, caustic soda.

New article at 5 cents. per kilo.—Machine grease.

New articles at 50 cents. per kilo.—Powder made up into artificial fireworks, slippers and other rubber articles.

New export dues.—The export dues upon each 100 kilos. of the following will be:—

Rubber, 5 suere; mangrove bark, 0.64 cents.; hides, 0.64 cents.; orchilla, 0.64 cents.; tanned hides, 1 suere.

### EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

#### FRANCE.

##### *Tartaric Acid.*

The manufacture of tartaric acid in Marseilles has received a considerable impetus from the establishment of a new factory. In 1888 the output in that city was about 400 tons; in 1889 it reached 800 tons.

#### JAPAN.

##### *Fine Chemicals.*

The Japanese are now trying to manufacture iodide of potassium themselves. Among new remedies sulphonal and chloralamide have been introduced as hypnotics in 1889.

Of the former small quantities have been sold; the latter has not yet been able to gain a footing. Among antipyretics, antipyrin and antifebrin have maintained their position; phenacetin and exalgine have also been tried, but have not as yet found any sale whatever. In santonin very little business was done during 1889, as the Japanese, owing to the high quotations for that preparation, use the raw worm-seed, which can be bought at 7 dols. per picul. Of amorphous phosphorus, French and Russian makes have been introduced in competition with the English, but thus far without the same success as the first named. The excessively stringent inspection of all imported chemicals in the Government laboratories still continues, and from all those not strictly in conformity with the Japanese Pharmacopœia the official stamp, without which they may not be sold in Japan, is withheld.

The following were among the quantities imported into Yokohama in 1889 (the figures representing cetties of 1½ lb.):—Potassium bromide, 32,170; potassium iodide, 21,206; glycerin, 58,821; gum arabic, 116,444; carbolic acid, 25,900; caustic soda, 1,289,903; cinchona, 34,524; phosphorus, 11,626; salicylic acid, 15,224; santonin, 5,029; tartaric acid, 15,199. In addition to these the imports of quinine were 47,332 oz., and of morphia, 6,736 oz. Of unenumerated raw drugs, 83,514 yen; of medicines and fine chemicals (unenumerated), 402,587 yen; and of dye-stuffs, 745,802 yen value were also imported.

#### MEXICO.

##### *Drugs and Duties.*

The following figures represent the imports of drugs and chemical products into Mexico during the first half of the fiscal year 1888—89, from the four principal markets of supply:—

Imported from	United States.	United Kingdom.	France.	Germany.
Drugs, value, dols. ..	476,756	40,949	117,652	50,304
Duties payable on these, dols. ....	318,498	24,408	56,878	29,208
Or per cent. ....	66½	59½	47½	58½

#### RUSSIA.

##### *Customs Regulations.*

Stringent, and in many cases vexatious, Customs regulations continue to be strictly enforced. The attention of shippers cannot too urgently be called to the necessity of conforming to the Russian Customs regulations in every particular, to avoid "accidence" fines and penalties connected with incorrect description of weight and quantity of goods in bills of lading. A translation of the Russian regulations has been published by the Board of Trade, and all firms interested in the trade with this country are recommended to provide themselves with a copy. During the last navigation season, 10 British vessels were obliged to pay fines varying from 10*l.* to 20*l.* for contravention alone of the rule which makes the production by shipmasters of bills of lading imperative on the arrival in a Russian port.

##### *Drugs at Nijni-Novgorod.*

The great fair of Nijni-Novgorod, in 1889, was, on the whole, a successful one. Among other goods a good business is reported to have been done in drugs, indigo, and olive oil. Of drugs, dyestuffs, and paints, 5,565,750 roubles' worth were brought to the fair, against 5,479,850 roubles in 1888.

#### BRAZIL.

##### *Drugs for Bahia.*

The following is the value of pharmaceutical imports (in lbs.) into Bahia during the last five years:—

	1885.	1886.	1887.	1888.	1889.
Plants and herbs. ....	24,369	20,215	44,739	32,689	48,175
Perfumery, dyes, &c. ...	\$9,563	54,108	114,479	99,391	85,494
Chemical products. ....	14,664	30,033	69,509	41,824	38,199
Surgical instruments. ...	1,973	1,177	2,344	1,932	1,375

#### ITALY.

##### *The Naples Oil Industry.*

There are in the province of Naples 140 oil mills, all working on very antiquated principles—not a single one being a steam mill. A total of 780 workmen are employed in them. They work on an average 38 days every year, and produce an aggregate of 4,200 hectolitres of olive oil.

##### *Chemicals.*

In the same province there are 31 chemical works, employing 373 hands. Sulphuric and nitric acids, matches, soap, and blacking are the principal products.

#### PERU.

##### *Coca.*

Two establishments exist in Peru for preparing cocaine from the coca-leaf, one in Lima and one in Callao. During 1889, 1,730 kilos. of cocaine were exported to Europe, principally for Germany. No statistical data are forthcoming concerning the amount of production of leaves, but in the year 1888, 28,660 kilos. were exported through the port of Callao.

#### MISCELLANEOUS TRADE NOTICES.

##### REPORT FROM BAKU.

##### *Chem. Zeit.* 14, 1393.

An unusual naphtha spring has been discovered at Bina-gadi, near Baku, oil being struck at a depth of only 55 m. From St. Petersburg new laws are announced regulating the naphtha industry. Foreigners and Jews are only allowed to engage in the work by special permission of the Court. Trial borings must be covered in, and sufficient tank accommodation for the crude naphtha provided, to avoid waste of material.—F. H. L.

#### THE MINERAL RESOURCES OF INDIA.

The following interesting information respecting the mineral resources of India is extracted from the *Times of India* for the 25th October:—

Though less interesting than iron, in that they do not affect the greatness of the country so much, the baser metals of India are of especial interest from the antiquity of their development, and the fact that to a large proportion of the inhabitants they have, practically, been the only useful metals known. The noble metals, as gold and silver are called, have been used almost entirely for ornament and coinage. Platinum, really a precious metal, more valuable even than gold, is generally found with the latter, though rejected by the native gold washers of the Indus Valley as *safed sona* and valueless. It has never yet been discovered in large quantities in India, and except in the Indus Valley and the Kolar gold-fields, we have no evidence of the discovery of more than traces of the metal. Mercury,

though thoroughly understood in this country, does not seem to have been discovered in any large quantities, though the persistent rumour that asserts its plentiful presence in the Andaman Islands can hardly be without some basis. The probable explanation may be in a discovery of cinnabar in the Little Andaman, which has, as yet, never been thoroughly searched, as its rocks of the early tertiary period interspersed with volcanic "faults" closely assimilated to those of the great mercury beds of California. The author of "Hamilton's East Indies" saw in 1694 a native who had brought much mercury from the Little Andaman (of which he was a native) to the Nicobars. It has been discovered in Cannanore in spots of pure metal in a bed of laterite, but never seems to have been much developed. Pure mercury is brought from Afghanistan, said to be obtained from Pir Kisee, some 250 miles beyond Kandahar. The trade, however, has never reached any importance. Of the baser metals proper, by far the most important and valuable is copper, as it is also, perhaps, the oldest known in Asia. There are mines now unused that appear to be of great antiquity, showing in this as in many other things how greatly the people of India have deteriorated in scientific knowledge. Where formerly the extraction and smelting of copper ores was carried out on a large scale, we now see petty workings that yield before every reverse of nature. The largest copper workings in India are those of the Singhbhum district, extending as they do for over 76 miles from Midnapore to Lohardugga. It is believed that the Jains started mining in this district over two thousand years ago, since which they have never quite ceased work.

In the Goomacunda Valley, in the Karnaul district, there exists a deserted copper mine, so old that the very legend of its workers has been lost to the people living there. In the Hazaribagh district there are also deserted copper mines and large mounds of copper slag, showing that the ore was smelted on the spot. Ore is found here, which would probably repay any attempt at systematic working. The chief secrets of success in Indian mining seems to be: 1st, working on a scientific basis so as to waste neither metal nor labour; and 2nd, utilising native labour wherever possible, and obtaining European foremen who can teach their men the practical use of their tools.

The Khetri mines, as they are called, including those of Kullari and Singhana, are still worked, and of great antiquity. They resemble nothing so much as a rabbit-warren, the galleries, such as they are, winding about after the metal and being little bigger than absolutely required to admit the bodies of the miners. Large quantities of blue vitriol and coppers are extracted from the refuse of the mines, and these "refuse products" are at least as valuable as the actual ore itself as at present extracted; but this is becoming a not uncommon feature of modern manufacturing industries. Flooding is the great danger of the Kullari galleries, as the only means of clearing them from water consists of a string of men with *ghurras*. The Singhana mine must have paid well in former days, for the miners paid 14,000 rupees a year to the Khetri rajah as the rent of the mines, in addition to one-sixth of the copper mined. It is thought that copper mining in the Hazara district would be profitable; but the question of carriage would be a serious one, though the ore is extremely rich, being in this respect far superior to that found in Kumaon. The Nepalese do a good deal of copper mining in a small way, their ore yielding about  $4\frac{1}{2}$  per cent. of copper. The Hazara ores are said to have yielded from 60 to 90 per cent. of copper from the picked ore, but we feel utterly disinclined to accept these figures. They probably were obtained, if obtained at all, from small and excessively rich selected pieces, and are by no means a fair sample of the whole. Possibly by "copper" is meant "regulus," which in itself only yields 50 per cent. of copper. Even the smallest pieces of ore could not yield 90 per cent. of pure metal. Next to copper, its common alloys, zinc and tin, are the most interesting of the baser metals. Zinc is only found to any extent in Oodeypore, where the Jawar mines were formerly worked on a large scale, and yielded a yearly revenue of nearly 2½ lakhs of rupees. At present no extensive zinc workings exist in India, though possibly the

indications of the metal at both Sirmur and Tavoy might yield profitable results to scientific development. Tin, on the contrary, is found on a large scale in several places, though the fact that the natives of India have used brass universally for centuries seems to point to the presence of zinc in some form or another possibly imported. Tin occurs chiefly as a dioxide, the tin stone containing as much as from 75 to 80 per cent. of metallic tin. In 1867 the native iron smelters of Raniganj smelted some of the tin stone, supposing it to be iron ore, and when they saw white metal, mistook it to be silver. Burmah is the greatest Indian source of tin. It is worked by the Karens in the hill, near the Salwin, and sold by them in Tounghu. In the Tenasserim division, tin stone is very plentiful, every stream bed near Malceewoon in Mergui yielding the metal when washed. Dr. Oldham states that the main source of all the Tenasserim tin is the granite range separating that province from Siam, where "it exists as an essential ingredient of the mass of rock, occurring disseminated through the granite in small crystals, and being similarly arranged to the quartz and felspar. . . . The degradation of this granite by weathering through an enormous period of time has supplied the sand which is now so abundantly impregnated with stream tin."

At Mergui it used to be worked in the very gardens of the town, and in the Thawhawleek River there have been extensive stream washings for years, the fine sand being sorted out with a cane shovel that acts like a large sieve, and finally washed in wooden dishes, in which the tin sinks by its own weight on the water being revolved. The only European attempt to work Burmese tin on a considerable scale was made between 1873 and 1877, when Messrs. Steel and Sons leased the township of Malceewoon, where they not only washed the stream tin but opened out veins of ore in the hills. During the cold weather of 1874—75 some seven tons of metal and 14 tons of cleaned picked ore were exported. The works were, however, closed in 1877. It is worthy of note, however, that since the European workers failed, the Chinese have found the mines remunerative, and are still at work there, though they pay a ground rent and a royalty of 5 per cent.

From a manufacturing point of view, tin naturally suggests lead, and no mining industry, except iron, shows such a falling off as that of the working of lead mines. Galena, the sulphide of lead, is common in many parts of India, but Cuddapah and Karnaul are probably richest in the ore. In Cuddapah, at the village of Judgmrazpilly, close to the Nallamallay Hills, the old lead workings are conspicuous.

A sample of ore from these regions was analysed in 1879, and yielded 78 per cent. of lead and 22 oz. 7 dwt. of silver to the ton of lead. Both these and the Karnaul mines would probably repay scientific exploitation handsomely. Three analyses of ore from the latter yielded, respectively, 374 oz., 175 oz., and 165 oz. of silver to the ton, which would render them well worth working. In Bengal galena has been found in the Southall Peggannahs and also in Bhagalpore. An analysis of ore found in the latter district showed 78 per cent. of lead and 103 oz. of silver to the ton. Hazaribagh, so rich in metals, yields also galena, and in 1880 a company was formed in Bombay to work this district; but it came to nothing. Ajmere, Sirmur, and Tenasserim would also yield profitable results.

#### SOLVAY AND CO.'S ALKALI WORKS.

According to the Journal of the Dutch Society for the Promotion of Industry, the production of soda in the combined works of Messrs. Solvay & Co. has risen from 3 ewt. in 1864—when it was first commenced—to 400,000 tons in 1889. The latter figure represents about one-half of the world's consumption. The Société Solvay & Cie. owns, in addition to the immense works at Conillet and Vaugeoisville-Dombasle in France, three factories in Germany (Sarralbe, Wyhlen, and Bernburg), one in Russia (Beresniki), one in Austria (Ebensee), and one in the United States (Syracuse).

**SULPHURIC ACID AND MANGANATE OF SODA  
CONTRACTS.**

At its meeting on Tuesday the London County Council accepted the tender of Messrs. C. Tennant, Sons, & Co. for the supply of 1,000 tons of manganate of soda at 16*l.* per ton, and of the Widnes Alkali Company (Limited) for the supply of 600 tons at 15*l.* 15*s.* per ton. The Council also accepted the tender of Messrs. Sadler & Co. for the supply of 1,000 tons of sulphuric acid at 1*l.* 14*s.* per ton.

**DISCOVERY OF NICKEL ORE.**

A rich vein of nickel ore has been discovered at Frankenstein, in the Kosenmetz Hills. Herr Krupp, the ironfounder, has made an offer of one and a half million marks to the finders and owners of the ore, but they refuse to sell the whole vein. They have, however, undertaken to supply Herr Krupp with 2,000 cwt. of it.—*Ironmonger.*

## Monthly Patent List.

\* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

### I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

#### APPLICATIONS.

18,596. E. J. Hardy. Improvements in the production of cold and ice, and in apparatus therefor. November 18.

18,751. O. Schulz. Improvements in continuous evaporating apparatus. Complete Specification. November 20.

19,071. O. Imray.—From A. Bergh, Denmark. A method and apparatus for subjecting liquids having substances suspended in them to centrifugal action, whereby they are brought into contact only with sterilised or with other air, with which they are to be saturated. November 24.

19,110. J. A. Morrell. Improved methods of and apparatus for evaporating and concentrating solutions. Complete Specification. November 25.

19,199. J. Kent. An improvement in thermometers. November 25.

19,550. J. Kirkaldy. Improvements in apparatus for heating and evaporating liquids. December 1.

19,587. F. Soxhlet. A method of closing bottles suitable for sterilised liquids. Complete Specification. December 1.

19,667. C. C. Leathers.—From W. Radam, United States. New or improved retort for the manufacture of patent medicines. Complete Specification. December 2.

19,736. A. Hart. Improvements in or relating to vessels and appliances for boiling, infusing, steaming, washing, and bleaching purposes. Complete Specification. December 3.

19,835. H. J. Allison.—From The National Salt and Chemical Co., United States. Improved apparatus for the vapourisation of liquids. Complete Specification. December 5.

19,979. J. Cox. An improved apparatus for storing and discharging liquid and compressed gases. December 8.

19,981. H. Cotton. Improvements in the construction of mills for grinding flint stone, bone, glaze, and other like substances. December 8.

20,095. H. Roeske. Improvements in apparatus for the filtration of liquids. Complete Specification. December 9.

20,133. S. Rushton, E. Blades, and W. Holden. An improved grinding or crushing mill for pulverising or reducing salt. December 10.

20,166. F. M. Robertson. Improvements in the process of and apparatus for evaporating and drying. December 10.

20,309. E. C. C. Baly. An improvement in mercury vacuum pumps. December 12.

20,318. E. Cohn. Improvements in and relating to sterilising apparatus. Complete Specification. December 13.

20,351. W. Dewar. An improved condenser. December 13.

#### COMPLETE SPECIFICATIONS ACCEPTED.\*

1889.

19,096. T. Williams. Means and appliances for production of pure carbonic oxide gas. December 3.

20,049. D. Herman. Apparatus for concentrating solutions and drying substances. December 10.

1890.

606. J. Brock and T. Minton. Filter presses. December 3.  
1242. R. A. Kemp. Apparatus for containing material for absorbing moisture. November 26.

1948. H. W. Deacon and V. C. Driffield. Apparatus for separating liquids from solids. December 10.

2055. B. J. B. Mills.—From A. Siegle. Apparatus for heating liquid and gaseous bodies. December 10.

2207. W. Scollay. Means for regulating admission of gas and air to Bunsen burners. December 17.

7886. T. Norman and H. T. Simpson. Improvements in furnaces to promote combustion. December 17.

8295. B. Versen. Production of refractory linings for converter bottoms, and apparatus therefor. December 10.

17,718. H. H. Lake.—From E. Bolton. Distilling and condensing apparatus. December 10.

### II.—FUEL, GAS, AND LIGHT.

#### APPLICATIONS.

18,488. R. E. Slade. Improvements in fire-lighters. November 17.

18,618. T. A. Greene and C. M. Walker. Improvements in gas-lighting. November 18.

18,639. P. S. Hyslop. Apparatus for utilising liquid fuel for the production of motive power for heat motors. November 18.

18,640. P. S. Hyslop. Apparatus for producing and storing under pressure combustion gases from solid fuel for use as motive power in heat motors. November 18.

18,681. E. J. Duff. Improvements in the manufacture of gas from oils and water vapour. November 19.

18,825. J. Staincliffe. Improved means for charging and discharging retorts employed in the manufacture of gas. November 21.

18,871. H. Williams, of The Illuminating, Heating, and Power Gas Company, Limited. Improvements in the method of and in apparatus for burning gas for heating and steam generating purposes. November 21.

18,872. H. Williams, of The Illuminating, Heating, and Power Gas Company, Limited. Improvements in gas generating apparatus. November 21.

18,949. J. Raines, jun., and G. Raines. An improved fire-lighter. November 22.

18,991. R. F. Strong. An improved smokeless fuel. November 22.

19,067. S. Clarke. Improvements in the manufacture of night-lights. November 24.

19,219. H. C. Bull. Improvements in and connected with the manufacture of combustible gases from coal and analogous substances, and in and connected with the production of sulphate of ammonia from the product of the process of manufacture. November 26.

19,501. F. J. Jones. Improvements in the manufacture of coke, in obtaining by-products therefrom, and in apparatus used therefor. November 29.

19,543. J. Wilson, jun. Improvements in the consumption of smoke. December 1.

19,553. V. B. Lewes and W. W. Staveley. Improvements in the manufacture or production of illuminating gases. December 1.

19,732. W. C. Owston. Improvements relating to the purification of smoke, and the collection of by-products therefrom. December 3.

19,761. T. Proud. An improvement in wooden grids for gas purifiers. December 4.

19,888. J. Love. Improvements in and relating to the manufacture of gas, and to apparatus therefor. December 5.

19,963. A. Vinaard. Producing and supplying gas for lighting and motive power, and apparatus therefor. December 6.

20,002. A. Dauber. A gas generator. Complete Specification. December 8.

20,030. L. Van Vestraut. Improvements in apparatus for charging inclined gas retorts. December 9.

20,033. T. S. Forster. The economising of fuel. December 9.

20,658. J. Turner. An improved method of conversion or treatment of small coal, smudge, shale, and other organic matter and refuse, and the apparatus therefor. December 9.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1890.

1349. W. L. Wise.—From E. Solvay and L. Semet. Gasification of fuels and apparatus therefor. December 3.

9956. R. Kennedy. Heating by electricity. December 3.

17,000. J. J. Thomas. Coal-gas generating apparatus. December 3.

17,151. B. F. Field. An artificial fuel and the method of manufacturing the same. December 3.

17,466. H. H. Lake.—From The Standard Coal and Fuel Co. A compound for treating fuel. December 10.

17,470. H. H. Lake.—From The Standard Coal and Fuel Co. A compound for treating fuel. December 10.

17,484. H. H. Lake.—From The Standard Coal and Fuel Co. A compound for treating fuel. December 10.

#### III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

##### APPLICATIONS.

19,502. A. M. Clark.—From The Gewerkschaft Messel, Germany. Production from mineral oils of sulphonic acids and sulphones, and the manufacture of a new product for treating gelatinous matters with sulphonic acid. November 29.

19,943. W. W. Staveley. Improvements in the production of hydrocarbons of the aromatic series from blast-furnace, coke-oven, or coal-tar oils, or from crude phenols or phenoloid oils or compounds (such as are obtained from these oils). December 6.

#### IV.—COLOURING MATTERS AND DYES.

##### APPLICATIONS.

18,526. J. Imray.—From La Société L. D. Huguenin and Cie., Switzerland. Manufacture of colouring matters obtained by the action of amines of the fatty series upon galloxy-anine. Complete Specification. November 17.

18,527. O. Imray.—From the Firm J. Curtius, Germany. Process and apparatus for the manufacture of ultramarine. November 17.

18,623. H. H. Lake.—From Wirth and Co., agents for A. Leonhardt and Co., Germany. Improvements in the manufacture of colouring matters. November 18.

18,637. B. Willecox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture of new anthraquinone dyestuffs. November 18.

18,729. B. Willecox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture of new derivatives of anthraquinone. November 19.

19,016. A. E. Delacroix. The improvement of lactic acid and its salts in the application of colouring matters. November 24.

19,065. S. Pitt.—From L. Cassella and Co., Germany. The production of sulphonated thionines, and dyestuffs therefrom. November 24.

19,167. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik, Germany. Improvements in the manufacture of sulpho-acids of a red basic naphthalene dyestuff. November 25.

19,330. S. Pitt.—From L. Cassella and Co., Germany. The preparation of colouring matters with gamma-amido-naphtholsulphonic acid. November 27.

20,252. H. H. Lake.—From Wirth and Co., agents for A. Leonhardt and Co., Germany. Improvements in the manufacture of chemical compounds. December 10.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1890.

569. A. Kern and E. Sandoz. Blue colouring matters. December 17.

1579. J. Imray.—From La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis, A. F. Poirrier and D. A. Rosenstiehl. Manufacture of azo-amines by reduction of azo-colouring matters derived from nitranines. December 3.

1699. O. Imray.—From The Farbwerte vormals Meister, Lucius, and Brünig. Manufacture of colouring matter of the induline series, soluble in water. December 8.

1808. O. Imray.—From The Society of Chemical Industry, Basle. Production of yellow basic colouring matter. November 26.

1811. R. Holliday. Manufacture of colouring matters. December 10.

1812. R. Holliday. Manufacture of colouring matters, and dyeing or printing fibres therewith. December 10.

1874. J. Imray.—From La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis, and Dr. Chapuis. Production of soluble blue colouring matters of the induline class. December 17.

2499. H. H. Lake.—From K. Oehler. Manufacture of soluble blue cotton dyestuff. December 3.

#### V.—TEXTILES, COTTON, WOOL, SILK, Etc.

##### APPLICATIONS.

18,585. J. Davidson. Improvements in the use or application of thistle down. November 18.

18,955. J. Palmer. Improvement in the treatment of resinous or gummy fibres. November 22.

19,252. C. D. Abel.—From the Firm of Philips and Mathée, Germany. Process for cleansing or purifying woollen fabrics. November 26.

20,257. A. H. Briggs. An improved method of and apparatus for scouring, drying, and stretching mohair, alpaca, and such like wools and yarns. December 12.

20,267. A. Ambler, S. Ambler, and F. Ambler. Improvements in cleansing, treating, or washing wool and like animal fibres, and in apparatus employed therein. December 12.

20,334. D. Barnett. Improvements in apparatus for treating textile vegetable substances to obtain fibres therefrom. December 13.

## COMPLETE SPECIFICATION ACCEPTED.

1890.

1461. J. Smith, I. Smith, and J. Smith. Method and apparatus for scouring wool and other fibres. November 26.

# VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

## APPLICATIONS.

18,700. J. B. Whiteley, E. Whiteley, A. Armitage, and W. Cleland. Improvements in the method of and apparatus for dyeing wool, cotton and other fibre, and also "tops" and slivers of fibre. November 19.

19,158. P. J. Grandsire. Improvements in machines for dyeing skeins or hanks. November 25.

20,274. E. Knecht. An improved method of mordanting mixed goods of cotton and wool. December 12.

## COMPLETE SPECIFICATIONS ACCEPTED.

1890.

1062. S. Knowles and J. Knowles. Production of azo colours upon cotton or other vegetable fibres in the piece, and apparatus therefor. November 26.

1607. J. Smith, I. Smith, and J. Smith. Method and apparatus for mordanting and dyeing wool, cotton, and other fibre, and for separating animal from vegetable fibre. December 17.

1812. R. Holliday. See Class IV.

1813. R. Holliday. Dyeing textile fibres. December 10.

2411. T. Ingham. Dyeing cotton. December 17.

17,872. T. Salzmänn. Production of dyed cotton yarns and threads. December 10.

# VII.—ACIDS, ALKALIS, AND SALTS.

## APPLICATIONS.

18,835. J. Simpson. Improvements in the manufacture of caustic soda, with the recovery of reagents employed for repeated use. November 21.

18,990. J. Greenwood. Improvements in the manufacture or production of chlorine and caustic soda, and in apparatus therefor. November 22.

19,089. G. E. Davis and A. R. Davis. Improvements in apparatus for the manufacture of sulphate of ammonia. November 25.

19,121. T. Needham. Improvements in the packing or putting up of chloride of lime and other substances. Complete Specification. November 25.

19,316. J. C. Richardson. Improvements in chloridising lime. November 27.

19,390. M. N. d'Andria. Improvements in the manufacture of ammonium chloride and calcium sulphate. November 28.

19,776. J. Simpson. Improvements in the manufacture of chlorine. December 4.

19,792. M. Netto. Improvements relating to the production of ferrate of sodium, and to the manufacture of caustic soda therefrom. December 4.

19,815. F. M. Lyte and O. J. Steinhart. Improvements in the production of chlorine. December 4.

20,012. F. Ellershausen. Improvements in the treatment of soda waste. December 8.

## COMPLETE SPECIFICATIONS ACCEPTED.

1890.

448. F. M. Spence, D. D. Spence, and A. Esilman. Manufacture of alum. December 10.

984. H. Grimshaw. Compound for generation of carbon dioxide. December 10.

1016. F. Ellershausen. Manufacture of soda and potash. December 10.

1524. G. Wischm. Method of vaporising solutions containing nitrates of manganese, and means for decomposing the said nitrates. December 10.

5058. E. Delplace and J. Delplace. Manufacture of sulphuric acid. December 10.

6758. J. McEwen. Process and apparatus for continuous generation of carbonic acid gas from a soluble carbonate and an acid in solution. December 17.

15,648. J. Leith. Production of sulphhydrate of calcium to be used in the manufacture of alkali and sulphuretted hydrogen, and apparatus therefor. December 3.

# VIII.—GLASS, POTTERY, AND EARTHENWARE.

## APPLICATIONS.

18,940. J. Hartley. Improvements in apparatus for annealing rolled plate glass. November 22.

19,340. H. R. Lumley. Improvements in the manufacture of sheet or plate glass and other glass-ware. November 27.

19,342. W. Ambler. An improved method and means to be used in the manufacture of glass bottles. November 27.

19,532. D. Rylands. Improvements in the manufacture of hollow glass and other ware, and of the caps for such ware. December 1.

19,594. G. Bosselier. Improved methods of preparing "Mosaic" and other slabs, tiles, medallions, and like articles. December 1.

19,717. J. P. Bayley.—From C. Ulfig, United States. Improved method of joining parts of glass-ware. December 3.

19,798. A. T. Wedelin. Improvements in furnaces and implements for annealing glass. December 4.

20,207. C. F. Bailey. Improvements in or relating to saggers used in firing pottery-ware. December 10.

20,240. F. E. Grant. A process relating to the application of coloured designs to vitreous surfaces, and machinery therefor. December 10.

## COMPLETE SPECIFICATIONS ACCEPTED.

1890.

1803. L. Appert. Moulding glass, and apparatus therefor. December 17.

2626. C. Huelser.—From J. Kemper. Producing opalescent glass or enamel from a glass mixture containing silico-fluorides of alkalis or compounds thereof. December 17.

13,436. F. C. Roberts. Pottery kilns. December 17.

14,983. J. T. King.—From E. Jones and J. A. Jones. Apparatus for manufacture of glass-ware. November 26.

16,112. W. Boulton. Machinery for manufacturing cups and other articles in pottery-ware. November 26.

17,952. A. J. Boulton.—From H. Thumler. Manufacture of glass chains. December 17.

## IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

### APPLICATIONS.

18,518. J. Wilson. An improved plaster called "Terra-Tinta." November 17.

18,603. T. Arnold. Improvements in or relating to the manufacture of cement, and the means employed therefor. November 18.

18,732. A. Cajot. Improvements in apparatus for the enriching of phosphate of lime, and of phosphated chalks for the preparation of cements, marls, and starches, and for similar purposes. Complete Specification. November 19.

18,774. J. T. Welch and W. J. Owen. Improvements in the utilisation of granite and other kindred rocks in the manufacture of bricks, tiles, and other articles. November 20.

18,899. L. C. Delahaye. An improved method of enriching phosphated chalk and other calcareous phosphates. November 21.

18,924. A. F. E. de St. Dalmas. Improvements in and relating to paving blocks. Complete Specification. November 21.

18,992. W. Smartt. Improvements in the process of drying or burning bricks, pipes, tiles, and other goods in clamps, kilns, and other works, and in apparatus for effecting the same. November 22.

### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

20,303. C. Smith.—From G. P. V. Nielsen. Artificial asphalt. December 17.

1890.

2371 and 2371A. C. H. Edwards. Manufacture of certain bricks and fireclay substitutes. December 10.

7107. J. P. Bayly.—From P. Arnold. Paving blocks. December 10.

## X.—METALLURGY, MINING, ETC.

### APPLICATIONS.

18,508. J. Johnson.—From J. W. Langley, United States. Improvements in aluminium alloys, and in the manufacture thereof. November 17.

18,546. F. H. Molesworth. Improvements in the construction of rotary furnaces for the calcination of sulphide and other ores. Complete Specification. November 17.

18,604. L. L. Burdon. Improvements in compound gold wire. Complete Specification. November 18.

18,605. L. L. Burdon. Improvements in compound hollow metal ingots and wire. November 18.

18,636. R. Hadden.—From G. Conkling, United States. A new or improved process for concentrating iron ore. Complete Specification. November 18.

18,673. A. J. Spiller. Improvements in bronzing brass and other alloys. November 18.

18,718. D. Jenkins. Improvements in machinery or apparatus to be employed in coating metal sheets or plates with tin or other metal or alloy. November 19.

18,726. M. R. Garcia. Improvements in the method and process for the recovery of tin from tinned plate and other sources. Complete Specification. November 19.

18,869. A. Gutensohn. An improved method of and process for annealing metal plates and sheets, and apparatus for use in the same, and for other purposes. November 21.

18,898. T. D. Nicholls and The Cape Copper Company, Limited. An improved method of extracting copper from ores or compounds containing the same. November 21.

18,900. A. Coehn. An improved method of producing castings of aluminium or its alloys. November 21.

18,915. W. P. Thompson.—From C. H. Land, United States. Improvements in or appertaining to the manufacture of compound aluminium plates. Complete Specification. November 21.

18,932. R. Starke and W. Paterson. Improvements in the extraction of metals from ore. November 22.

18,933. R. Starke and W. Paterson. Improvements in the extraction of metals from ore. November 22.

18,934. W. Paterson and R. Starke. Improvements in the extraction of metals from ore. November 22.

19,163. H. W. Lash and J. Johnson. Improvements in the reduction of ores. Complete Specification. November 25.

19,164. J. Johnson. Improvements in the reduction of ores. Complete Specification. November 25.

19,179. J. C. Bayles. Improvements in the art of uniting iron or steel plates or sheets by welded joints. Complete Specification. November 25.

19,180. J. C. Bayles. Improvements in the method of and apparatus for welding together the meeting edges of iron or steel sheets or plates. Complete Specification. November 25.

19,181. J. B. Hannay. An improved process and apparatus for extracting gold from minerals containing it. November 25.

19,572. W. P. Hopkins. Improvements in manufacturing iron. Complete Specification. December 1.

19,646. T. Smith and J. B. Hamond. Improvements in the process and in apparatus for manufacturing metallic cement. December 2.

19,707. L. Joret. Improvements in means for stopping tapping holes of cupolas and blast furnaces, especially those used for "ferromanganese" and "spiegel." December 3.

19,734. J. Y. Johnson.—From A. Imbert and G. Juillien, France. Improvements in the manufacture of iron and other metals, and apparatus therefor. December 3.

19,756. G. W. Hart. Reducing haloid mineral ores, and obtaining metals, oxides, and carbonates therefrom. December 4.

19,875. R. Nahusen. Improvements in the extraction of gold, silver, copper, and other metals from ores or substances containing the same. December 5.

19,910. J. Heydon. Improvements in the means and apparatus for making the moulds in which metals are to be cast. December 6.

19,940. W. D. Bohm. Improvements in the extraction of gold and silver. December 6.

20,160. T. C. Sanderson. Improvements in smelting ores of antimony, and in furnaces and crucibles therefor. December 10.

20,393. H. C. S. Dyer. Improvements in the manufacture of steel. December 13.

### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

19,687. T. Teague. Treatment of tin refuse or slag. December 3.

20,181. T. Young. Treating ores to obtain precious metals, and apparatus therefor. December 10.

20,264. A. Gutensohn. Annealing metal plates and sheets. November 26.

20,380. J. E. Bott. Manufacture of compound armour plates. December 17.

20,587. J. Lysaght. Galvanising apparatus. November 26.

1890.

213. J. Mackintire. Manufacture of steel and iron. December 10.
316. J. E. Chaster. Extraction of metals from ore. December 10.
560. T. Twynam. Manufacture of copper. December 10.
859. W. White. Production of aluminium. November 26.
1053. H. Grimshaw. Recovery of zinc from galvanised iron and steel. December 3.
1443. J. T. King.—From C. Adams. Reduction of metallic ores, and apparatus therefor. December 3.
1522. T. H. Johns. Apparatus for coating hoop iron with tin or terne metal. December 17.
1624. A. H. Holdich. Stopper or valve for controlling the flow of steel from the ladle or reservoir used in steel works. December 3.
2390. J. Buchanan, jun. Precipitating gold or silver in the process of extraction. December 10.
5407. O. Lumaghi. Apparatus for reduction of argenteriferous or other zinc ores. November 26.
5847. C. Wood. Process and apparatus for manufacturing fibrous material from slag or other vitreous substances. November 26.
8295. B. Versen. *See Class I.*
8572. T. L. Thomas and J. B. Hillman. Process and appliances for galvanising metals.
- 14,053. F. A. Herbertz. Smelting furnaces. December 17.
- 16,060. L. Grabau. Obtaining metallic sodium. December 3.
- 17,613. P. M. Justice.—From J. Meyer. Manufacture of steel and ingot iron. December 10.

## XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

### APPLICATIONS.

- 18,491. R. Kennedy. Improvements in dynamo electric machines. Complete Specification. November 17.
- 18,523. H. Zerener. Improvements in apparatus for heating, welding, melting or gasifying solid bodies by electricity. November 17.
- 18,625. H. H. Lake.—From H. Lemp, United States. Improvements in and relating to apparatus for use in electric welding, forging, and other metal-working operations. Complete Specification. November 18.
- 18,631. H. H. Lake.—From E. Thomson, United States. Improvements relating to the welding of metals by electricity. Complete Specification. November 18.
- 18,661. J. T. Niblett. Improvements in the construction of plates for secondary batteries. November 18.
- 18,896. A. S. Elmore. Improvements in the process and apparatus for manufacturing copper tubes, sheets, strips, and wires by electrolysis. Complete Specification. November 21.
- 19,052. M. N. Mallison. Improved combination of ingredients constituting a compound as an illuminating medium for electric incandescent lamps. November 24.
- 19,155. H. H. Lake.—From G. E. Hatch, United States. Improvements in electrical storage batteries or accumulators. Complete Specification. November 25.
- 19,162. M. W. Dewey. Improvements in methods of electric welding and metal working. Complete Specification. November 25.
- 19,203. L. Hausmann. Improvements in the manufacture of thin metal tubes by electrolysis. November 25.
- 19,344. E. Placet and J. Bonnet. Improvements in electrolysis in general, and particularly in electrolysis of metals. November 27.

19,423. E. A. Ducretet. Improvements in apparatus for the electrolytic production of gases. November 28.

19,650. Siemens Bros. and Co., Lim.—From Siemens and Halske, Germany. Improvements in the distribution of electricity through accumulator batteries. December 2.

19,942. W. P. Thompson.—From F. Marse, Germany. Improvements in galvanic batteries, and in the electro-chemical formation of chlorine and chlorine-compounds applicable for such batteries and other purposes. Complete Specification. December 6.

20,102. A. S. Baxendale. An improvement in dynamo-electric and electro-dynamic machines. December 9.

20,111. H. H. Lake.—From L. L. Roberts and T. H. McGraw, United States. Improvements in apparatus for use in the electrolytic decomposition of metallic salts. Complete Specification. December 9.

20,126. C. E. Dutton, jun. Improvements in galvanic batteries. Complete Specification. December 10.

20,193. The Electrical Inventions Co., Lim., and E. Andreoli. Improvements in or relating to the electro-chemical extraction of gold, silver, and other precious metals from their ores. Complete Specification. December 10.

20,401. E. Andreoli. Improvements in the electrolysis of chloride and other solutions. Complete Specification. December 13.

### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

19,813. H. Wernsdley and H. Foster. Heating, melting, and working metals, alloys, and metalloids, by electricity; and apparatus therefor. November 26.

1890.

488. M. Sappey. Primary batteries. December 17.
8933. G. H. Felt. Method and apparatus for depositing metals electrically. December 10.
9956. R. Kennedy. *See Class H.*
- 16,522. G. D. Burton. Method and apparatus for working metals by electricity. November 26.
- 16,571. C. W. Kennedy and H. Groswith. Secondary batteries. November 26.

## XII.—FATS, OILS, AND SOAP MANUFACTURE.

### APPLICATIONS.

- 18,801. C. Billing. Improvements in or appertaining to the manufacture of soap. November 20.
- 19,066. C. F. Leake, H. W. Godfrey, and C. E. Lucas. Improved process for oxidising linseed and other oils. November 24.
- 19,070. O. Inray.—From the Firm of C. Spiegel, Russia. Process and apparatus for the production of castor oil. November 24.
- 19,382. J. Taylor. Improvements in the treatment of soapmakers' waste lyes for the recovery of glycerin and other substances. November 28.
- 19,960. P. Wild. Process and apparatus for smelting margarine, tallow, or other crude fatty substances by means of hot air. Complete Specification. December 6.
- 20,164. D. Clarke. Clarke's improved method for manufacturing chemical detergents. December 10.

### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

- 13,700. C. Billing. Manufacture of soap. December 3.

1890.

1109. H. Noerdlinger. Obtaining valuable products from press and extraction residues of oil manufacture. December 3.

1652. R. D. Barnett. Extracting oil and grease from cotton waste, &c. December 10.

2446. A. and E. des Cressonnières. Manufacture of kneaded or agglomerated soaps. December 3.

### XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

#### APPLICATIONS.

18,609. J. Bond. Improvements in driers. Complete Specification. November 18.

19,072. O. C. Strecker. Improvements in the manufacture of sealing wax, blotting wax, and the like. November 24.

19,160. M. E. Dejonge. Improved anti-corrosive and anti-fouling compounds. Complete Specification. November 25.

19,275. R. C. Anderson. An improved manufacture of paints or varnish for coating leather and cloth. November 26.

19,323. W. Smith and W. Elmore. Improvements in the manufacture of basic carbonate of lead or white lead. November 27.

19,730. H. Meier. An improved compound applicable as paint, paste, or the like. December 3.

19,784. W. Smith and W. Elmore. Improvements in the manufacture of basic carbonate of lead or white lead. December 4.

20,145. A. F. St. George. An improved method of treatment of gum-resins and resins, and manufacturing varnishes. December 10.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

19,910. J. E. Wood. Manufacture of white pigments, chiefly composed of sulphate of lead. November 26.

20,707. R. Mullard. Manufacture of paints and varnishes; treatment of gums and resins for same, and for preservative and decorative purposes; also for preserving plates and bottoms of ships from corrosion and fouling. December 3.

1890.

764. W. H. Barnes. Compositions to be used as paints. November 26.

13,719. E. Schmal. Medium for use with chemical and earth colours. December 3.

15,857. C. M. Higgins. Printing or stamping inks. December 3.

15,858. C. M. Higgins. Printing or stamping inks. December 3.

### XIV.—TANNING, LEATHER, GLUE, AND SIZE.

#### APPLICATIONS.

18,602. J. Broadhurst. An improved compound or size for fixing colours upon wall papers and the like. November 18.

19,216. C. L. Lawrence. Making leather boards, leather board soles, pulp board and soles, upper leather and sole leather, and soles waterproof. November 26.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1890.

981. H. Grimshaw. Recovery of tannin from waste leather. November 26.

17,853. T. O. Butler. A glue compound. December 10.

### XV.—AGRICULTURE AND MANURES.

#### APPLICATION.

20,310. R. Stone. Improvements in the manufacture of artificial manure. December 12.

#### COMPLETE SPECIFICATION ACCEPTED.

1890.

2265. J. Pipe and H. D. Andross. Compound for treating vines and plants for prevention and destruction of phylloxera, mildew, &c., and method of producing same. December 17.

### XVI.—SUGARS, STARCHES, GUMS, ETC.

#### APPLICATION.

20,181. H. Maenillan. Improvements in apparatus for evaporating, concentrating, or distilling saccharine liquids or such like. December 10.

### XVII.—BREWING, WINES, SPIRITS, ETC.

#### APPLICATIONS.

18,540. J. C. Fell.—From F. Tiedemann, Denmark. An improved apparatus for the continuous charging of liquids with carbonic acid gas. November 17.

18,652. A. J. Boulton.—From H. Lissagaray, France. Improvements in or relating to the manufacture of wine-spirit. November 18.

18,708. J. Cox. Improvements in brewing beer. November 19.

18,762. A. Blake. An improvement relating to fermentation of brewers' wort. November 20.

18,804. A. E. Favre and G. Savourat. Improvements in the treatment or application of Indian corn or maize for brewing purposes. November 20.

20,073. R. Genge and Sigmund Bros. Improvements relating to the production of dry yeast, cattle food, and spirit from vegetable products containing starch. Complete Specification. December 9.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1890.

1809. H. T. Brown, G. H. Morris, and E. R. Moritz. Manufacture of amyloins for the treatment of beer. December 10.

1996. J. F. Littleton. Method and apparatus for rousing beer and mixing or blending wort or gyle. December 10.

16,951. H. Bates, jun. Corn product for brewers' use, and manufacture thereof. December 3.

# XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

## APPLICATIONS.

### A.—Chemistry of Foods.

18,627. J. W. Gordon.—From A. E. Wright, Australia. Improvements in the preparation of milk for dietetic purposes. November 18.

18,745. W. Cole. Improvements in the manufacture or production of butter. November 19.

19,168. E. Luck, R. Pott, and N. Pott. Improvements in the treatment of cereals for preventing or arresting decomposition, and for preserving or improving the condition thereof. November 25.

19,178. O. Imray.—From The Mosquera Julia Food Co., United States. Improvements in the manufacture of psin and peptonised food products. Complete Specification. November 25.

### B.—Sanitary Chemistry.

18,983. W. E. Adney. Improvements in the purification of sewage and other waste liquors, and in the recovery of ammonia therefrom. November 22.

19,628. R. S. Browldow. Improvements in apparatus for the treatment of sewage, parts of which are applicable to apparatus for purifying water for manufacturing and other purposes. December.

19,764. W. H. Mellor. Improvements in destructors or furnaces for burning towns' refuse. December 4.

19,967. R. Cunliffe and E. Vow. Improvements in the method of and apparatus for treating towns' slaughter-house, and other refuse or substance or material. December 8.

## COMPLETE SPECIFICATION ACCEPTED.

### A.—Chemistry of Foods.

1889.

19,882. H. Barotte. Process and apparatus for production of dry extract of coffee. December.

1890.

192. J. H. Hooker. An alimentary liquid. December 3.

982. H. Grimshaw. Producing infusions, &c., free from tannin. November 26.

2060. H. A. Snelling. Treating hops, blending same for infusion together with tea, cocoa, &c. December 10.

16,362. G. F. Redfern.—From E. Scott and A. Scheehong. Preservation of bread, &c., apparatus therefor. December 10.

17,245. B. Willeox.—From the Rumford Works. Baking powders, &c. December 3.

17,427. B. G. Hudnut. Corn products, &c., for manufacturing the same. December 17.

### B.—Sanitary Chemistry.

1890.

1170. C. A. Brown. Furnaces for burning refuse material. November 26.

16,972. F. P. Candy. Method and material of sewage and polluted water or liquids. December.

17,686. E. W. Cracknell. Furnace for garbage and refuse. December 10.

17,687. E. W. Cracknell. Process and apparatus for treatment of night-soil and noxious matters.

## C.—Disinfectants.

1890.

1589. C. T. Kingzett. Manufacture of disinfectants, insecticides, and sanitary reagents. December 3.

# XIX.—PAPER, PASTEBOARD, ETC.

## APPLICATIONS.

18,838. A. A. Haigh. Improved waterproof paper. November 21.

19,523. F. L. Leech and A. Horrobin. Improvements in means for waterproofing paper in the process of manufacture. December 1.

19,545. J. W. Bretherick. Improvements in machines or appliances used in the manufacture of paper. December 1.

## COMPLETE SPECIFICATIONS ACCEPTED.

1890.

1087. T. Goodall. Apparatus for incineration of black liquor and spent soda lyes used in the boiling of esparto grass and other fibres. November 26.

11,021. J. B. Atherton.—From L. D. Beck. Manufacture of Manila paper. December 10.

# XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

## APPLICATIONS.

19,074. J. Y. Johnson.—From F. von Heyden, Nachfolger, Germany. Improvements in the manufacture and production of medicinal compounds for ethereal oils. November 24.

18,576. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning, Germany. Manufacture of a compound of antipyrine and iodine. December 1.

20,252. H. H. Lake.—From Wirth and Co., agents for A. Leonhardt and Co., Germany. See Class IV.

20,261. J. Bertram. Process or processes for obtaining the two isomeric monomethylethers of protocatechuic aldehyde. December 12.

# XXI.—PHOTOGRAPHIC PROCESSES AND MATERIALS.

## APPLICATIONS.

19,402. A. W. Scott. Improvements in the method of and apparatus for producing photographs, and in displaying them or the like. November 28.

19,658. A. J. Boulton.—From G. Eastmann, United States. Improvements in photographic films. Complete Specification. December 2.

## COMPLETE SPECIFICATION ACCEPTED.

1890.

16,238. H. H. Beale. A scarlet liquid for the treatment of negatives, by means of which clouds can be made, and other useful and artistic effects produced. December 17.

## XXII.—EXPLOSIVES, MATCHES, Etc.

## APPLICATIONS.

18,519. J. S. Walter. Improvements relating to explosive compounds. Complete Specification. November 17.

19,076. W. M. Mordey. Improvements in electric safety fuses. November 24.

19,125. W. M. Nix. Improvements in the manufacture of friction matches. Complete Specification. Filed November 25. Date applied for April 10, 1890, being date of application in United States.

19,259. G. G. André. Improvements in the manufacture of gunpowder, and in apparatus therefor. November 26.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

20,286. E. W. Anderson. Apparatus for cutting smokeless explosives or plastic material into lengths. December 17.

1890.

1995. W. P. Thompson.—From J. Hess. Improvements in lucifer matches. November 26.

2547. J. Y. Johnson.—From C. Pieper. Manufacture of explosives. December 3.
